OCCUPATIONAL HAZARDS IN A PUBLIC AMBULANCE SERVICE (Abstract): **Aim:** To identify the occupational risks in an ambulance service and to assess their impact on the health of employees. **Material and methods**: Two marched groups (number, sex, age, length of exposure) from two different work sectors were selected. A 60 item questionnaire was used. The 60 items were grouped into four categories related to work organization, work environment, neuropsychosensorial risk factors and health system and occupational safety-related risk factors and hazards. The data were statistically processed, significant correlations between the risk factors and the associated symptoms being found. **Results and discussion:** Compared to the control group, significantly higher values ($p<0.001$) for work complexity, work environment factors, and organizational risk factors (walking on uneven ground, carrying weight, vicious postures) were found in ambulance service staff; cervical and lumbar spine problems were the most common complaints of ambulance service staff. **Conclusion**: The specific risk factors for ambulance service employees directly related to musculoskeletal disorders have been established. **Keywords**: OCCUPATIONAL HEALTH, AMBULANCE SERVICE, RISK FACTORS, OCCUPATIONAL MUSCULOSKELETAL DISORDERS.

From the total employees of the European Union, 10% work in the health and social protection system. Healthcare is a field characterized by many occupational hazards, the most specific ones being ranked as follows: biological hazards, musculoskeletal constraints, psycho sensory and chemical risks. The public ambulance system, by the wide range of services (prehospital emergency care, outpatient care, transport of biological and non-medical products, 24 hours a day) and increasing number of accepted claims, is a job characterized by multiple occupational health hazards for its staff (1, 2, 3).

MATERIAL AND METHODS

Two groups were selected: group I included 50 emergency medical service staff members (24 females and 26 males), average age and exposure time of 49 years and 26 years, respectively: stretcher bearers (25), nurses (21) and physicians (4); group II (control group) included 50 school employees (8 primary school teachers, 37 middle school and high school teachers, 2 nurses, 3 janitors). The groups were marched for sex, age and average exposure time.

A 60-item questionnaire was selected following a recent and extensive review of

the literature relating to occupational hazards faced by health staff in general and the ambulance services staff in particular (2, 4, 5). The questions were related to occupational constraints imposed by: work environment (noise, microclimate, vibration, toxic substances etc.), work organization (exertion level, work demands, posture and position during work), psycho sensory constraints and other symptoms arising from the practice of profession, as well as assessments of occupational health and security system. The statistical analysis (chi^2, odds ratio, confidence interval) made possible obtaining highly significant correlations between risk factors and associated symptoms.

RESULTS AND DISCUSSION

By analyzing the data on work organization, most respondents (87% and 90%, respectively) have a fixed work schedule (8 h/day schedule established by the management with 48 consecutive hours off work in each week for ambulance service staff working night shifts). Thirty-eight percent of ambulance service employees occasionally work on Sundays, public holidays and/or night shifts compared to 5% in education.

There were no significant differences between the responses regarding the work skills and human relations, the responses of both groups being favorable. Differences were recorded between the two groups with regard to the complexity of work (fast decision making, working under time pressure, responsibility in conducting maneuvers with vital implications, neuropsycho-sensory constraints (auditory, visual, psycho-emotional (tab. I).

TABLE I

Constraints resulting from work complexity

Constraints	Group I (n=50)	Group II (n=50)	p Value
Fast decisions and work under time pressure	46	10	< 0.001
High responsibility	48	12	< 0.001
Emotional nature	19	27	>0.05
Marked by events	38	19	< 0.001
Occupational stress	46	39	0.02

Interpretation: Significantly increased exposure ($p<0.001$) of the ambulance service staff compared to education personnel in terms of work complexity.

Occupational stress is recognized by most employees, the difference in perceived occupational stress being insignificant between the two groups ($p = 0.002$).

Interpretation: Significantly increased exposure ($p<0.001$) of ambulance staff compared to education personnel for noise levels over 87 dB, ambiental noise, low temperature, humidity and air currents (tab. II).

Interpretation: Significantly increased exposure ($p<0.001$) of ambulance staff in comparison to the education personnel regarding walking on uneven/inclined ground, carrying weights exceeding the prescribed limits (stretcher bearers often carrying obese patients), maneuvers overexerting the cervical spine that require keeping the head and neck in a fixed position; vicious postures (anterior trunk flexion, nonphysiological angulations, squatting position during resuscitation) that overexert the dorsolumbar spine (2, 3).

For the education staff, exposure is sig-

nificantly higher (p<0.001) in case of extended arm positions (keeping the arms raised) required for writing on the blackboard (table III).

TABLE II

Work environment-related risk factors

Risk factors	Group I (n=50)	Group II (n=50)	p Value
Noise > 87 dB	47	11	< 0.001
Ambiental noise	47	6	< 0.001
High temperature	32	29	>0.05
Low temperature	40	24	< 0.001
Humidity	40	9	< 0.001
Air currents	47	8	< 0.001

TABLE III

Work organization-related risk factors

Risk factors	Group I (n=50)	Group II (n=50)	p value	Odd ratio (OR)	Confidence interval (CI 95%)
Orthostatism	36	41	>0.05		
Wearing weights	39	5	< 0.001	16.53	4.31-62.5
Vicious postures	47	15	< 0.001	9.06	2.65-30.95
Walking on uneven, inclined ground	45	11	< 0.001		
Overload of neck, lumbar spine and peri-scapular-humeral joint	41	10	< 0.001		
Keeping arms in the air	10	39	< 0.001	6.75	2.04-22.25

Interpretation: Markedly high frequency (p <0.001) in group I of the damage to cervical spine, neck and dorsolumbar spine and significantly high frequency (p <0.05) of hearing problems and skin lesions (due to latex gloves, antiseptics); in group II there was a significantly increased frequency (p<0.001) of the symptoms characteristic to vocal strain (dysphonia/hoarseness, irritative cough) (table IV).

TABLE IV

Symptoms resulting from exposure to risk factors in the two occupational groups

Symptoms	Group I (n=50)	Group II (n=50)	p Value
Neck and cervical spine pain	41	10	< 0.001
Low back pain	47	37	< 0.001
Hearing problems	29	17	< 0.008
Dry, itching skin	33	21	< 0.008
Tired eyes	43	39	< 0.12
Visual disturbances	39	42	< 0.12
Dysphonia, irritative cough	5	27	< 0.001

As to work security, 50% of the ambulance service respondents assert that the minimum endowment and work safety and health requirements are met compared to 60% of the teaching staff who believe this is formal and theoretical.

CONCLUSIONS

Of all respondents, 94% in group I and 84% in group II stated that there are occupational hazards at the workplace. The occupational particularities of the public ambulance service reflected in specific risk factors had a statistically significant increased relevance for musculoskeletal pathology.

The identification of risk factors is part of an extensive technical-administrative and educational prevention program; occupational safety and health training for workers must aim to prevent the specific hazards and risks.

EXERCISE AND SLEEP A BIDIRECTIONAL RELATIONSHIP

Numerous studies conducted with individuals without sleep disorders have shown that exercise improves sleep quality but only a few studies evaluates relationships between exercise and sleep in people with sleep disturbances. In a study included women with insomnia, Baron and colleges were demonstrated that exercise improved total sleep time, sleep efficiency and sleep quality but the exercise during the day improved not the sleep on same night. Furthermore, lack of sleep decreased willingness to exercise. The bidirectional relationship between exercise and sleep showed that regular long-term exercise is a healthier way to improve sleep and encourage exercise participation. (Baron KG; Reid KJ; Zee PC. Exercise to improve sleep in insomnia: exploration of the bidirectional effects. *J Clin Sleep Med* 2013; 9(8): 819-824).

AN INDIRECT EVALUATION OF THE NATIONAL PROGRAM OF DIABETES MELLITUS– STUDY CASE OF ROMANIA (Abstract)Diabetes mellitus (DM) represents an important problem of public health according to the worldwide statistical data. In Romania, the national program is facing the same situation: increasing incidence (both for children and adults) and prevalence of this disease. **Aim:** To evaluate the results of the national program for DM through some indirect indicators. **Material and methods:** This study represents a descriptive analysis of hospitalized DM cases between 1.01.2009 and 31.03.2013, in Romania. The lack of statistical data available from the Ministry of Public Health (the latest update on the web page for DM is from 2007) makes the evaluation of the outcomes of this program quite difficult. An indirect evaluation is possible using the national hospital registrations for DM complications, recorded by the National School of Management and Public Health. For diagnostic registration was used the classification for Diagnostic Related Group (DRG), version HCFA DRG v. 18.**Results:** Despite the facilities offered to diabetic patients through the program, the burden of DM over the health system is quite large due to the large number of patients having complications. **Conclusions:** Even the objectives of the program appear to be accomplished; the indirect outcomes of the evaluation suggest that could be a gap between the hospital specialist and family doctors and a lack of health education for patients with DM. **Keywords:** DIABETES MELLITUS, NATIONAL PROGRAM, EVALUATION, HOSPITAL, FAMILY DOCTOR.

Diabetes mellitus (DM) represents an important problem of public health according to the worldwide statistical data, the World Health Organization (WHO) describing this as the chronic disease epidemic of this century.

According to Diabetes Commission from Ministry of Public Health, in Romania are actually registered 800,000 diabetic patients, more than 600,000 having neuropathy due to the disease. Incidence and prevalence of diabetes mellitus (DM) are increasing in Europe and, as well, in Romania. The 5th edition of IDF Diabetes Atlas estimates that the prevalence rate in 2011 was 9.2% of the adult population (almost 1,506,300 people) and will rise up to 11.1% in 2030 (1). The latest WHO data published in April 2011 shows that DM deaths in Romania reached 2,203 or 1.02% of total deaths. The age adjusted death rate is 6.29 per 100,000 of population, ranking

Romania on the 179th place in the world (2). The incidence of childhood onset type 1 diabetes is increasing in many countries in the world, with geographic differences in trends within Europe with an overall annual increase estimated around 3%. There is also good evidence to suggest that, in relative terms, increases are greatest in young children (1).

The treatment for diabetic patients is free of charge, due to the National program for DM. According to the latest legislation, the cost for the treatment will be supported by the Insurance Houses at the national and local levels. The national health programs represent, according to Health Reform Law no. 95/2006, a set of multi-annual actions, in order to evaluate, prevent, treat and control the diseases having a population' health status major impact (3). The program for DM is one of them. The aim of this program is to improve the health status of diabetic patients and to increase life span through the access to specific treatment.

The objectives are as follows: prevention and control for diabetes and other nutrition diseases; treatment with insulin for diabetic patients; treatment with oral antihyperglycemic agents. The activities included are referring at: information, education, communication and training for the personnel involved in the program; periodically and annually evaluation for damage blood vessels and glycosylated hemoglobin HbA1c; insuring the self-monitoring for insulin-treated patients; facilitating the access to some special treatments, such as insulin pumps or special shoes, in certain cases; implementing the National Register for Diabetes.

The coordination of the program is ensured by the General department for policies, strategies and health quality management. The Institute for Diabetes, Nutrition and Metabolic Diseases (located in Bucharest) is responsible for technical coordination.

MATERIAL AND METHODS

The evaluation of the DM national health program results through some indirect indicators is a descriptive analysis of hospitalized DM cases between 1.01.2009 and 31.03.2013 in Romania. The lack of statistical data available from the Ministry of Public Health (the latest update on the web page for DM is from 2007) makes the evaluation of the outcomes of this program quite difficult. An indirect evaluation is possible using the hospital registrations for DM complications, recorded by the National School of Management and Public Health, with some certain limitations. The records are referring to the hospitals indicators using the classification for Diagnostic Related Group (DRG), the United States version HCFA DRG v. 18. The limitations of the study are referring to some aspects: these counts may include multiple hospitalizations by the same individuals, which are usually for patients with diabetes; the unavailability of data for hospitalization costs; we cannot separate the cases between type 1 and type 2 diabetes or by age-groups (4).

RESULTS

Despite the facilities assured through the national health program, the burden of DM over the health system is quite heavy due to the large number of patients having complications. The hospitals are facing with problems of acute episodes of DM, which is a chronically condition. According to the database of The National School of Public Health and Management, the number of diabetic cases with severe complications and co-morbidities (CC) is increasing

between 2010 and 2012. The cases without severe CC are slightly decreasing during 2009 - 2012. The total amount of days in hospitals is more than one million between 01.01.2009 and 31.03.2013 for 185,260 cases (tab. I).

TABLE I

Number of hospitalized diabetic cases by year, type of complications, and number of days in hospital

Year	Diagnostic	No. of cases	Days in hospital
2009	Diabetes with severe CC	0	0
	Diabetes without severe CC	24,161	152,282
	Diabetic foot	0	0
2010	Diabetes with severe CC	23,413	160,571
	Diabetes without severe CC	21,440	133,383
	Diabetic foot	1,919	21,652
2011	Diabetes with severe CC	24,678	165,390
	Diabetes without severe CC	19,957	122,675
	Diabetic foot	1,878	21,099
2012	Diabetes with severe CC	26,145	175,229
	Diabetes without severe CC	15,522	95,082
	Diabetic foot	2,142	23,086
2013- first trim.	Diabetes with severe CC	7,178	47,648
	Diabetes without severe CC	4,353	25,719
	Diabetic foot	0	0
Total			1,143,816

TABLE II

Number of hospitalized diabetic cases by year, and type of care

Year	Diagnostic	No. of cases in acute care units	No. of cases in chronic care units
2009	Diabetes with severe CC	0	0
	Diabetes without severe CC	23,453	726
	Diabetic foot	0	0
2010	Diabetes with severe CC	22,666	747
	Diabetes without severe CC	20,562	878
	Diabetic foot	1,919	0
2011	Diabetes with severe CC	23,920	758
	Diabetes without severe CC	19,109	848
	Diabetic foot	1,878	0
2012	Diabetes with severe CC	25,396	749
	Diabetes without severe CC	14,671	851
	Diabetic foot	2,141	1
2013- first trim.	Diabetes with severe CC	23,920	758
	Diabetes without severe CC	0	0
	Diabetic foot	0	0

The inpatients with complications were hospitalized in acute care units or chronic care units. It is evident that patients, or more correctly, the number of cases receiving health care for DM acute episodes are far greater than those receiving health care in chronic units: in average, 32 acute episodes to 1 in chronic care units (tab. II).

The average length of stay (ALOS) is varying due to complications and type of received care (acute or chronic) (tab. III).

TABLE III.

Average length of stay for diabetic cases by year, and type of care

Year	Diagnostic	Acute care ALOS (days)	Chronic care ALOS (days)
2009	Diabetes with severe CC	0	0
	Diabetes without severe CC	6.15	11.30
	Diabetic foot	0	0
2010	Diabetes with severe CC	6.69	12.00
	Diabetes without severe CC	5.98	11.88
	Diabetic foot	11.28	0
2011	Diabetes with severe CC	6.54	11.80
	Diabetes without severe CC	5.91	11.53
	Diabetic foot	11.23	0
2012	Diabetes with severe CC	6.69	12.00
	Diabetes without severe CC	5.98	11.88
	Diabetic foot	10.78	15.00
2013- first trim.	Diabetes with severe CC	6.54	11.80
	Diabetes without severe CC	0	0
	Diabetic foot	0	0

DISCUSSION

Despite the facilities offered by the national health program, the hospital burden due to DM is large. In Romania, funds allocated in 2010 to the National Program for Diabetes and other Metabolic Diseases amount to approximately EUR 57,731,000, representing 1.47% of total health expenditure (5). The amount of money is directly increasing with the age of the diabetic patient, because the duration of diabetes is the main factor determining complications prevalence, the most important factor associated with an increased risk of complications being the glycemic control (5, 6). The ALOS is higher than other values registered in other countries. For example, in US, in 2004, the mean length of stay for hospitalizations among patients with diabetes was 5.5 days, which was one day longer compared to non-diabetes stays (7). According to Centers for Disease Control and Prevention, the value for ALOS of hospital discharge with diabetes as first-listed diagnosis decreased from 8.2 days in 1988 to 5.0 days in 2009 (8). In Singapore, admission for diabetes with complications varies within the limits 4.9 to 10.1 days (9).

This study reveals some of the indirect outcomes of the national program for diabetes, these indicators having more possible explanations. The level of socio-economic development of Romania could be one of them. The treatment for the DM

is not only a medical one. It implies, as a first step, a changing in life style, a dietary regimen. These changes require special attention, considerable expenses, and psychological efforts from patients and their families. The lack of money could be, for many patients, an obstacle to keep the blood sugar under control, so most of them are not able to have a proper diet. On the other hand, many diabetic patients consider that the medical doctor specialist in diabetes is the only „in charge" with their health condition. Or it is known that DM, as the other chronic diseases, requires ongoing adjustments by the affected person and interactions with the health care system (10). So we want to underline the importance of family doctor, who is not, unfortunately, part of this equation in many cases. His role is to help patients to achieve the self-management of the diabetes.

CONCLUSIONS

Even all people have access to periodic checkups for diabetes carried out by specialists, and injectable insulin and pens, insulin pumps and accessories, blood glucose monitoring strips and meters, lipid testing, retinopathy screening are fully reimbursed, the indirect evaluation of the National health program for DM indicated some deficiencies not at the central level, but at the local one. There is a lack of care coordination between specialist in hospital / ambulatory units and family doctors, the last ones being the most indicated to follow-up continuously the diabetic patients. As a consequence, patients are inadequately trained to manage their illnesses in the specific socio-economic conditions of their life.

DEMODEX: COMMENSAL OR PATHOGEN?

Aida Corina Badescu[1], Luminita Smaranda Iancu[1], Laura Statescu[2]
University of Medicine and Pharmacy "Gr. T. Popa" – Iasi
Faculty of Medicine

2. Discipline of Dermatology

DEMODEX: COMMENSAL OR PATHOGEN? (Abstract): *Demodex* mites are considered commensals of human pilosebaceous units. Their role in skin disease is controversial. The **aim** of our study was to investigate the *Demodex* infection in patients with characteristic skin lesions and to correlate the level of infestation with epidemiological and clinical features. **Material and methods**: we have studied 120 symptomatic patients, diagnosed between January 2012 and December 2012; the detection of mites was realized by microscopic examination of potassium hydroxide preparations from biological samples taken by scraping and squeezing method**. Results**: The total prevalence rate of infection in our study group was 40.83%. We did not find statistical significant correlation with gender or age or with the type of lesions. **Conclusions**: Prevalence of *Demodex* infestation in facial dermatitis is high and its detection must be taken into consideration in routine diagnostic of facial suggestive lesions. Keywords: *DEMODEX*, FACIAL DERMATITIS, RISK FACTORS.

The microorganism was first reported in 1842 by Gustav Simon, after the microscopic examination of the sebaceous content of acne vulgaris lesions. He describes "an animal" with head, legs and body (1). The adult parasite has a worm-like appearance, the body consisting of cephalothorax and abdomen. The cephalothorax has fine lines, irregularly distributed, while the abdomen has horizontal, visible lines.

According to current taxonomy, *Demodex* is a genus of parasitic *mites* belonging to the family *Demodicidae*, superfamily *Cheyletoidea*, subclass *Acar*i, phylum *Arthropoda.* Demodex species found on humans are *Demodex folliculorum* and *Demodex brevis*, *D. folliculorum* species being the most common.

Although it was discovered and described over 170 years ago, its role in pathogenesis remains unclear. It is considered by many scientists as a commensal microorganism that inhabits the sebaceous follicle and the normal hair follicles. Although this mite can be found all over the skin, it prevails on the face, especially in areas with a high density of sebaceous follicles such as nasal wings, nasogenian groove, cheeks, forehead or chin. *D. folliculorum* can be found in hair follicles as well as sebaceous ducts and meibomian glands, while *D. brevis* was only detected in the deep part of sebaceous follicles (1).

Other researchers consider it an obligate parasite. *Demodex* is believed to be a risk factor associated with lesions of acne rosacea (2, 3, 4), seborrheic dermatitis, perioral dermatitis, pigmentations, blepharitis

(5,6) and even with sebaceous adenoma lesions (7) or epithelioma (8). Some studies report a higher frequency in patients with diabetes or severe immune deficiency (9).

At the moment, it is considered that transition from comensalism to parasitism is related to alterations in host immune response. The increase in the number of parasites (more than 5 mites/field or more than 5 mites/cm^2 of skin surface or skin biopsy) or their intradermal penetration is accompanied by nonspecific inflammatory and immune responses that lead to irritation and various skin lesions. Demodicidosis is a term that defines the skin lesions secondary to *Demodex* infestation.

The mode of transmission is direct, usually by close contact between individuals. Regarding the moment of contamination, it is considered to be an early acquisition, children being infected relatively quickly after birth, through direct contact with their carers. Some studies report a high infection rate, of over 90% in student communities (10). Another study reported a contamination level of 37% in asymptomatic persons handling biological waste and in health workers (11). Other studies show significant associations between *Demodex* infestation and gender, certain occupations, but especially with age (10, 11).

In terms of treatment, there is no standard regimen. Therapeutic options include topical medication (there is documented effectiveness for permethrin, crotamiton, lindane, salicylic acid, retinoids, metronidazole) as well as systemic therapy (currently used agents are retinoids, ivermectin and metronidazole) (1).

MATERIAL AND METHODS

We conducted a descriptive, retrospective study on a group of 120 patients, diagnosed between January 2012 and December 2012 with various facial skin lesions. Detection of *Demodex* was performed in patients with facial dermatitis for which the parasite is considered a risk factor (rosacea, seborrheic dermatitis, acne vulgaris). Suggestive lesions from which the samples were taken were papular, papulopustular or granulomatous lesions, predominantly localized on the face, forehead and scalp. Investigations were performed in a private medical laboratory on five dermatologists' recommendation. The control group consisted of 20 asymptomatic individuals from the same age group as those in the study group.

Facial sampling for the detection of *Demodex spp* can be done by manual extraction (squeezing method) or with the extractor of comedones and pustular lesions. In the case of squamous lesions, samples can be taken by scraping method. Cellophane tape method (CTM) is recommended for the asymptomatic parasite detection (10). In our study harvesting was done by the same laboratory doctor. We used extraction for follicular lesions and scraping for squamous lesions. For asymptomatic control group we used CTM.

Wet mount preparations with 20% KOH were examined under a microscope with 10X and 40X objectives. The number of parasites was semi quantitatively assessed. We considered the presence of 1 parasites/sample or mite fragments as low contamination and a number of more than 5 parasites as an important contamination (fig. 1).

We analyzed the prevalence of infection in symptomatic patients from the study group compared with asymptomatic controls. We searched for correlations between infestation and age or gender of patients, type of clinical lesions and sample.

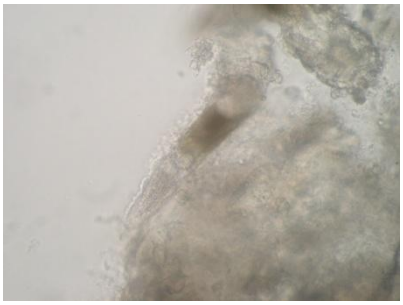

Fig.1. *Demodex folliculorum* (wet mount preparation with KOH, 100X magnification).

Data were examined with Epi Info program. Statistical analysis was performed by t-Student test. A value of $p < 0.05$ was considered significant.

Informed consent was obtained for each patient enrolled in the study.

RESULTS

In our study group, the total prevalence rate of *Demodex spp* infection was 40.83% (49/120). In the control group the prevalence of infection was 15%. We found a significant association between infestation and the presence of skin lesions ($p = 0,026$) (tab. I).

TABLE I

Epidemiological and clinical characteristics of the group with demodicidosis

Investigated characteristics	**Number of patients (ratio)**		
Prevalence	Positive *Demodex* detection	49(40.83)	
	Negative	71(59.16)	
	Total 120		
Gender	Males	18(36,73)	
	Females	31(63.26)	
	Total - 49		
Age group	<30	Males	6(42.85)
		Females	8(57.14)
		Total - 14	
	31-45	Males	8(36.36)
		Females	14(63.63)
		Total - 22	
	>46	Males	4(30.76)
		Females	9(69.23)
		Total - 13	
Lesions type	Rosaceea-like lesions	20(40.81)	
	Seborrheic lesions	15(30.61)	
	Acneform lesions	14(28.57)	
Sample type	Facial flakiness	28(57.14)	
	Scalp flakiness	5(10.20)

	2 - 4	35(71.42)	
	>5	5(10.20)	

The individuals enrolled in our study were aged between 19 and 85 years. Prevalence of infestation was 33.33% for the age group under 30 years, 42.30% in age group 31-45 years and 52.00% in the group with age over 46 years. There is an increased level of infestation in patients with advanced age but no statistically significant correlation was found, probably due to the small number of patients in the study group.

Regarding the type of clinical lesions or the type of sample taken, there are not statistically significant differences between groups.

All patients were infected with *D. folliculorum* species. In one patient, we found microscopic features suggestive for the *D. brevis* species.

DISCUSSION

This is the first study performed to Romanian patients related to the prevalence of *Demodex* infection in patients with facial skin lesions. There are only two articles published in Rev Med Chir journal, reporting two clinical cases of *Demodex* dermatitis, late in the 1960' (12).

In our study we found a significant association of infestation in symptomatic patients compared with the control group. Parasitism rate between the control and study group is similar to that from previously published data, typically up to 12% of the population showing contamination of follicles with *D. folliculorum* (13). Studies on larger groups indicate values between 20 and 80% (10, 11). Large differences are closely related to the study group selection criteria and especially to the method of sampling.

Gender ratio (male/female) was 1/1.7 but the prevalence rate is higher in males (47.36%) than females (37.80%); however, this difference was not statistically significant. Usually, infestation is stronger in men than in women and in younger populations than in adults, probably due to different distribution of seborrheic glands. Others studies report a growth rate of parasitism level with age (11), but there are studies that show a relatively uniform distribution of cases in the three age groups considered (1).

While most scientists agree that there is a tendency to develop skin lesions with age, especially in men, but that was not the case in our study. This is probably due to reduced addressability to the dermatologist of male patients, regardless of age, perhaps due to different mentality in our country.

Significant association of mites with different facial dermatitis are described in many studies (2, 3, 4, 10, 11). We did not find significant differences in relation to the type of lesion or sample type, probably because of the small number of samples examined. The most common association is described in published clinical trials with papulopustular lesions rosacea, and perioral dermatitis lesions and the degree of parasitisation is directly related to the frequency and dosage of corticosteroids used (13).

Regarding the intensity of infestation we did not find any statistically significant differences related to age or type of biological samples. Number of parasites detected/sample is lower when compared to data from other studies and this is very likely influenced by sampling technique used. We mainly used the extraction and scrapping techniques but studies revealed that the most effective detection is made by surface biopsy, a relatively laborious technique described by Klingman, but difficult to put in clinical in practice (14).

CONCLUSIONS

Demodex mite is a commensal that can become pathogenic under certain conditions. Demodicidosis lesions are highly polymorphic, differential diagnosis is sometimes difficult when relying solely on clinical appearance. Laboratory diagnosis is relatively easy and rapid but given the high rate of infection in asymptomatic subjects, it is very important to monitor not only the presence of parasite and their evolution, especially in high patients group. The prevalence in the study group was high (40.83% respectively), and future studies are necessary to improve the rate of positive diagnosis, using different methods of sampling on larger groups of patients The quantitative detection can be correlated with other risk factors that can cause an immune response from the host and can ultimately lead to development of lesions. In any case, commensal or pathogenic, *Demodex* must be taken in consideration and its detection should be a routine investigation for patients with facial dermatitis.

COLON CANCER AT MOLECULAR LEVEL - USEFULNESS OF EPITHELIAL- MESENCHYMAL TRANSITION ANALYSIS (Abstract): Colorectal cancer (CRC) is the third form of cancer in both men and women. In Romania, the incidence of CRC in 2000 is 17.74 ‰, in 2002 becoming the second cause of death. We reviewed a series of studies that are related to colon cancer and studied the epithelial-mesenchymal transition at the front of tumor invasion (EMT). Cellular phenotypic changes characteristic of EMT can be induced by the absence of transition cofactor (p300) involved in cellular regulation. Loss of syndecan-1 marker is associated with local tumor stage and metastasis. Modulators of protein kinase resistance was associated with changes in genes involved in EMT (including vimentin hyperexpression) and genes involved in invasion (N-cadherin) with a decrease expression of genes involved in epithelial cell adhesion (E-cadherin). Progression in colon cancer is characterized by activating mutations in Ras genes and tumor growth factor action. Vimentin expression associated with EMT initiates molecular program. One of the characteristics of EMT is the loss of E-cadherin. TGF-β (transforming growth factor beta) induces epithelial-mesenchymal transition in colon cancer cell lines with the microsatellite stability, inducing cell invasion and migration. EMT is a critical early event involved in invasion and metastasis of colorectal cancer, characterized by the presence of markers specific to each phenotype, epithelial or mesenchymal. Multiple biomarkers involved in the induction of EMT may represent future therapeutic target in the treatment of colonic neoplasia. **Keywords:** COLON CANCER, EPITHELIAL-MESENCHYMAL TRANSITION, BIOMARKERS

Colorectal cancer (CRC) is the third most frequent cancer in women, after breast and uterine cancers, and in men after lung and stomach cancers. In 2006 there were 412,900 new cases of colorectal cancer in Europe, accounting for 12.9% of all cancers. Colorectal cancer was responsible for 217,400 deaths in Europe in 2006. This accounts for 12.2% of all death from cancer (1). In Romania, the frequency of CRC is increasing rapidly, with a twofold increase in incidence and mortality in the last 20 years. Our country belongs to the countries with a mean CRC incidence due to the yearly incidence of 17.74 ‰ reached in 2000. In 2002, CRC became the second leading cause of death after lung cancer, exceeding gastric cancer by 4150 deaths (19.05 ‰ inhabitants) (2).

Epithelial-mesenchymal transition (EMT)

is supposed to be an event in carcinogenesis in general. Through EMT, epithelial tumor cells can achieve transdifferentiation ability in myofibroblasts which lose their malignant phenotype but constitute the desmoplastic stroma essential for tumor growth, invasion, and metastasis, thus providing tumor cells an additional survival advantage. By defining the morpho-functional aspects of epithelial-mesenchymal transition in colon neoplasms, the identification of some of their relationships with a number of prognostic markers becomes possible. Colon cancer diagnosis requires histopathological confirmation, and thus a protocol for interpreting EMT as a component of tumor microenvironment with impact on prognosis and therapeutic choices could be recommended. Clonal expansion and acquisition of tumor cells malignant characteristics is favored by the presence of microenvironment, very often ignored (3).

Epithelial-mesenchymal transition is characterized by loss of epithelial markers simultaneously with the acquisition of mesenchymal components. E-cadherin is low while N-cadherin, vimentin, fibronectin are increased. E-cadherin is an epithelial marker that plays an important role in maintaining epithelial integrity. Vimentin is a marker for detecting epithelial transition and acquisition of fibroblastoid-like phenotype (13).

Literature review by accessing several databases and selecting the studies on colon cancer and the phenomenon studied at the level of tumor invasion front represented by EMT

DISCUSSION

In literature there are numerous studies on epithelial-mesenchymal transition (EMT) aimed at identifying markers that characterize this phenomenon. Colon cancer has been classically described by its clinicopathological features that allow prognosis to be predicted only after surgical resection and staging. A study by Loboda demonstrated that EMT is the dominant phenomenon in colon cancer. Microenvironment analysis in a series of 326 patients with colon cancer has identified the first main component (PC1) of the most variable set of genes through which adhesion and extracellular matrix were significantly affected. Also, it revealed that cell line derived EMT is significantly associated with PC1 gene expression. Expression of this gene was able to differentiate favorable from poor prognosis and was strongly correlated with recurrence and disease progression even in intermediate stages II and III. It was also correlated with neoplasm progression and the poorly differentiated nature of the disease. PC1 had a role in predicting metastasis-free interval to the onset of metastases and recurrence. PC1 gene expression and epithelial versus mesenchymal differentiation may be useful in the characterization of cell lines. Understanding which cell lines best represent the epithelial versus mesenchymal phenotype will be useful in determining the best models for subsequent treatment and will allow tumor description with the help of cell lines (4).

EMT characteristic cell phenotypic changes can be induced by the absence of a transition cofactor (p300) involved in regulating many cellular processes. In a study in which the absence of p300 was induced it was noticed that cells with this deficiency have a phenotype corresponding to an aggressive cancer, with loss of intercellular adhesion and cell-matrix adhesion defects. Beta-cadherin was found to increase p300 nuclear fraction that might contribute to EMT inducing intercellular signals (5).

Another studied factor was LIM protein 2 (Four-and-a-half LIM protein 2 - FHL2). This protein acts as a mediator that induces EMT. Expression profile of FHL2 in normal cells and colon cancer was inversely correlated with the expression profile of E-cadherin. FHL2 was expressed only by cancer cells and E-cadherin was expressed predominantly by normal epithelial cells. This marker was expressed both by primary and metastatic colon cancer cells. FHL2 can be regarded as a marker of progression and an important therapeutic target in colon cancer (6).

In colorectal adenocarcinomas, loss of syndecan-1 marker is associated with tumor stage and local metastasis. Syndecan-1 is a transmembrane proteoglycan with important roles in intercellular adhesion and cell adhesion to extracellular matrix, and acts as a growth factor co-receptor. In a study analyzing the expression of this biomarker in the basement membrane it was found that the presence of syndecan-1 correlated with advanced stage and lymph node metastases, which is more common in men ($p = 0.042$), but was not associated with age and tumor location (7).

Protein kinase Cs (PKC) plays an essential role in signal translation at cell level (8). It includes at least 12 isoforms with variations in tissue expression, with substrate specificity and cell locations related to cell function: cell differentiation, proliferation, apoptosis, motility, adhesion, invasion and metastasis (9). Resistance to PKC modulators was associated with changes in the genes involved in EMT (including vimentin overexpression) and genes involved in invasion (N-cadherin), together with decreased expression of messenger RNA (mRNA) by several genes involved in epithelial cell adhesion (E-cadherin), all involved in cancer progression (10).

Colon cancer progression is characterized by the activation of mutations in Ras genes and response of tumor growth factor (transforming growth factor-β-TGF-β). Ras and TGF-β act synergetically and increase expression and stability of messanger RNA for vascular endothelial growth factor (VEGF), an angiogenesis regulator both in intestinal epithelial cells (iRAS) and in cell culture models. TGF-β has been shown to have both a role of tumor suppressor and tumor promoter (11). Oncogenic Ras and TGF-β acting synergistically regulate genes at posttranscription level, mechanism involved in cell transformation and tumor progression of colorectal cancers (12).

To analyze cell phenotype in colorectal cancer and their invasive capacity, a study was conducted to assess the importance of reducing the expression of PTEN (Phosphatase and tensin homolog deleted on chromosome ten) coupled with TNF-α response. The result revealed cell changes consisting in EMT and increased invasive capacity of colorectal cancer cell. It was found that PTEN inhibition associated with tumor microenvironment factors favor the invasive phenotype with invasion and metastasis role in colorectal cancer (13).

Neuropilins (NRPs) are transmembrane non tyrosine-kinase glycoproteins normally described in the nervous system. Recently new roles of NRPs involved in oncogenesis have been identified. Besides their association with tumor vessels, NRPs were expressed in a variety of tumors, suggesting that they have an important role in cancer progression. A study has shown that neuropilin-2 confers a fibroblast-like phenotype to cancer cells, suggesting that it is involved in epithelial-mesenchymal transition. The presence of neuropilin-2 in colorec-

tal carcinomas was correlated with loss of such epithelial markers as cytokeratin-20 and E-cadherin and acquisition of some mesenchymal molecules such as vimentin (14).

In a study analyzing the phenotype of colon adenocarcinoma cells it has been shown that BRAF and RAS oncogenes (Ras homolog gene family) provide properties that intervene in neoplastic migration and invasion conferring cells a more aggressive phenotype (15).

Blood vessel epicardial substance (BVES) was analyzed in a study that found that its expression is suppressed in all stages of colorectal carcinoma and adenomatous polyps, indicating that inhibition occurs in the rapid stages of malignant transformation. BVES in CRC cell lines induces an epithelial phenotype, reducing proliferation, migration, and invasion. Thus, BVES determines EMT, and its suppression may be an important step in colonic carcinogenesis (16). Epithelial-mesenchymal transition is also present in such pathological processes as parietal tumor progression. Colorectal cancer tumor cells at the invasion front have mesenchymal features characterized by hypermigratory capacity, poor differentiation, and are hyperproliferative and unable to establish intercellular connections (15).

Expression of vimentin, a classical mesenchymal marker present in tumor cells of colonic epithelium initiates the molecular program associated with EMT. One of the features of EMT is the loss of E-cadherin. In a study that analyzed the expression level of the two molecules it was found that E-cadherin was significantly lower in regions where vimentin was strongly expressed, whereas vimentin could be barely detected in most regions which maintained an increased E-cadherin expression. This mutual pattern was noticed in all examined tumors, although only a few cancer cells maintained a moderate expression of both genes. These results further support the idea that some neoplastic cells of early intestinal adenomas initiate the epithelial-mesenchymal transition (17).

Another study conducted at the Masachusett General Hospital Boston aimed to determining whether dysfunctional signaling of transforming growth factor-beta (TGF-β) impairs the induction of EMT, the functional and morphological effects of TGF-β on microsatellite stability and instability in colon cancer cells was examined. Two groups of patients with colon cancer, one with microsatellite stability and the other with microsatellite instability identified at the cell level were analyzed retrospectively from 2001 to 2008. Study results showed that TGF-β induces epithelial-mesenchymal transition in colon cancer in the cell lines with the microsatellite stability. In the same cell lines, TGF-β induces cell invasiveness and migration (18).

Tumor-host interactions at the invasion front in colorectal cancer represent a critical interface occurs where tumor progression and tumor cell dissemination occur. Evidence suggests that the presence of infiltrating growth pattern is inversely correlated with the presence of immune or inflammatory responses at the invasive tumor front. On the one hand, the infiltrating tumor border promotes progression and dissemination of tumor cells by lymphatic and vascular vessels penetration. On the other hand, the host attempts to reject this attack by mounting an immune response, especially cytotoxic T lymphocytes to protect lymphatic and vascular channels from tumor invasion. Several tumor associated antigens, such as CD3, CD4, CD8, CD20 and other types of inflammatory cells, were

identified as potential prognostic factors. Together they suggest that the balance between pro- and anti-tumor factors (immune response and various types' inflammatory cells) at the invasive front in colon cancer may be critical in tumor progression and clinical outcome in patients with colon cancer (19).

CONCLUSIONS

The molecular mechanisms leading to malignant transformation and metastasis in colon cancer are incompletely understood. Knowledge of these mechanisms is of great importance if we hope to treat patients who seek a reduction in cancer-related mortality. Epithelial-mesenchymal transition is a critical early events involved in the invasion and metastasis of colorectal cancer, characterized by the presence of markers specific to each phenotype, epithelial or mesenchymal. The multiple identified markers, with a role in EMT induction, may be subsequent therapeutic targets in the treatment of colonic neoplasm.

SERUM HIGH-DENSITY LIPOPROTEIN CHOLESTEROL LEVELS - PROGNOSTIC FACTOR IN GASTRIC CANCER

Gastric cancer is an important cause of morbidity and mortality. The 5-year survival rate after complete gastrectomy for gastric cancer is approximately 60% and the rate of recurrence after surgery is 30%. Low levels of high-density lipoprotein cholesterol (HDL-C) are associated with a higher risk for gastrointestinal tract cancers. A retrospective study by Tamura and colleagues examined the association between preoperative serum HDL-C levels and gastric cancer. They compared patients with normal levels of HDL-C with patients with low levels of HDL-C, for 5 years after the surgery. Results showed that the lymphatic and vascular invasion was significantly increased in the low HDL-C group. The patients in the normal HDL-C group had a significantly better prognosis than those in the low HDL-C group, which presented an increased rate of mortality from gastric cancer. In conclusion preoperative serum HDL-C level may be a clinical prognostic factor for gastric cancer patients (Takafumi Tamura, Satoshi Inagawa, Katsuji Hisakura et al. Evaluation of serum high-density lipoprotein cholesterol levels as a prognostic factor in gastric cancer patients. *J Gastroenterol Hepatol*. 2012; 27:1635-1640).

THE ROLE OF STATINS IN DEEP VEIN THROMBOSIS (Abstract): Deep vein thrombosis (DVT) represents the formation of a blood clot in one of the deep veins of our body, predominantly occurring in the legs. According to international guidelines, the goal of the treatment in deep vein thrombosis is to prevent the progression and the recurrences of thrombotic process. The aim of this article is to explain the pathogenetic mechanism of deep vein thrombosis and the benefits of statins in such a disease. The vasoprotective effects of statins are related to their anti-thrombotic and anti-inflammatory properties. The administration of statins is associated with a lower incidence of venous thromboembolism (VTE) in the general population. It also helps in reducing the frequency of recurrences, being prescribed after an optimal 6 to12 month anticoagulation. The study of these properties creates new opportunities for the use of statins in the prevention of post-thrombotic syndrome and recurrent venous thromboembolism (VTE).
Key words: STATINS, VENOUS THROMBOSIS, THROMBOEMBOLISM.

About 1 in a 1000 adults develops annually a *Deep Vein Thrombosis* (DVT). The incidence increases from 0.01% in young adults to 1% in people over 60. More than half of these events involve deep vein thrombosis in the inferior vena cava basin. In 25% of untreated cases, the thrombi extend towards proximal veins. Consequently, in the case of proximal DVT the risk of asymptomatic or symptomatic pulmonary thrombo-embolism increases to 5% and that is more likely to occur if the emboli are caused by proximal thrombi. In order to decrease the risk of fatal pulmonary emboli, the early diagnosis and prompt treatment of DVT are essential.

DVT pathogenesis mentions three broad categories of factors also known as Virchow's triad: endothelial injury, venous stasis and hypercoagulability. The vessel wall injury interferes with the coagulation inhibition function and prevents the local fibrinolytic process of the endothelium. Venous stasis, caused by patient immobilization or vein obstruction blocks the clearance and dilution of activated coagulation factors and finally the congenital or acquired thrombophilia, leading to hypercoagulation.

The venous thromboembolism pathogenesis is multifactorial, often resulting from a combination of several risk factors. The most common risk factors for secondary venous thrombosis include cancer,

surgery, immobilization for long periods of time, fractures, paralysis, pregnancy, birth and use of estrogens or of selective estrogen receptor modulators. Still, for approximately 30% of the patients the cause of DVT occurrence remain inexplicable, the same as in the case of spontaneous or idiopathic thrombosis.

THE CORRELATION BETWEEN DEEP VEIN THROMBOSIS AND ATHEROSCLEROSIS PROCESS

The existence of an association between atherosclerosis and idiopathic venous thrombosis was demonstrated for the first time in 2003 by Professor Prandoni and his research group. In a clinical case-control study about half of the patients diagnosed with idiopathic acute venous thrombosis developed signs of asymptomatic atherosclerosis (at least one carotid atherosclerotic plague, estimated by scanning the carotid arteries) (1). The essence of this association is still unknown: could venous thrombosis be induced by atherosclerosis or do the two conditions have a parallel development, in the presence of common risk factors? Certain factors correlated to the development of both pathologies have been identified: old age, obesity, diabetes mellitus, the metabolic syndrome (2). On the one hand the prothrombotic state in atherosclerosis can favor venous thrombotic events. In the case of atherosclerosis (ASVD) the evaluated elements are: the plaque aggregation activation, the blood coagulation activation and the increase of fibrogenesis. All these elements can lead to thrombotic complications both at the arterial level and in the venous system. On the other hand, both clinical conditions can be simultaneously triggered by certain biological stimuli, responsible for the activation of coagulation and swelling in the vascular system. Thus, the excess of fibrinogen, von Willebrand factor antigen, plasminogen tissue activator, D-dimers, coagulation factor VII, C-reactive protein (CRP), tumor necrosis factor- α (TNF-α) and interleukin, that circulate in the blood, cause a procoagulant and pro-inflammatory state both in the venous and the arterial system (3). We cannot exclude the probability that both hypothesis are true, representing thus two pathophysiologic scenarios for the development of venous thrombosis. These hypotheses are confirmed by vast authentic evidence, resulted from important clinical studies. The Cardiovascular Health Study (2009) proved that asymptomatic atherosclerosis represents a risk factor for VTE (venous thromboembolism) (4), while Atherosclerosis Risk in Communities Study (ARIC) showed that that the anti-plaque treatment and/or other antithrombotic treatments plays an important role in the prevention of venous thromboembolism dysfunctions in patients with clinically manifest atherosclerosis (5). Another study assessed the relapse rates for DVT, post-thrombotic damage severity and mortality 10 years after the first VTE episode, in patients previously included in the Duration of Anticoagulation (DURAC) study. After ten years the mortality rate due to acute myocardial infarction (AMI) or fatal *ictus cerebri* was significantly higher (approximately 28%) in patients with spontaneous VTE, if compared with patients with secondary VTE and with the general population (6). Other randomized control trials (P. Becattini; P. Prandoni; N. Bova) demonstrate a higher incidence of symptomatic atherosclerosis (ischemic cardiomyopathy, acute myocardial infarction, cerebral vascular accident, atherosclerosis of the peripheral arteries, ischemic cardiac failure, sudden death) in patients with idio-

pathic venous thrombosis if compared with patients with secondary VTE and with the general population.

THE ROLE OF STATINS IN PRIMARY AND SECONDARY PREVENTION OF VTE (VENOUS THROMBOEMBOLISM)

The objectives of DVT treatment, according to international guidelines, consist in the prevention of the thrombotic process progression as well as the prevention of relapses. Treatment is initiated with unfractionated heparin or low molecular weight heparin, followed by an indirect anticoagulant. The administration of direct anticoagulants will be ceased within 7-10 days while indirect anticoagulants will be administered for at least another six month, if there are no contraindications. The risk of hemorrhage occurrence represents the main criteria in the limitation of oral anticoagulant treatment duration. In most patients, the benefits of long-term prophylactic treatment of recurrent VTE can be compromised by an increased risk of bleeding, especially after 12 months of continuous administration. This fact has consequently demanded the research of alternative strategies for the secondary prevention of VTE, which have recently led to discussions about HMG-CoA reductase inhibitors (7). HMG-CoA reductase inhibitors represent one of the most commonly used groups of drugs. The special attention they are granted is justified not only by their high efficiency as hypolipidemic agents. Numerous experimental in vitro, in vivo and clinical studies have confirmed in the past years several benefic effects resulted through mechanisms that have no connection with the changes in lipid metabolism and are commonly named pleiotropic effects. The vasoprotective effect of statins is ensured by these properties, the anti-thrombotic and anti-inflammatory activity being the most important. These characteristics may lead to new perspectives regarding the post-thrombotic syndrome and VTE recurrences prevention.

The discovery of connections between atherosclerosis and venous thrombosis lead to the initiation of clinical and experimental studies meant to estimate the role of statins in diminishing the VTE risk. A randomized, placebo-controlled, multicenter trial, *Justification for the Use of Statins in Primary Prevention: An Intervention Trial Evaluating Rosuvastatin (JUPITER)*, included 17,800 practically healthy subjects that received 20 mg of rosuvastatinum or placebo, its main purpose being the study of statin efficiency in the decrease of major cardiovascular events rate. The assessment of pulmonary embolism or VTE primary episodes occurrence constituted one of the secondary purposes of the trial (8). After an average surveillance period of 1.9 years (up to a maximum of 5 years) it was concluded that rosuvastatinum administration reduces the symptomatic VTE risk with 43% for the practically healthy subjects participating in the study, when compared to the administration of placebo, no matter if the episode was idiopathic or was caused by a well-known factor.

Specialized literature (9) mentions a series of clinical trials that explore the alternative strategy hypothesis in the VTE prevention and provide scientific evidence of the influence of statins on VTE risk. The multicenter, observational, prospective randomized controlled clinical trial, *Heart and Estrogen/Progestin Replacement Study*, that included 2,763 female subjects provided data that proved a significant decrease of 50% of VTE risk in patients receiving statins. Statins determined a decrease of 22% of the relative risk of DVT

occurrence in patients over 65, in an observational retrospective trial that included a total of 125,000 patients with no history of atherosclerosis, venous thrombosis or cancer (10). Certain authors of case-control clinical trials mention a venous thrombosis risk decrease with approximately 26%-58% following statins therapy (11). In the population-based case-control study (MEGA study) that assessed 10,500 subjects, including 4,500 patients with primary episode of venous thrombosis in the lower limbs or pulmonary embolism, the use of statins, regardless of the active substance or the duration of the treatment, was associated with a significant 55% decrease of primary and recurrent DVT, proving to have a better effect in combination with the main treatment (13). An estimation of the venous thrombotic risk (by means of vascular Doppler) in 2,427 post-menopausal female patients aged between 30 and 89, of which 465 had a first episode of venous thrombosis, showed a significantly lower risk for the subjects who received statins (12). It was at the same time noticed that the risk rate was influenced by simvastatin, regardless of the dose, but remained unchanged in the case of pravastatin administration, probably due to differences in action at the level of coagulation activation internal mechanisms, blocked by lipophilic simvastatin and uninfluenced by hydrophilic pravastatin (13). Another such study assessed 5,824 VTE patients and a control group consisting of 58,000 subjects without a history of venous thrombosis. The outcomes lead to two important conclusions: patients with a history of cardiovascular events are exposed to a certainly higher VTE risk, especially within the first 3 month following an acute myocardial infarction or stroke; constant administration of statins is associated with a lower relative risk of VTE (approximately 26%) (14). The outcomes of a retrospective study that assessed 593 patients with myocardial infarction or ischemic cerebrovascular accident (CVA) showed that statins can be efficient for VTE prevention in atherosclerosis patients, the DVT risk being three times higher in patients who do not receive statin therapy (15). The effect depends on the dosage, being more significant in case of high doses (50% lower risk if compared with the standard 20 mg statin doses).

The use of statins in the case of patients with solid tumors (colon, pancreas, breast, ovarian, renal and cerebral cancer) was associated with a relatively low probability of VTE occurrence (8% as opposed to 21% in the group without statins), including VTE and pulmonary embolism. Regression analysis provided an identical result, regardless of other factors involved, such as smoking habits, the presence of metastases, chemotherapy administration, immobilization, aspirin administration (16). In that particular context, there were some attempts to compare the effect of statins to the effect of fibrates, in a randomized control trial assessing 1,354 patients hospitalized for idiopathic venous thrombosis (17). The use of statins resulted in a significantly lower risk of recurrent VTE episodes, while fibrate administration was associated with a higher risk (0.53 *vs.* 1.88) (18). In another study – the MEGA study – other groups of hypolipemiants (non-statins) caused an increase of 22% in primary or recurrent venous thrombosis risk, compared to patients who did not received hypolipemiant drugs (19). In the above mentioned observational case-control study the female patients were administered statins, fibrates, bile acid sequestrants or niacin; a lower risk of venous thrombosis was signaled only in the group that received statins (20).

The specialized literature does not produce any evidence regarding VTE aggravation or risk increase due to statins therapy. The benefic action of HMG-CoA reductase inhibitors, in the venous thrombosis pathology, is ensured by the anti-plaquetary, anticoagulant, profibrynolitic, anti-inflammatory, anti-cytokine, anti-oxidant and hypolipemiant effects that ensure all of them, the proper functioning of the vascular endothelium and finally contribute to maintaining an optimal balance between pro-thrombotic and fibrinolytic mechanisms. Manifestations of anti-thrombotic effects of statins consist in the inhibition of plaquetary aggregation, a decrease in thrombin production, the blockage of pro-thrombin activation, of the factor V and factor XVIII, the inhibition of the tissue factor with an important part in the maintenance of extrinsic coagulation cascade, the decrease of D-dimers seric level (marker of the prothrombotic state and independent risk factor for VTE recurrences), the stimulation of fibrinolytic activity through the intensification of tissue plasminogen activator (tPA) and the diminishing of plasminogen activator inhibator-1 (PAI-1) (21). Since inflammation is known to be one of the lesion mechanisms of the vascular wall and consequently an important factor in the destabilization of coagulation-fibrinolysis processes, we cannot neglect the role of the anti-inflammatory pleiotropic effect of statins in preventing recurrent primary venous thrombosis and the development of the post-thrombotic syndrome. Statins reduce the level of inflammation markers: C-reactive protein (in the CARE, PRINCE, AFCAPS/TexCAPS studies), tumoral necrosis factor-α, -1β and -2 interleukin, fibrinogen, CD40L ligand. There exists an association between the high risk of VTE, the increase of plasmatic values of triglycerides (over 1.05 mmol/l) and the decrease of HDL cholesterol (under 1.79 mmol/1) (22). In this context, statins are benefic due to their well-known effect on the serum lipid spectrum.

CONCLUSIONS

VTE is associated with high morbidity and mortality. The optimal remedy for the prevention and treatment of VTE should combine the advantages of efficiency, minimal bleeding risk and ease of administration. Statins seem to meet the last two criteria, yet their efficiency has not yet been fully demonstrated. They cannot be suggested as alternative anti-thrombotic remedies instead of oral anti-coagulants in the treatment of acute of sub-acute venous thrombosis. Yet, clinical studies demonstrate that the use of statins is rational as far as VTE prophylaxis is concerned, long-term secondary prophylaxis included. Statin therapy is associated with a decrease of VTE incidence in the general population as well as with a decrease of the incidence of recurrences, when administered after the recommended 6-12 month anticoagulant treatment. Still, more studies are needed in order to prove the efficiency of this drug for such a condition and create the opportunity to extend the indications for this group of drugs for certain population categories.

THE DEGREE OF AGREEMENT BETWEEN HPV TESTING, PAP SMEAR AND COLPOSCOPY IN CERVICAL DYSPLASIA DIAGNOSIS (Abstract): **Material and methods:** The current study analyzed the degree of agreement between HPV testing, Pap smear, and colposcopic directed cervical biopsies. The study was performed on a group of 332 patients diagnosed and treated for cervical dysplasia at Cuza-Vodă Obstetrics-Gynecology Clinic Hospital and Suceava County Hospital between 2006 and 2011. **Results:** 190 patients (57.23%) were positive for HPV, 56 (35%) were positive for two HPV types and 42 (22.10%) for three or more HPV types. High grade cervical squamous intraepithelial lesion (HSIL) accounted for 88 (26.5%), low grade cervical squamous intraepithelial lesion (LSIL) for 92 (27.71%), atypical squamous cells of undetermined significance (ASC-US) for 69 (20.78%) and squamous cell carcinoma accounted for 5 (1.5%) of referral Pap smears. Colposcopic directed cervical biopsies reported no pathological abnormality (negative) in 64 (19.28%), HSIL in 105 (31.62%), LSIL in 83 (25%) and other lesions in 80 (24.1%) women. Exact degree of agreement between Pap smear and cervical biopsy was fair (k = 0.5) when analyzing for high grade cervical squamous intraepithelial lesion. The high-risk HPV types 16, 18, 66 and 68 and the low-risk HPV types 11, 54, 83, and 61 were the most frequently detected HPV types. **Conclusions:** The current study showed the fair agreement between Pap smear and colposcopic biopsy. Incorporation of HPV testing into the present Pap screening program has the potential to make screening for cervical cancer more effective, and a necessary prelude to assessing this is determining the prevalence of the high-risk types. **Key words:** CERVICAL CANCER, PAP SMEAR, COLPOSCOPY, CERVICAL BIOPSY, HPV TESTING

According to the American Congress of Obstetricians and Gynaecologist Practice Bulletin, it is estimated to be the second or third most common cause of cancer in women worldwide, despite the fact that a screening test, Pap smear, is available and has been demonstrated to reduce the incidence of the disease by at least seventy percent (1).

Several tests are required to screen and diagnose cervical dysplastic lesions: cervical cytology, colposcopy, colposcopic-guided cervical biopsy histopathology, HPV DNA.

Currently, there is great interest in the possible application of *Human Papilloma virus* (HPV) testing to supplement Pap screening for cervical cancer. Many epide-

miological studies provide evidence that persistent infection with specific types of HPV is a strong independent risk factor for the development of cervical intraepithelial neoplasia (CIN) and cervical cancer. Additionally, it appears that the predictive value of a negative HPV result together with a repeat Pap smear in women with an initial low grade Pap result is greater than 96 % (82.8-99.4%) (2).

Despite the improvement in detection, there is wide variation in clinician practice in relation to the types and sensitivity of tests used for the diagnosis of cervical dysplasia, and also in regards to the timing, schedule and duration of follow up for women after cervical dysplasia detection and treatment.

The current study analyzed the degree of agreement between HPV testing, Pap smear, and colposcopic directed cervical biopsies.

MATERIAL AND METHODS

The study was performed on a group of 332 patients diagnosed and treated for cervical dysplasia at Cuza-Vodă Obstetrics-Gynecology Clinic Hospital and Suceava County Hospital between 2006 and 2011.

The patient selection was done according to the following inclusion criteria: women 18 years or older who underwent Pap smear, HPV testing and colposcopic biopsy. The exclusion criteria included patients that underwent total hysterectomy or followed previous treatment for CIN.

RESULTS

The cohort for this study consisted of 332 women who underwent HPV testing, Pap smear and final colposcopic directed cervical biopsy procedure for cervical dysplasia during the study period (tab. I).

The mean age for all participants was 36.9 years of age. The respondents ranged in age from 21 to 68 years old. In this study, the largest group of women were within ages 31-40 (fig. 1).

TABLE I
Characteristics of studied patients

Age (mean, SD)	36.9±10.5years
Nulligravida	134 (40.36%)
Nulliparous	149 (44.87%)
Non-smoker	194 (58.43%)
Smoker	123 (37.05%)
No smoker information	15 (4.52%)
No contraception	105 (31.62%)
Oral contraception	123 (37.04%)
Other contraceptive methods	104 (31.32%)
Hormonal replacement therapy	4 (1.2%)

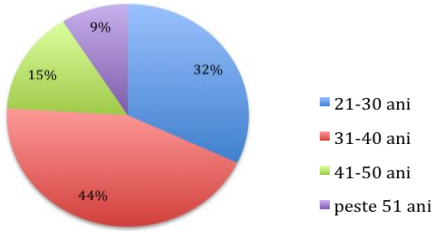

Fig. 1. Distribution of studied patients according to age group

HSIL accounted for 88 (26.5%), LSIL for 92 (27.71%), atypical squamous cells of undetermined significance (ASC-US) for 69 (20.78%) and squamous cell carcinoma (SCC) accounted for 5 (1.5%) of referral Pap smears in those women with cervical dysplasia (table II). Pap smear was negative in 78 cases (23.49%).

Colposcopic reported no pathological abnormality (negative) in 64 (19.28%), HSIL in 105 (31.62%), LSIL in 83 (25%) and other lesions in 80 (24.1%) women.

The degree of agreement between Pap smear and cervical biopsy histopathology

was examined. The overall kappa value was 0.3 and it represented poor agreement. When the degree of agreement was compared for HSIL only, the kappa value was 0.5, which represented fair agreement. The sensitivity and specificity was not calculated, because these parameters were beyond the objectives of the current study.

From the total of 332 patients, 190 (57.23%) were positive for HPV. The high-risk HPV types 16, 18, 66 and 68 and the low-risk HPV types 11, 54, 83, and 61 were the most frequently detected HPV types (fig. 2). 56 patients (35%) were positive for two HPV types and 42 (22.10%) for three or more HPV types (fig. 3).

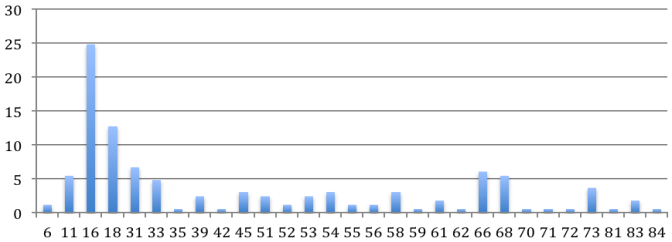

Fig. 3. Frequencies of HPV types in the study group

Table II shows the OR's and 95% CI for the selected variables and cervical dysplasia adjusted first for age and then for all the other variables.

TABLE II

Odds ratios (OR) and 95% confidence intervals (95% CI) for cervical dysplasia and age, adjusting for the other variables and then additionally adjusting for HPV

Age group	Basal OR	Basal 95% CI	Fully adjusted OR	Fully adjusted 95% CI	HPV adjusted OR	HPV adjusted 95% CI
21-30	1.0	Referent	1.0	Referent	1.0	Referent
31-40	1.02	0.6-1.7	1.03	0.6-1.7	1.5	0.8-2.7
41-50	0.45	0.2-0.9	0.43	0.2-0.9	1.3	0.6-2.8
>51	0.33	0.1-0.7	0.32	0.1-0.8	0.66	0.3-2.2

Women aged 30 and younger had the highest OR for cervical dysplasia and it was less than half for the women over 30. This OR according the age became insignificant in the fully adjusted model and in fact it was HPV that most influenced this change The age-adjusted odds of having cervical dysplasia increased significantly and dramatically with the increasing viral load. The p-value for this trend is <0.0001.

DISCUSSION

Using histopathology, the sensitivity of colposcopy for cervical abnormalities is high at 96.0 to 97.0%, but specificity is lower, at about 48 to 54.8% (12). Gage et al. (2006) reported that the combined sensitivity of colposcopy for diagnosing HSIL increased to 83.3% from 68.3% when more than one cervical biopsy was taken (7).

This study found a strong association (OR: 28) between high-risk HPV types and cervical dysplasia. Comparison with other studies has been difficult because of the different techniques used for detection and the different combinations of strains being tested for, nonetheless, OR's of over 15 have been reported in a review of case-control studies that used reliable methods for HPV DNA

A series of studies have revealed that a

unique feature of HPV testing is the ability to predict the subsequent development of cervical cancer precursors among cytological negative women (9).

The most important determinant of HPV infection is age, with the highest prevalence (60-80%) between the ages 21 and 40. Infection in these individuals, however, appears to be transient and prevalence decreases to about 10% by age 30 and 3% by age 50 (10).

CONCLUSIONS

Cancer of the cervix is a preventable disease and, theoretically, with regular screening dysplasia can be detected early and invasive disease can be prevented. . The protective effect of cervical cytological screening (relative risks of 0.25-0.37) among women who have been screened cytologically compared to those who have never been screened increases with an increased number of screening smears and decreases with the increased length of interval since the last smear. Although these results establish that the cytological screening program is successful, an unacceptable number of women who have been cytologically screened develop invasive cervical cancer because of too many false negatives. The current study showed the fair agreement between Pap smear and colposcopic biopsy. Incorporation of HPV testing into the present Pap screening program has the potential to make screening for cervical cancer more effective, and a necessary prelude to assessing this is determining the prevalence of the high-risk types. To summarize, in our opinion, the approach of investigation and management of women with cervical dysplasia is a stepped process. Initially Pap smear is used to screen women followed by colposcopic examination and colposcopic biopsy of those women whose Pap smear is reported as abnormal. Based on histopathology of colposcopic guided cervical punch biopsy women will be advised to undergo final cervical excision procedure.

PARTICULARITIES OF ORAL HEALTH PROBLEMS IN PATIENTS WITH ALZHEIMER`S DEMENTIA (Abstract) **Aim:** Dementia and especially Alzheimer`s dementia represent one of the most important disorder of this century with a lot of negative consequences for the patient himself, but also for family and community. The essential features of dementia are represented by multiple cognitive deficits, at least one of the following: aphasia, apraxia, agnosia, or a disturbance in executive, which diminished the quality of life of these patients. Unfortunately, in majority of the cases, the oral health care of these patients does not represent a priority. The aim of our study is to establish a series of general coordinates on the pattern of development of oral diseases in patients with dementia. **Material and methods:** We focused on the clinical evolution of 50 patients from "Socola" Institute of Psychiatry Iasi, with the diagnosis of Alzheimer`s dementia, according to ICD 10 criteria, from the point of view of the general and dental status, the prognosis and the therapeutic possibilities. **Results:** Our results reveal that 78% of patients with moderate dementia had partial and total edentation and 56% of patients with severe dementia had partial edentation, while 21% total edentation. **Conclusions:** Thus, in this context, increasing the quality of life of these patients means to improve the general condition of the elderly, which is closely related to the maintenance of natural teeth and the development of well-adapted prostheses.
Keywords: ORAL HEALTH, DEMENTIA, QUALITY OF LIFE.

Dementia is a progressive and irreversible neurodegenerative disorder characterized by a variety of symptoms: cognitive impairment, memory disorders, progressive deterioration of daily exercise capacity, and a range of neuropsychiatric symptoms. According to the World Alzheimer Report from 2015, regarding "The Global Impact of Dementia", the number of people diagnosed with dementia will increase from 46 million, in the present, to 131,500,000 by 2050 (1). Statistical data show that about 9.9 million new cases of dementia will be diagnosed this year around the world. Thus, a new case is diagnosed every three seconds. According to the report, about 94% of people living with dementia in low-income and middle-income countries are

home-grown. In many of these countries there is no developed nursing and specialized care network for people with dementia (1, 2).

The world population is experiencing an aging process, the number of people over 60`s years old suffered an increase of 450 million in only 40 years. The structure of the elderly population has changed to more than 50% in developed countries, the most aging being from the European area. Dementia caused by Alzheimer's disease is the most common type, representing approximately 60% of all dementia patients. As for the link between age and illness, it is estimated that 5% of persons of 65 years old have dementia in Alzheimer's disease, and at the age of 85, the rate goes up to 25%(1, 3, 4, 5).

Oral health problems may adversely affect the quality of life of patients with Alzheimer's dementia. However, as the patient suffering from Alzheimer's dementia requires a wide range of care, often oral health care is not a priority. Increasing the quality of life and improving the general condition of the elderly is closely related to the maintenance of natural teeth and the development of well-adapted prostheses (6, 7, 8). Given that cognitive functions and motor skills are progressively altered in patients with Alzheimer's dementia, this circumstance can lead to a level inadequate control of biofilm and oral hygiene. Alzheimer's dementia is a complex pathology that, beyond the loss of cognitive function, leads to alteration of the ability to perform common daily activities (7, 9, 10).

The spectrum of adverse effects attributed to the medication used to control the symptomatology specific to dementia also reaches the oral sphere, emphasizing the issues already exposed. On the one hand, anti-dementia medication (anti-acetylcholinesterase) causes hypersalivation, which makes it more difficult to maintain a dry field during dental treatment and causes difficulties in maintaining a mobilizable prosthesis (10, 11, 12, 13). On the other hand, xerostomia is a common side effect associated with adjuvant medication used in dementia, such as antidepressants and benzodiazepines. Insufficient salivation reduces the lubrication of mucosal tissues, increasing the potential for mucosal ulceration, and increasing the difficulty of maintaining a mobilizable prosthesis. At the same time, xerostomia leads to alteration of normal oral flora, causing gingival plaque formation, predisposing to periodontal disease, dental caries and increased risk of infection (14, 15, 16).

MATERIAL AND METHODS

The study included 50 patients admitted to acute department III, V and VII in “Socola” Psychiatry Institute Iasi, during the year 2017. The study group consists of roughly equal numbers of males and females with a slight superiority of female gender (56% female and 44% male). Clinical and anamnestic data were extracted from the observation sheets of these patients. The dental evaluation was conducted within the dental office of the Institute. The criteria for inclusion in the study were: confirmed diagnosis of Alzheimer's dementia, both with early onset and with late onset and edentation.

Alzheimer's dementia diagnosis is established according to ICD 10 criteria (17). Dementia in Alzheimer's disease with early onset: The criteria for dementia in Alzheimer's disease must be met, and the age at onset being under 65 years; In addition, at least one of the following requirements

must be met:(a) evidence of a relatively rapid onset and progression; (b) in addition to memory impairment, there is aphasia (amnesic or sensory), agraphia, alexia, acalculia, or apraxia (indicating the presence of temporal, parietal and/or frontal lobe involvement).

Dementia in Alzheimer's disease with late onset: The criteria for dementia in Alzheimer's disease must be met and the age at onset must be 65 or more. In addition, at least one of the following requirements must be met:(a) evidence of a very slow, gradual onset and progression (the rate of the latter may be known only retrospectively after a course of three years or more); (b) predominance of memory impairment over intellectual impairment (see general criteria for dementia).

Once the patient is diagnosed, the progression of the disease is clinically and anamnestically assessed, also with the help of the Mini Mental State Examination, a nonspecific instrument that has no diagnostic but merely indicative role. At the same time, scores on the Hamilton Depression Rating Scale of patients with Alzheimer's dementia showing negative hypertimic symptoms are also recorded.

In terms of edentation, patients were in one of the following classes: partial edentation, when at least three consecutive teeth in the lateral area or four front teeth are missing; subtotal edentation, when the arcade remains at most three teeth; total edentation, lack of all teeth.

Oral Health Indicators used in this study are the OHI index and the CAO-D index, both of which are internationally recognized by dental scientific organizations. The OHI is the sum of the soft deposit index and the tartar index.

The soft deposit index: 0-absence of soft deposits; 1-soft deposits covering up to 1/3 of the surface of the teeth; 2-soft deposits covering 1/3-2/3 of the surface of the teeth; 3-soft deposits covering more than 2/3 of the surface of the teeth.

*Tartar index:*0-the absence of tartar; 1-supragingival tartar covering not more than one-third of the surface of the tooth; 2-supragingival tartar that covers between 1/3 and 2/3 of the exposed tooth surface; 3-surgingival tartar covering more than 2/3 of the tooth surface.

RESULTS

The results obtained by correlating the degree of dental affection with the degree of psycho-cognitive impairment and the presence of depression symptoms, apathy and serious difficulty in targeting, indicate the existence of a direct relationship between these variables. Thus, most patients with dementia have associated oral pathology, the most significant, with an increased impact on the patient's outstanding function being the edentation of different degrees. It is noticeable that in most cases we face subtotal edentation, followed by the total edentation, present in a significant percentage.

Distribution of cases by age reveals a predisposition for the eighth decade. It should be noted that patients are not newly diagnosed cases and clinical and anamnestic information in the observation sheets reveals that most of them were originally dementia Alzheimer type, with early onset (tab. I, fig. 1).

Patients with dementia develop depressive symptoms of varying degrees of intensity, the group of those with overweight depressed mood associated with 92% of total and subtotal edentation (fig. 2).

The distribution of the CAO-D index in patients in the study group is the following:

number of caries-1,12 teeth; number of absent teeth - 4.48; number of teeth closed - 0.32. Regarding the oral hygiene index, 84% of the patients obtained a weak index, 14% moderate and only 2% of the patients a good hygiene index.

TABLE I

The distribution of cases by age and sex

Age	Male		Female		Total	
	Number of patients	%	Number of patients	%	Number of patients	%
50-59	1	2	2	4	3	6
60-69	4	8	6	12	10	20
70-79	11	22	15	30	26	52
80-89	6	12	5	10	11	22
Total	22	44	28	56	50	100

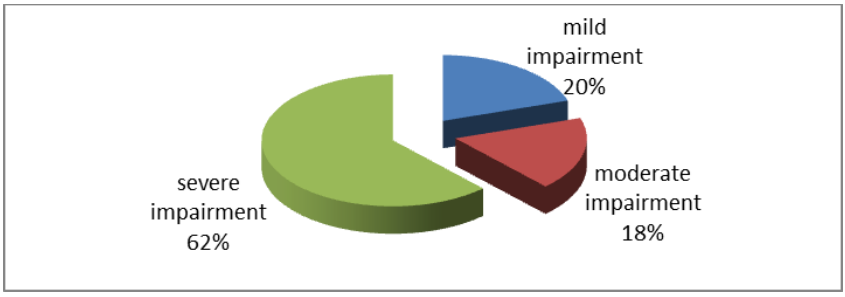

Fig. 1. Degree of cognitive impairment

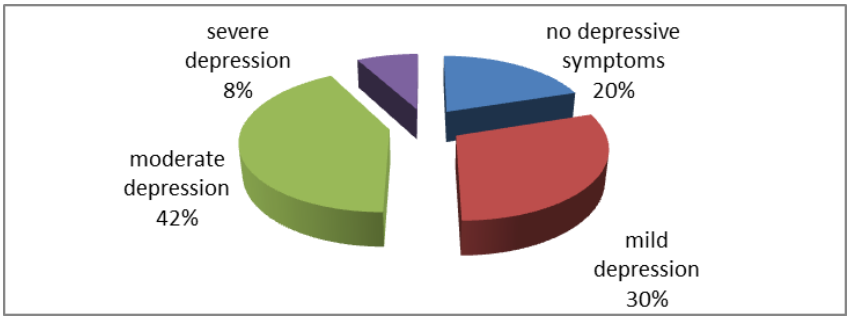

Fig. 2. Depressive symptoms in patients with Alzheimer`s disease

Of all patients included in the present research, it is noted that there are none that do not show a degree of edentation (fig. 3).

In addition, 78% of patients with moderate dementia had partial and total edentation and 56% of patients with severe dementia had partial edentation and 21% had total edentation.

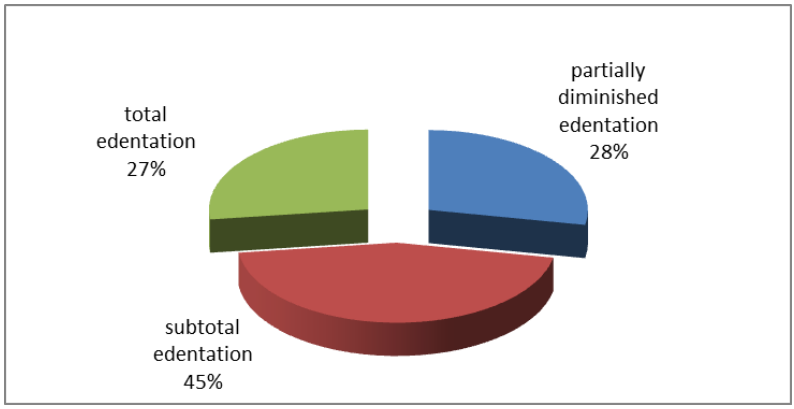

Fig. 3. Edentation in patients with Alzheimer`s disease

DISCUSSION

In 2014, the General Assembly of the World Federation of Public Health Associations issued a resolution on the importance of oral health of patients with dementia (18, 19). The prevalence of dementia is growing globally. Patients with dementia gradually install serious communication difficulties with those responsible for their care. Recent studies show that the precarious oral condition of people with dementia is directly correlated with socio-economic status, but also with demographic variables (20). Thus, the results of this research are linked to the results obtained in the literature, emphasizing the direct relationship of a precarious socio-economic status and a greater severity of the pathology in the oral sphere in the patients diagnosed with dementia (21).

In addition, as the present research shows, patients with dementia receive psychotropic treatment, especially for controlling behavioral and psychotic symptoms, but also for controlling depressive symptoms that can cause xerostomia and dry mouth syndrome, favoring candida infections, but also the appearance of dental caries and, on the other hand, sialorrhea. In addition to this, patients with dementia either forget or lose their ability to ensure daily oral hygiene. Thus, the persons responsible for these patients (family members or medical staff) must ensure this process (22).

Depending on the evolutionary state of dementia, oral health becomes a growing problem, being totally dependent on the care of others. Multiple studies have directly correlated the degree of cognitive impairment with the precariousness of oral health (23). In the same vein, the present research shows that most cases of severe edentation (subtotal and even total) occur in patients with moderate to severe dementia, who are, moreover, frequently hospitalized in psychiatric or institutionalized services.

A study conducted in Sweden between the years 2007 and 2015 (24) shows that as dementia progresses, addressability for dental services decreases significantly. At the same time, the MMSE score has been shown to be a remarkable predictor of edentation, in the context of increasingly poor dental hygiene and the appearance and evolution of dental caries. These elements are also found in the results of this research. In addition,

the same study is the first longitudinal research that examines oral health in premorbid stages and after diagnosis of dementia. Unlike our study, it reports the results to the population with cognitive impairment before dementia. This study only indicates the prevalence of oral pathology among patients with already diagnosed dementia and especially among those with moderate-severe dementia (24, 25).

In 2017, a study realized by Campos et al. (26) shows that the masticatory efficacy in Alzheimer's dementia remains below the control level, as indicated by our study, which highlights the severity of the masticatory and swallowing disorders in direct proportion to the evolutionary stage of dementia.

Cognitive decline, apathy and apraxia, symptoms that characterize the average progression of dementia are responsible for the lack of interest and inability to perform oral hygiene techniques (24). In advanced stages, Alzheimer's disease leads to total disability, augmented by the associated general health problems and by the diverse oral pathology resulting in even greater dysfunctionality. Loss of teeth reduces masticatory capacity, increasing the risk for serious swallowing and denaturing disorders (25).

The results of this research relate to the results of international general statistics, revealing a remarkable share of depressive symptoms in dementia, which correlates with specific progressive deterioration, aggravates apato-abulic phenomena, as well as apraxia itself, that correlates directly with the appearance and evolution of oral pathology, reaching to the edentation.

CONCLUSIONS

This study could be the premise of a program designed to increase the quality of life of patients with dementia, including oral health care among all the other fundamental problem of these patients. The results of our study show once more that beyond the psychiatric symptomatology, the patient with dementia associates a series of general health problems that hinder the evolution of the underlying disease. Through the correct, multidimensional approach of the patient with dementia, by managing all psychiatric symptoms such as depression, general health problems, including oral pathology and the risk of edentation, can be avoided or alleviated.

EXPRESSION OF EXTRACELLULAR MARKERS AS CRITERIA FOR TREATMENT OF PERIPHERAL ARTERIAL OCCLUSIVE DISEASE (Abstract): During the last decade, mesenchymal stromal cells (MSC) have been used in medical therapeutics, especially for reperfusion in peripheral arterial disease, ischemic cardiomiopathy and myocardial infarction. Studies demonstrated that membrane proteins are important in MSC endothelial differentiation. **Aim:** To determine the expression of extracellular markers of MSC, in order to ascertain if some expressed proteins (MSC specific cluster of differentiation proteins, essential for MSC characterization and proteins which have a role in adhesion and migration) have capability to induce angiogenesis **Material and methods**: To detect the expression of these proteins and confirm the presence of MSC and other essential proteins with important role in adhesion and migration, cells from five donors were fully assessed by flow cytometry (surface expression), differentiation assays (MSC differentiation into osteocytes, adipocytes, and chondrocytes), and qRT-PCR (gene relative expression). **Results**: Our results were in agreement with other reports, with small exceptions, related especially to donor dependent conditions. The surface expression of beta 1 subunits correlated with a high gene expression on RNA level. **Conclusions**: MSC had all specific characteristics. Surface marker expression was in agreement with pervious findings. These cells can be used for endothelial progenitor cells further differentiation. Beta 1 expression suggests a high potential of the MSC to form capillary lumen, thus for further artery formation and efficient angiogenesis. **Key words**: PERIPHERAL ARTERIAL DISEASE, ADULT STEM CELL, MEMBRANE PROTEINS.

In the last decade mesenchymal stromal cells (MSC) were used as medical therapeutics. MSC can be isolated from bone marrow, peripheral blood, fat, skin, vasculature, and muscle, where they most likely are responsible for normal tissue regeneration, as well as for a response to injury (1). MSC are negative for primitive hematopoietic cell markers. Individual clones of cell lines derived from MSC have different potentials for differentiation, indicating different stages of determination and levels of plasticity. MSCs are a varied population of plastic-adherent cells that show a fibroblast-like morphology, they are forming colonies when grown at clonal densities (referred to as colony forming units fibroblast or CFU-F) (2), and can differentiate into bone, cartilage, and fat cells (3). Human MSCs have been defined by the positive expression of the cell surface antigens CD73, CD90, CD105 and a lack of expression of hemato-

poietic antigens including CD11b or CD14, CD34, CD45, CD79 or CD19, and HLA-DR (4). A comprehensive list of surface antigen expression on MSC was recently published, but variability still exists within MSC populations due to differences in the species, tissue source, and the *in vitro* culture conditions used. To deal with this problem it was released an accord position paper stating the nominal criteria required for essential MSC characterization (4).

Molecular cardiology is a new direction of modern research world with promising results in the field of angiogenesis, not only in the periphery but also heart. In this disease the opening of new horizons for cell therapy, especially therapy with adult stem cells and vascular growth factors that have direct action on progenitor cells to endothelium, which is supposed to circulate freely within the bloodstream and have the ability to become endothelial cells to form capillaries, arterioles and finally arteries, or by autollogus MSC transplantation, to improve angiogenesis, by rising the number of endothelial progenitor cells at the lesion site.

Integrins are receptors that mediate intercellular and intracellular contacts as well as the extracellular matrix (ECM). They also play a role in cell signaling and regulate cellular shape, motility, and the cell cycle. The receptors inform a cell about the environment and the cell responds in consequences. These molecules have an inside-outside signaling possibility. They transduce information from the ECM to the cell as well as revealing the status of the cell outside, allowing rapid and flexible responses to changes in the environment (5). There are many types of integrin, hosted on cells surface. Integrins are of vital importance to all animals and have been found in all animals investigated, from sponges to mammals, being extensively studied in humans. Integrins are working with other proteins such as cadherins (transmembranare molecules which mediate cellular adhesion by calcium dependent mechanism), immunoglobulin superfamily cell adhesion molecules, selectins and syndecans, have the role to mediate cell-cell and cell-matrix interaction and communication. The integrin role is not fully known, a recent study showed that beta 1 integrin have an important role in establishing the endothelial cell polarity and arteriolar lumen formation (6). A final aspect of the vascular occlusion phenotype is that the ECs occluding the lumen exhibited an over accumulation of vacuoles within their cytoplasm. This accumulation will merge and in the end will form endothelial lumen. MSC can home to damaged tissue, process regulated in part by integrins.

MATERIAL AND METHODS

Human MSC were obtained from BM, from five donors, it was harvested from the iliac crest and collected. The obtained sample is further used to isolate MSC, using their property of adherence to culture plastic flask under standard culture condition. Mesodermal differentiation assays were performed using standardized differentiation media, and the proposed protocol was respected. The staining was performed with: Oil-red-O4 for adipocytes, alkaline phosphatase for osteocytes, and with Toluidin Blue for chondrocytes. Differentiation was visualized using light microscopy.

Surface expression was detected by flow cytometry. The cells were labeled to identify the specific markers (4). MSC were phenotyped to ensure the absence of the leukocyte markers CD45, endothelial marker CD34, and the presence of CD105

and CD73. IgG2a and IgG2b isotype control antibodies were used. To identify specific integrins fluorescently labeled conjugated or unconjugated rat anti-mouse antibodies were used: CD11a, CD11b, CD29, ITGAL, ITGAM, ITGAX, ITGAD, ITGB2, ITGB3, ITGB1, ITGA4, and ITGA5.

Quantitative Real-Time Polimerase Chain Reaction (qRT-PCR) was performed on Applied Biosystem StepOne. Real Time PCR System, with TaqMan primers, using the same estimated amount of DNA for each experiment, it was obtained from 1 μg RNA transcription. Glyceraldehyde 3 phosphate dehydrogenase (GAPDH) was used as a positive control, being one of the most commonly housekeeping genes used for gene expression. It serves as a positive control for northern and other expression studies. StepOne® program was used and after assigning target samples on plate setup, the method was set to run. The amplification plot (target amplification generates fluorescent signals which are collected by the instrument) and the data analyze is done via StepOne® software and results were export to Graph Prism for analysis.

RESULTS

We identified the differentiation potential of MSC into osteocytes, adipocytes, and chondrocytes (fig. 1). Oil Red-O stain was used to identify neutral triglycerides. The microscope analysis reveals the red fat vesicles in adipocytes differentiated cells (fig. 1 B). Kossa Stain was used to identify the presence of calcium deposits (fig. 1 C). Chondrocytes differentiation can be assessed after Toluidin Blue staining, (stains in lila colour) (fig. 1 D).

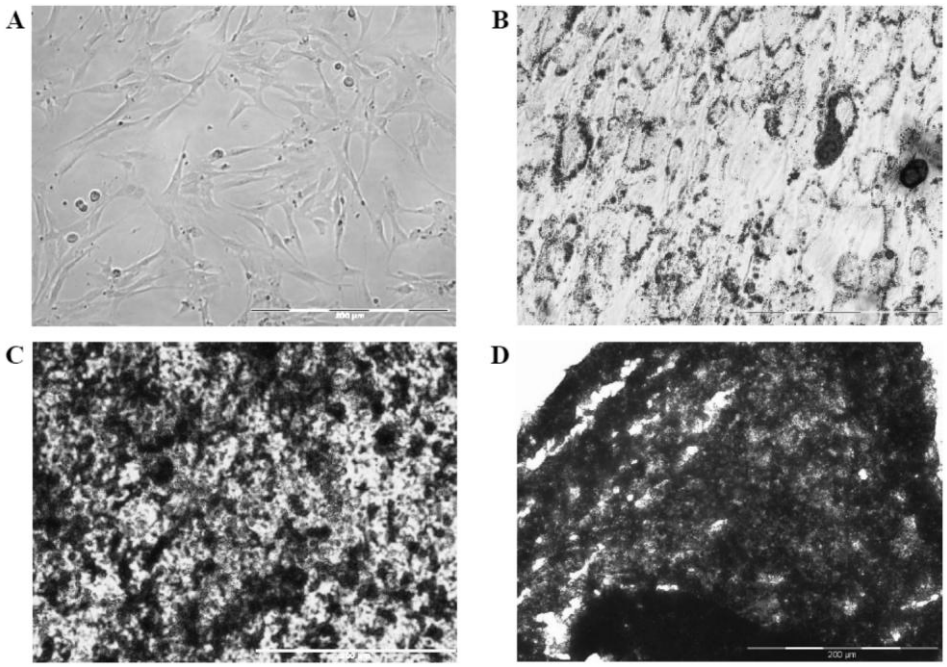

Fig. 1. Differentiation of MSC (n=5). A. MSC culture before differentiation, B. Adipocyte differentiation - Oil Red O staining, C. Osteocyte differentiation - von Kossa staining. D. Chondrocyte differentiation - Toluidin Blue staining (100 x magnification).

To complete the MSC characterization specific markers had to be identified on their surface. The isolated MSC respected the minimal characteristics of surface markers. They were positive for: CD105, CD90, CD73, and negative for: CD45, CD34, CD11b (as it is seen in fig. 2). The right shift at CD105, Cd73 and CD90, is representative for positive cells. The overlapping of CD11b, CD45, CD34, represents their absence in comparison with IgG isotype control, which as usual is considered negative. As a result we know that the isolated cells were MSC. They respect all tree conditions of tissue growth for MSC (adherence to plastic, tri-lineage differentiation and specific surface markers).

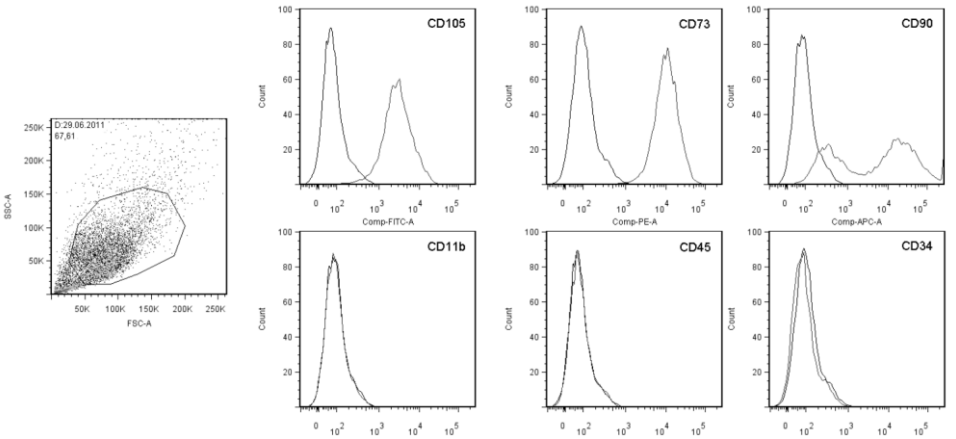

Fig. 2. MSC characteristic markers expression (n=5)

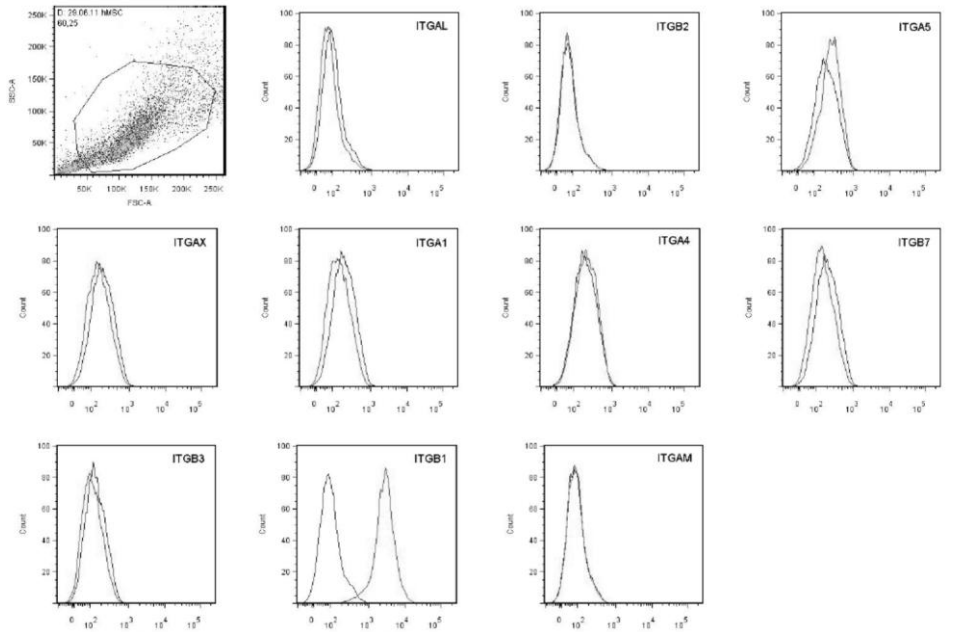

Fig. 3. Integrin expression on MSC surface (n=5)

The flow cytometric analysis was performed to identify integrin subunits expression on isolated cells. The results show that **l**ymphocyte function-associated antigen 1 (LFA-1, also known as alpha L/beta 2 integrin) is not expressed, compared with IgG isotype control (fig. 3). All tested alpha subunits (alpha 5, alpha X, alpha 1, alpha 4, alpha M, alpha L) are absent, some beta tested subunits (beta 2, beta 3 and beta 7) are negative, in contrast with beta 1 subunit.

To confirm the results from pervious experiment we decided to evaluate integrin expression at RNA level. For this purpose we performed qRT-PCR analysis, in order to assess gene expression Using GAPDH as the housekeeping gene. The analysis confirmed the flow cytometry for absence of all alpha integrin subunits, exception alpha X, discreet expression in two donors. Beta subunits have a relative good expression in beta 3, beta 5 integrins, with a small donor dependent variation. In contrast beta 1 integrin subunit has a high donor dependent variation, seen in a high standard deviation (fig. 4).

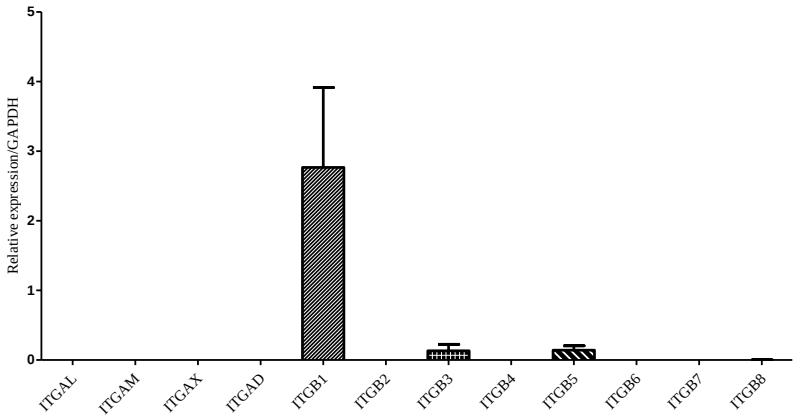

Fig. 4. Relative expression of integrins in five different donors (We can see donor dependent expression clearly in beta 1 integrin subunit and in consequence a high standard deviation) (n=5).

DISCUSSION

Stem cell therapy is a type of interventional medicine, which has the aim to introduce new cells into damaged tissue in order to treat a disease or injury (7). The ability of stem cells to give rise to subsequent generations, with variable degrees of differentiation capacities, offers significant potential for generation of tissues that can potentially replace damaged areas in the body, with minimal risk of rejection and side effects (8).

A number of stem cell therapies exist, but most are either at experimental stages or costly, with the notable exception of bone marrow transplantation for leukemia treatment. Medical researchers anticipate that adult and embryonic stem cells will soon be able to treat many types of disorders using stem cells. Nevertheless, before stem cell therapeutics can be applied in the clinical setting, more research is necessary to understand their behavior upon transplantation, as well as the mechanisms of interaction with the microenvironment (9). As described in literature over the last years, the MSC have a significant therapeutically effect over the other medicine cell types. One of the most

important advantages of MSC is their relevant immune modulatory effect post intravenous administration (10). It has been shown that these cells have the possibility to be transplanted without causing immune rejection. Their potential has been proposed to confer main functions in securing the support of hematopoiesis, and has been involved in functions in tissue repair such as osteogenic remodeling or cartilage generation (11). It is known that after donor isolation, the MSC can be expanded in culture, cryopreserved, and then used for different acute phases and chronic clinical conditions in various patients (12). Currently, it is known that MSC follow a cascade of signaling molecules, due to their mobilization into bloodstream, but there are several other factors involved in, which are still unknown (13).

The current work aimed to analyze five MSC donors. The isolated MSC were differentiated into three specific lineages as it was described before. These findings were according to other researches findings, where MSC were able to differentiate into three mesodermal layers: adipocytes, osteocytes, and chondrocytes (3), (14). MSC were able to differentiate in our case into tree mesodermal layers: adipocytes, osteocytes and chondrocytes. The results from flow cytometry confirm the expression of MSC markers like: CD105, CD90, CD73 as well as the absence of Cd11b, CD34 and CD45 markers (4). Integrin expression was assessed using flow cytometry and gene expression quantification. All analyzed alpha integrin subunits were absent (alpha 1, alpha 4, alpha 5, alpha X, alpha M, alpha D, alpha L) as well as some beta subunits (beta 2, beta 7, beta 4, beta 6). A relative high expression for beta 3 and beta 5 integrin subunits was observed. Only beta 3 was analyzed flow cytometry and qPCR, and is negative in flow cytometry test, while gene expression is low. This can be explained by a possible cellular modification at integrin level when we prepared cells for flow cytometry (the surface molecules are cut off in the time of trypsinisation), or the protein is not expressed on surface. Beta 5 integrin subunit has a relative gene expression, but the surface expression couldn't be detected in flow cytometry. Beta 5 integrin subunit has a relative gene expression, but the surface expression couldn't be analyzed by flow cytometry, because we didn't had the specific surface antigens.

Our results are in agreement with Semon (15), that observed that over 80% of MSC express beta 1 integrin subunits. In contrast we did not find any expression of beta 2 and other alpha subunits. Furthermore, beta 1 is the integrin which has variation among different MSC donors.

CONCLUSIONS

The experiment performed isolated MSC that have all three specific characteristics: adherence to plastic flasks, trilineage differentiation, and surface marker characterization. The integrin expressions on MSC are donor dependent, more pronounced in the case of beta 1 integrin subunit, in this case we had high donor variability. The surface marker expression was in agreement with pervious findings, and this want to demonstrate that we will work with MSC, for EPC further differentiation. The high beta 1 integrin expression suggests a high potential of the MSC to form capillary lumen, for further artery formation and an efficient angiogenesis. The results weren't fully in agreement with previous findings and the literature discrepancies were not totally understood.

3. Disciplina Medicină de Urgenţe

PHARMACOEPIDEMIOLOGIC INVESTIGATIONS REGARDING THE INTERACTIONS BETWEEN ORAL ANTICOAGULANTS AND OTHER DRUGS IN PATIENTS WITH HAEMOSTATIC DISTURBANCES (Abstract): A**im:** To evaluate drugs interactions with oral anticoagulants and their clinical relevance, in patients from two emergency departments in hospital. **Material and methods:** Retrospective study, during one year, on patients (between 18 and 85 year old) with haemostatic disturbances admitted at two emergency departments in „Sf. Spiridon" Hospital, Iaşi and in Piatra Neamţ Public Hospital, consisted in medical records analysis**:** the diagnostic, therapy recommended. Data were scored and statistically analyzed by t test (Windows Excel). The experimental protocol was in agreement with recommendations of the "Gr. T. Popa" University Committee for Research and Ethical Issues. **Results and conclusions:** Analysis and statistical processing of data shows that during the period of the study, 69 patients, which received oral anticoagulant therapy associated with different other medication belonged to the 60 and 80 years age group. The findings suggests the pathology is represented especially by atrial fibrillation and cerebral ischemic diseases. The correlation between the therapy consisting in OAC and amiodaronum or statines drugs association and International Normalized Ratio (INR), revealed a high level of anticoagulation and an increase of hemorragic complications. **Key words:** ORAL ANTICOAGULANTS, DRUG INTERACTIONS, PHARMACOEPIDEMIOLOGY, HAEMOSTATIC.

Medicaţia anticoagulantă este folosită pentru prevenirea trombemboliilor sistemice la pacienţii cu fibrilaţie atrială cronică, cu afecţiuni cardiace valvulare sau cu proteze valvulare, în tromembolismul pulmonar primar sau secundar. Sunt, de asemenea, utilizate în prevenţia trombemboliilor la pacienţii cu infarct miocardic acut şi angină pectorală, la cei cu valve biologice sau după intervenţii chirurgicale sau ortopedice (1,2,3).

International Normalized Ratio (INR) este indicatorul cel mai utilizat în evaluarea eficacităţii terapiei anticoagulente orale. Riscul complicaţiilor hemoragice sau tromboembolice creşte dacă INR este în afara intervalului terapeutic recomandat. Efectul ACO este influenţat de diverşi factori genetici, medicali, alimentari, comorbiditate, etc (4,5).

Studiul urmăreşte realizarea unei analize retrospective privind interacţiunile medicamentoase ale terapiei cu anticoagulante orale, la pacienţii cu tulburări ale hemostazei la Unitatea de Primire Urgenţe (UPU) din Iaşi şi Piatra-Neamţ.

MATERIAL ŞI METODE

S-a realizat un studiu descriptiv transversal, pe un lot de 368 de pacienţi desfăşurat în cursul anului 2009 constând în culegerea datelor specifice privind interacţiunile medicamentelor la pacienţii trataţi cu anticoagulante orale şi nivelul acestora anticoagulare la cei asistaţi în UPU de nivel judeţean, pentru diverse afecţiuni care necesită administrarea de anticoagulante orale pe termen lung; evaluarea nivelului anticoagulării la pacienţi care au primit alte tratamente, cu referire directă la amiodaronă şi la statine; standardizarea şi predictibilitatea aplicării terapiei anticoagulante concomitent cu alte terapii în practica medicală umană; stabilirea unor corelaţii între nivelul terapeutic al anticoagulantelor orale şi diverse medicamente utilizate simultan.

Criteriile de includere lotul de studiu au fost reprezentate de: persoane cu domiciliu stabil în localitate; vârsta între 18-85 ani; prezentarea la UPU pentru efectuarea analizelor lunare sau de urgenţă. Criteriile de excludere au fost vârsta sub 18 sau peste 85 ani; date incomplete; persoane necooperante sau cu domiciliu stabil în alte localităţi. Studiul s-a efectuat cu acordul Comisiei de Etică a UMF ''Gr.T. Popa'', Iaşi.

Informaţiile preliminare s-au obţinut analizând datele din registrele de consultaţii şi fişa de evaluare a stării de sănătate a pacientului elaborată in cadrul UPU, reţinând vârsta, statusul marital, nivelul educaţional laborator şi rezultatele de laborator Timpul Quick, INR, aPTT şi cele clinice: TA, parametrii antropometrici, tratamentul.

Pentru prelucrarea şi evaluarea informaţiilor acumulate s-a stabilit un mod de codare şi înregistrare a datelor; stocarea acestora în calculator cu sistem de operare Windows 7; interpretarea statistică cu ajutorul programului SPSS 17.0(8).

REZULTATE ŞI DISCUŢII

1.Unele caracteristici demografice ale loturilor incluse în studiu. În anul 2009 la UP„Sf. Spiridon" Iaşi au fost asistaţi 237 pacienţi cu tulburări ale hemostazei, iar la UPU a Spitalului Judeţean de Urgenţe Piatra Neamţ, 131, la ambele unităţi predominând grupurile de vârstă 61 – 80 de ani, urmate de 51 – 60, şi peste 81 ani (Tab. I).

Analiza repartiţiei pe sex a evidenţiat că la UPU „Sf. Spiridon" Iaşi, 128 (53,8%) au fost pacienţi de sex feminin, iar la Piatra Neamţ 80 (61,1%) de sex masculin.

TABELUL I

Structura pe grupuri de vârstă a pacienţilor asistaţi la UPU Iaşi şi Piatra Neamţ, în anul 2009

Grupul de vârstă (ani)	Unitatea Primire Urgenţe			
	Spitalul „Sf. Spiridon" Iaşi		Spitalul Judeţean Piatra Neamţ	
	Nr.	%	Nr.	%

61 - 70	45	18,9	31	23,7
71 - 80	91	38,2	56	42,7
peste 81	61	25,6	16	12,2
TOTAL	238	100	131	100

2. Distribuţia pacienţilor incluşi în studiu, la cele două UPU, în relaţie cu diagnosticul principal şi cel secundar.

La UPU „ Sf. Spiridon ” Iaşi, diagnosticul principal a inclus 7 afecţiuni din care pe primul loc s-a situat Fibrilaţia atrială (FA – 57,1%), urmat de Sindromul coronarian acut (SCA – 15%) şi de Accident la ACO (14,3%).

Rezultatele determinărilor TQ, INR şi aPTT diferenţiat pentru fiecare din cele două UPU (tab. II, III, IV).

Rezultatele determinărilor TQ, INR şi aPTT ale pacienţilor admişi în studiu în Spitalul Judeţean de Urgenţe din Piatra Neamţ sunt sistematizate în tabelele V, VI, VII.

Total	131	100,0	100,0	

Tratamentul pacienților incluşi în studiu a fost stabilit în relație cu rezultatele observațiilor clinice şi ale evaluărilor statistico – matematice (tab. IX).

Prin utilizarea concomitentă a ACO şi a amiodaronei există riscul creşterii efectului anticoagulant datorită interacțiunii celor două tipuri de medicamente. Efectul apare ca urmare a inhibării de către amiodaronă a metabolizării ACO. Astfel amiodarona este incriminată în sensul inhibării enantiomerilor R şi S ai warfarinei prin intermediul citocromului P-450 *in vivo*, dar şi *in vitro* (9,10). Timpul până la apariția incidentelor şi a accidentelor datorate hipocoagulabilității sangvine este variabil şi efectul poate continua câteva săptămâni după identificarea interacțiunii, chiar după întreruperea administrării amiodaronei, datorită timpului de înjumătățire plasmatică prelungit şi variabil al acesteia. Factorii predispozanți pentru apariția acestor efecte ar putea fi şi inducerea de către amiodaronă a tireotoxicozei, care poate creşte clereanceul unor factori ai coagulării dependenți de vitamina K, scăzând, astfel, nivelul coagulabilității sangvine (11,12). Se recomandă controlul mai frecvent al timpului de protrombină, monitorizarea INR-ului şi ajustarea dozei de anticoagulant oral (3,9).

În unele studii (12,13) se recomandă scăderea cu 1/3 până la 1/2 a dozelor de warfarină pentru menținerea unui nivel satisfăcător al activității protrombinei. Existența interacțiunii dintre ACO şi amiodaronă necesită ajustarea dozei cu 32,9% - 70% în cazul warfarinei şi cu 20% - 60% în cel al acenocumarolului.

CONCLUZII

În urma studiului realizat pe un lot de 43 de pacienți, s-a constatat necesitatea ajustării dozei de warfarină cu până la 44% după şapte săptămâni de administrare concomitentă cu amiodaronă. Datorită necesității menținerii amiodaronei în doze de 400, 300, 200, 100mg/dl în terapie concomitent cu warfarina, s-a recomandat scăderea dozei acesteia din urmă cu 40%, 35%, 30% şi respectiv 20%. S-a observat că menținerea dozei de amiodaronă asigură o bună interacțiune între aceasta şi ACO. În cazul utilizării concomitente a ACO şi a amiodaronei s-a constatat modificarea drastică a TQ, INR şi aPTT cu riscul apariției accidentelor hemoragice, urmare a inhibării de către amiodaronă a metabolizării ACO.

În studiile noastre, asocierea statinelor

cu ACO a determinat modificarea coagulabilității, efectul manifestându-se, în special, asupra INR. Acest aspect indică controlul frecvent, la intervale scurte de timp, a TQ, INR şi aPTT, atât în monoterapia cu ACO, cât şi în cazul asocierii statinelor cu ACO, respectiv, în cazul asocierii ACO cu statine şi amiodaronă.

PARAPHARYNGEAL SPACE – HISTORY AND SURGICAL STUDY (Abstract): One area of anatomy, which is a true passage of secrecy, is the anatomy of the potential anatomical spaces. The study of the fascial layers of the head and neck and the potential spaces they make-up is both fascinating and confusing. Much of the confusion is a function of the multiple synonymous terms and classifications that various authors use, and not the basic anatomical description. Their anatomy and communications, to the base of skull and downward to diaphragm, acts like a route through which infection from mouth and throat can reach the superior mediastinum. Conclusions: Understanding the anatomy of the parapharyngeal space is important in making a correct diagnosis and surgical plan for removing tumors in this region. **Key words**: FASCIAL SPACE, PARAPHARYNGEAL SPACE, CLASSIFICATION, SURGICAL APPROACHES.

Spaţiul parafaringian (SPF) reprezintă o zonă anatomică complexă atât prin structură şi organizare, cât şi prin patologie şi de la prima descriere făcută de Burns în 1811, a fost motivul unei mari controverse. Cunoaşterea anatomiei spaţiilor fasciale ale capului şi gâtului constituie suportul înţelegerii etiologiei, diseminării, simptomatologiei şi complicaţiilor variatelor procese patologice ale regiunilor feţei, gâtului şi toracelui (1,4).

Termenul de spaţiu potenţial este utilizat pentru a defini un spațiu ce devine evident prin distensie sau disecție exploratorie, fără distrugerea sau degradarea integrității structurale şi funcţionale a ţesuturilor care participă la delimitarea acestuia (4, 6, 9, 16).

În 1605, pentru prima dată, Francis Bacon a atras atenția asupra „pasajelor" dintre structurile anatomice propriu-zise.

În 1811, BURNS a descris aceste spaţii fasciale pentru prima dată. O importantă clasificare a spațiilor cervicale a fost elaborată de Grodinsky și Holyoke în 1938, când a fost demonstrată și continuitatea acestora cu spațiile mediastinale, până la nivel toracic inferior (1, 4, 5, 9, 12) (fig.1).

Spaţiul parafaringian este constituit, de fapt, atât din spaţiul retrofaringian cât şi din cel laterofaringian.

Trebuie subliniată importanța cunoașterii structurilor anatomice naturale de limitare a SPF, și anume rafeul pterigomandibular (fig.2), tunelul stilomandibular şi mușchiul stiloglos (2, 3, 13, 15)(fig. 3).

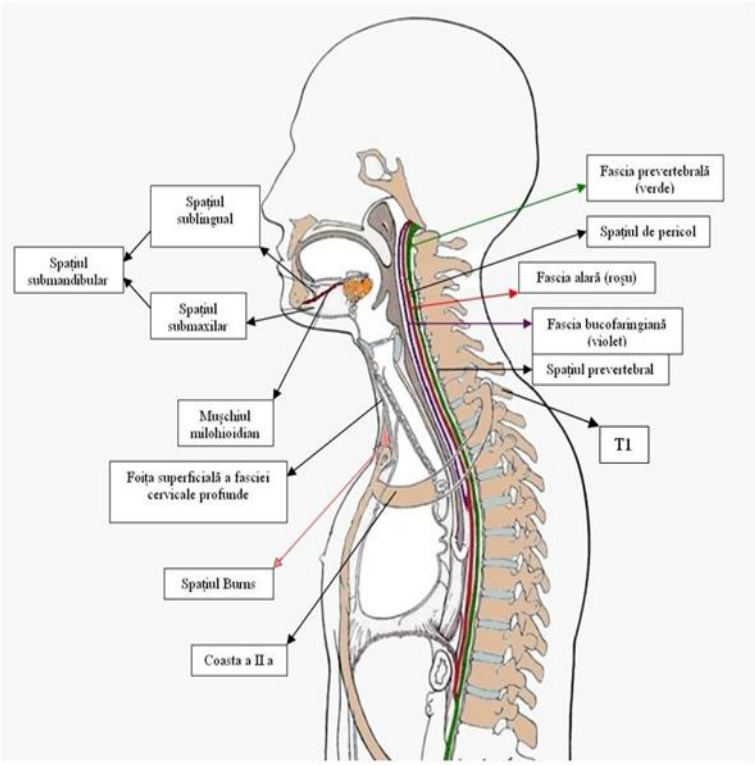

Fig. 1. Spaţii fasciale posterioare – secţiune sagitală

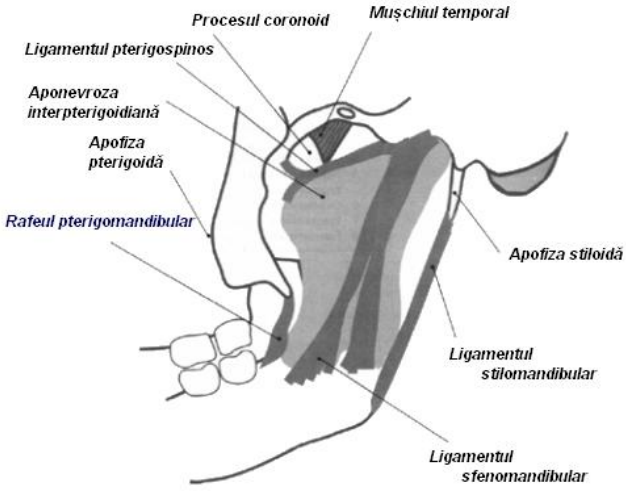

Fig. 2. Rafeul pterigomandibular

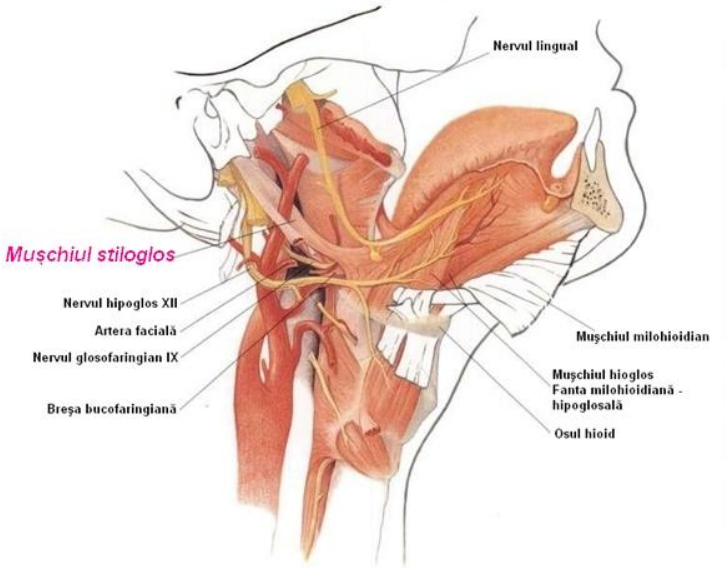

Fig. 3. Muşchiul stiloglos

Scopul acestui articol este de a face o conexiune între compartimentarea acestor spații fasciale și diferitele tipuri de abord chirurgical care pot fi utilizate pentru excizia formațiunilor tumorale parafaringiene.

MATERIAL, METODĂ ŞI TEHNICI DE CERCETARE

Au fost incluși în studiu un număr de 192 de cazuri noi de pacienți cu formațiuni tumorale parafaringiene, internați în Clinica ORL a Spitalului „Sf. Spiridon" Iași, pe o perioadă de 20 ani (1990 -2009).

Toate aceste cazuri au fost evaluate clinic și ca status general, pacienții au fost investigați imagistic și supuși unor intervenții chirurgicale.

ANALIZA STATISTICĂ

Toate datele medicale au fost prelucrate statistic utilizându-se programe specifice, *SPSS 13.0* și Microsoft Office, utilizându-se un grad de încredere de 95%, și obținându-se rezultate cu prag semnificativ $p < 0{,}001$.

REZULTATE

Dezvoltarea deosebită a tehnicilor imagistice au permis specialiștilor radiologi stabilirea unor repere noi de compartimentare a spațiului parafaringian, mai utile chirurgilor otorinolaringologi decât cele clasice, anatomice (8, 10).

Astfel, SPF este împărțit într-un spațiu anterior şi unul posterior de un plan dus de la apofiza stiloidă până la mușchiul tensor al vălului palatin (fig. 4).

Utilizând secțiunile coronale CT sau IRM, fiecare dintre aceste două spații poate fi subdivizat în plan vertical, în 3 etaje (fig. 5):

- Superior (S)
- Mijlociu (M)
- Inferior (I),

Etajele superior (S) şi mijlociu (M), sunt separate printr-un plan situat la nivelul marginii inferioare a mușchiului pterigoidian lateral, iar cel mijlociu (M) și inferior (I) sunt delimitate de un plan situat la nivelul unei linii ce unește marginea inferioară a lamelor laterale ale apofizelor pterigoide.

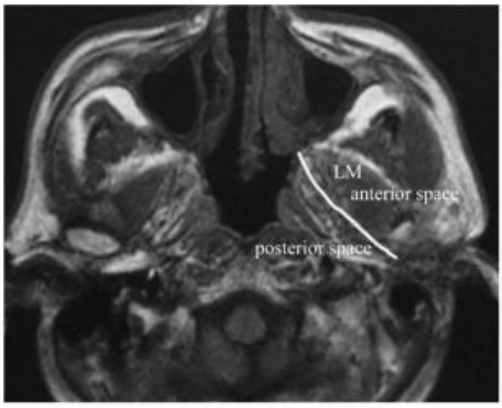

Fig. 4. Compartimentarea anteroposterioară a SPF

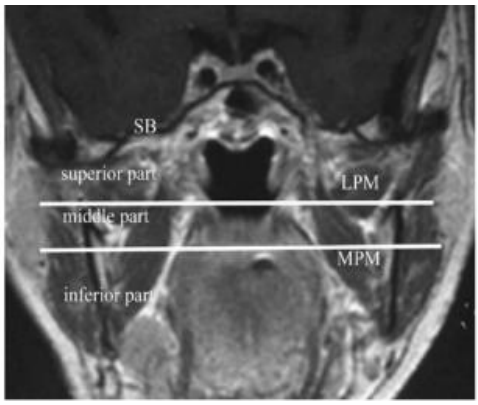

Fig. 5. Compartimentarea în plan vertical a SPF

Astfel se realizează o topogramă cu 6 compartimente, care se va suprapune cu imaginea TC sau IRM a formaţiunii tumorale (tab. I).

TABELUL I

Topograma spaţiului parafaringian

Cadrane ale spaţiului parafaringian	**Posterior P**	**Anterior A**
Superior S	Postero-superior P-S	Antero-superior A-S
Mijlociu M	Mijlociu-posterior M-P	Mijlociu-anterior M-A
Inferior I	Postero-inferior P-I	Antero-inferior A-I

În cadrul acestei topograme, pentru stabilirea localizării formaţiunii tumorale, se va lua în considerare limita superioară a acesteia.

TABELUL II

Tipurile de abord chirurgical preconizat

Cadrane afectate ale spaţiului parafaringian	**Tipul de abord chirurgical preconizat a fi utilizat**
Superior S	-Abordul fosei infratemporale
Mijlociu M	-Abord transoral -Abord transparotidiancu /fără mandibulotomie
Inferior I	-Abord submandibular transcervical
Afectarea simultană a mai multor cadrane ale spaţiului parafaringian	Abord combinat -tr.parotidian+tr.cervical -tr.oral+tr.cervic -tr.oral+tr.parotidian -abord FIT+tr.parotidian

Tipurile de abord utilizate în cazul afectării unuia sau mai multor cadrane ale SPF sunt prezentate în tabelul II.

În cadrul studiului efectuat, tipurile de intervenţii chirurgicală care au fost utilizate sunt cuprinse în tabelul III, fiind reprezentate grafic şi procentele acestor intervenţii în cadrul numărului total de pacienţi la care s-a instituit tratament chirurgical (fig. 6).

TABELUL III

Tipuri de intervenţii chirurgicale	Număr de cazuri	Frecvenţa tipului de intervenţie chirurgicală
Abord transcervical submandibular = Cervicotomie înaltă	144	75%
Abord transoral	18	9,4%
Abord transcervical – transmandibular Mandibulotomie laterală	6	3,1%
Abordul fosei infratemporale	1	0,5%
Abord mixt Cervicotomie + abord transoral	23	12,0%
Total cazuri	192	100%

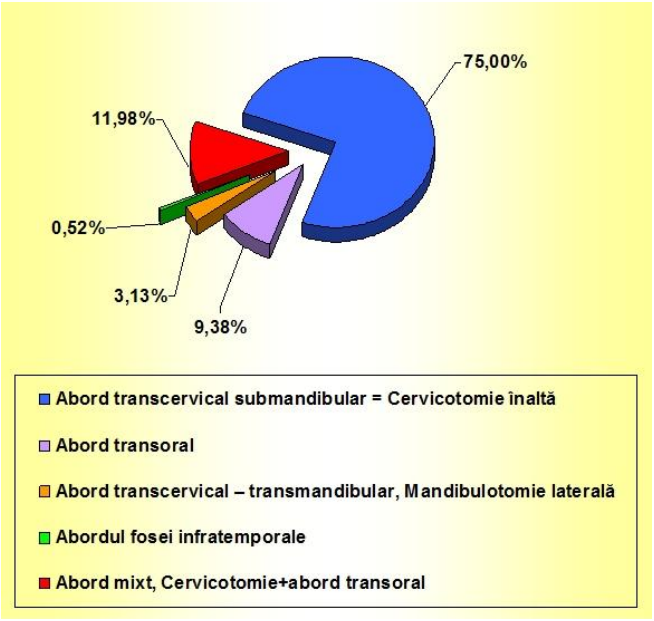

Fig. 6. Tipuri de abord chirurgical utilizat

CONCLUZII

Cunoaşterea anatomiei spaţiilor fasciale cervicale şi a încadrării spaţiului parafaringian între acestea este esenţială în abordul chirurgical al tumorilor parafaringiene.

Cu toate progresele imagisticii realizate până în prezent, abordul tumorilor parafaringiene ridică probleme importante de diagnostic şi mai ales de tratament.

Îmbunătăţirea semnificativă a tehnicilor imagistice au permis un diagnostic mai exact şi în acest mod, creşterea numărului formaţiunilor considerate operabile.

Alegerea căii de abord chirurgical a spaţiului parafaringian trebuie să ţină cont de împărţirea radiologică a acestuia în cele şase compartimente**.**

În cadrul acestei topograme, pentru stabilirea localizării formaţiunii tumorale, se va lua în considerare limita superioară a acesteia.

Managementul eficient al acestor cazuri necesită o colaborare interdisciplinară, a unei echipe formate din chirurgul otorinolaringolog, specialistul radio-imagist, anatomo-patolog, oncolog, neurochirurg, de chirurgie vasculară, plastică şi nu în ultimul rând, psihologul terapeut.

Având în vedere complexitatea zonei pe care se intervine şi probabilitatea survenirii unor situaţii neprevăzute, intempestive şi uneori critice, pacientul trebuie informat cât mai amănunţit asupra tuturor situaţiilor clinice ce pot decurge în timpul şi după actul operator.

2. Clinica O.R.L.

RARE TUMORS OF THE NECK- REPORT OF TWO CASES (Abstract): Of the tumors of the neck some are very uncommon, difficult to diagnose both clinically and paraclinically. Two of the most rare tumors are osteolipoma and soft tissue sarcoma. We present 2 such cases admitted to and operated at the ENT Department of the Iasi „St. Spiridon" Emergency Hospital in the last 5 years, with emphasis on the atypical clinical and imaging features of these tumors. Surgery and histopathological examination were the methods used to make the diagnosis. **Key words**: OSTEOLIPOMA, SOFT TISSUE SARCOMA, RARE TUMORS

Tumorile latero-cervicale reprezintă o entitate destul de des întâlnita în patologia O.R.L. fie ca localizare primară, fie ca diseminare secundară a unui proces neoplazic de cele mai multe ori. Deşi diagnosticul etiologic uneori se poate pune doar pe baza examenului clinic (ex. tumori vasculare), de cele mai multe ori se stabileşte analizând şi datele biologice (hemoleucograma, serologie pentru infecții specifice bacteriene sau virale etc.) şi imagistice (ecografie, CT, RMN) (1).

Cu toată dezvoltarea tehnicii şi specificitatea testelor de laborator pot să apară surprize intraoperatorii şi histopatologice, în special in cazul varietăților cu incidență scăzută.

Raritatea acestor tipuri de tumori face ca un studiu riguros al lor să fie dificil de efectuat, astfel încât principiile terapeutice sunt rezultatul experienței personale sau a unor studii retrospective limitate şi nu se bazează pe studii clinice extinse efectuate pe loturi mari populaționale (2, 3, 4).

PREZENTAREA CAZURILOR

Au fost selectate şi analizate două cazuri internate şi operate în Clinica O.R.L. a Spitalului Clinic de Urgență „Sf. Spiridon" din Iaşi. În aceste cazuri diagnosticul de certitudine preoperator a fost imposibil de stabilit datorita particularităților şi caracterului atipic al formațiunilor tumorale cervicale cât şi a absenței corelațiilor semnificative, clinice sau a modificărilor sugestive ale tabloului biologic.

CAZUL 1

Pacientul M. L. în vârsta de 50 de ani, se internează pentru deformarea regiunii bazicervicale drepte de către o formațiune tumorală de aproximativ 7/6 cm, aparent

bine delimitată, suprafața neregulată, aderenta de planurile profunde muşchiul sternocleidomastoidian (SCM), mobilă pe planurile superficiale (fig. 1).

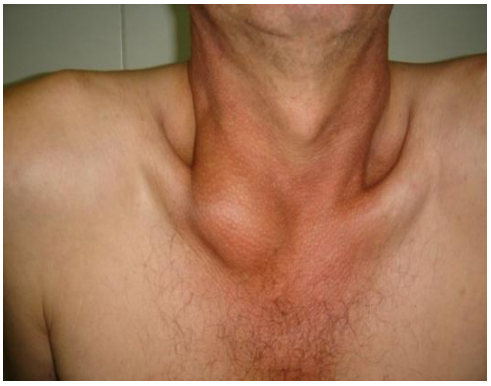

Fig. 1. Formațiune tumorală bazicervicală

Palparea evidențiază consistența elastică a formațiunii care însă devine dură cu caracter osos spre planurile profunde musculare. Pacientul relatează debutul afecțiunii insidios, în urma cu 4-5 ani prin apariția unei formațiuni de mici dimensiuni (1 cm), moale, mobilă, localizată în treimea mijlocie şi anterior de muşchiul SCM, care în timp, coboară, devine dură şi se fixează în regiunea bazicervicală dreaptă, crescând progresiv în dimensiuni. Tabloul biologic este uşor modificat, nesemnificativ (discretă anemie). Panendoscopia nu identifică existența unor zone suspecte care să sugereze o eventuală localizare cervicală, neoplazică secundară.

Ecografia cervicala descrie o formațiune hiperecogenă de 7/4/6 cm (cranio-caudal/orizontal/antero-posterior), fără semnal Doppler, cu efect de masa asupra muşchiului SCM, fără limita de demarcație față de acesta şi fără rapoarte cu pachetul vascular al gâtului.

Se intervine chirurgical şi intraoperator se observa o formațiune cu caracter lipomatos dar consistență dură, osoasă, ce formează un bloc cu fibrele posterioare şi externe din treimea inferioara a muşchiului SCM, excizia largă, completă necesitând şi rezecția parțiala a acestora (fig. 2, 3).

Fig. 2. Aspect intraoperator cu evidențierea zonei dure, aderente de muşchiul SCM

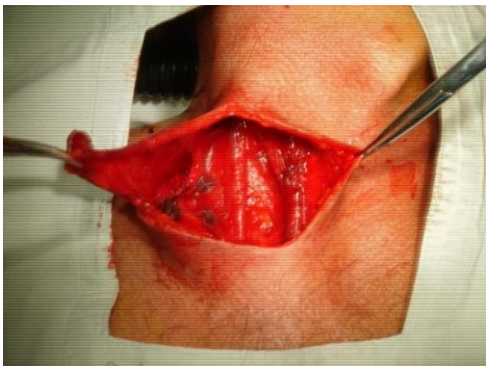

Fig. 3. Aspect postexcizional

Evoluția favorabila permite externarea pacientului la 2 zile postoperator.

Examenul histopatologic descrie o „formațiune tumorală benignă, constituită dintr-un nodul sclerohialin cu metaplazie osoasă ce înglobează fibre musculare striate degenerate sau atrofice şi izolați lobuli de țesut adipos" şi stabileşte diagnosticul de „fibrolipom cu metaplazie osoasă".

CAZUL 2

Pacientul I. F. în vârsta de 50 de ani se internează pentru deformarea regiunii latero-cervicale drepte, în treimea inferioară de către o formațiune tumorala de aproximativ 10/10 centimetri, cu consistență elastică, suprafața regulată, margini bine delimitate, fixată de planurile profunde, ulcerată la tegument pe o suprafață de 7/7 centimetri, uşor sângerânda spontan şi la atingere, cu evoluție în ultimii 3 ani (fig. 4).

Fig. 4. Aspect preoperator

Tabloul biologic şi explorările paraclinice evidențiază un sindrom de citoliză hepatică toxică, cu trombocitopenie şi discretă alterare a coagulării.

Examenul clinic O.R.L. şi panendoscopia nu au evidențiat modificări patologice, formațiunea latero-cervicală fiind considerată astfel o localizare primară.

Ultrasonografia latero-cervicală precizează existența formațiunii tumorale hiperecogene, de 9/8/7 centimetri (cranio-caudal/antero-posterior/orizontal) situată posterior de muşchiul SCM pe care îl invadează şi îl împinge anterior cu efect de masa asupra pachetului vascular al gatului, cu semnal Doppler la interior.

Intraoperator se observă extensia formațiunii retroclaviculare şi se excizează în bloc cu lanțul ganglionar spinal (grupul V), parțial cu fibre din muşchiul SCM, disecându-se cu dificultate de clavicula şi vena subclavie (fig. 5, 6).

Evoluția favorabilă permite externarea la 5 zile postoperator.

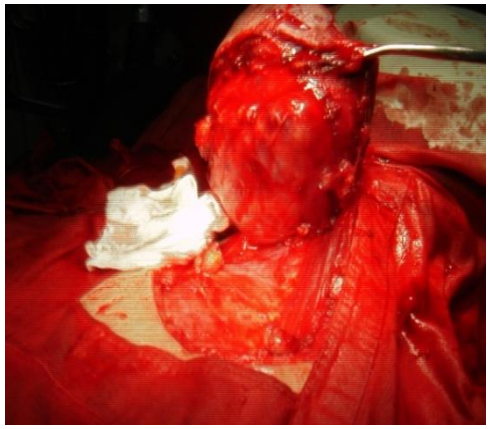

Fig. 5. Aspect intraoperator cu evidențierea muşchilor SCM şi trapez

Fig. 6. Piesa de excizie

Examenul histopatologic evidențiază existența unor „fragmente tumorale cu aspecte de sarcom cu grad înalt de malignitate şi plaje întinse de necroza cu hemoragii". Pentru a se stabili *pattern*-ul tumoral diferențiind un eventual NPNST de un alt sarcom se recomanda reacții imunohistochimice care însă, nu se pot efectua.

DISCUȚII

Deşi aproximativ 13% din tumorile lipomatoase apar la nivelul capului si gatului, majoritatea sunt superficiale şi alcătuite din țesut adipos separat de trabecule fibroase. În cazul în care proporția de țesut fibros crește, vorbim despre fibrolipom.

Uneori se întâmpla ca acest țesut adipos să „infiltreze" structurile musculare din jur (lipom intramuscular) şi, extrem de rar, pot apărea metaplazii osoase sau cartilaginoase (osteolipom, lipom condroid) (1, 2).

Sarcomul este o tumora mezenchimală şi reprezintă sub 1% din totalul neoplaziilor parților moi ale gâtului. (4)

Dificultățile de diagnostic apar datorită faptului că factorii care pledează pentru benignitate coexistă cu caracterele maligne (consistența dură, fixarea pe planurile profunde, evoluția lentă, lipsa unei „tumori primare" şi a modificărilor tabloului biologic).

Nici explorările imagistice, extrem de utile de obicei, în aceste situații nu aduc clarificări asupra tipului tumoral ci doar informații despre invazia de vecinătate.

În acest context, rolul exciziei-biopsie (în limite oncologice) şi a examenului histopatologic rămâne determinant în stabilirea unui diagnostic de certitudine (5).

ALEXITHYMIA AND THE BIG FIVE PERSONALITY TRAITS AS PREDICTORS OF BURNOUT AMONG MEDICAL STUDENTS (Abstract): Professional exhaustion or burnout in health professionals has become a serious problem, as previous studies documented its effects on personal and professional life, such as a lower quality of care, reduced level of patient satisfaction, and problems with patient safety. **Aim:** Our study aimed to assess the influence of several psychological, demographic and academic characteristics on Romanian medical students' levels of burnout. **Material and methods:** Participants (315 students in general medicine) were administered three psychological instruments: Maslach Burnout Inventory, measuring the general level of burnout and its three dimensions: emotional exhaustion, depersonalization and personal accomplishment; Big Five Inventory, evaluating the Big Five Factors (dimensions) of personality: Extraversion, Agreeableness, Conscientiousness, Neuroticism, and Openness; and Toronto Alexithymia Scale, assessing one's difficulties with emotional processing and emotional awareness on three dimensions: difficulty of describing feelings, difficulty of identifying feelings, and externally-oriented thinking. **Results** show that students with higher levels of Neuroticism also report higher levels of Emotional Exhaustion. Also, more extravert, conscientious, open, and less neurotic students experience a greater sense of Personal Accomplishment, while students low on Agreeableness score high on Depersonalization. Associations between the three facets of burnout and demographic and academic variables were also found. **Conclusions:** such psychological profiles of burnout vulnerability among medical students could inform future academic guidance programs designed to prevent burnout at younger stages of medical training. **Keywords**: BURNOUT, PERSONALITY TRAITS, ALEXITHYMIA, MEDICAL STUDENTS.

In order to improve the quality of the medical act, it is important to consider doctors' risk of professional exhaustion, which can hinder their work performance and quality of care towards their patients. The professional activity of doctors has been analyzed from different perspectives: professional, moral, social, ethical but also economic. In recent years, studies have shown that the level of professional exhaustion has effects on personal and professional life (increasing the rate of errors, dropping out of work, substance abuse, increasing suicide attempts). Generally, burnout is also correlated with less free time, risk of experiencing work-home con-

flicts or high level of depression (1).

Burnout in doctors has become a serious problem, many researchers highlighting the relationship between burnout and lower quality of care, reduced level of patient satisfaction, and problems with patient safety. The phenomenon of professional exhaustion in healthcare professionals has also become an economic problem analyzed through investments, costs and profits in health services. A more satisfied physician will provide better medical services and a more compassionate care for patients, which, in return, will reduce the total costs of care (2, 3).

Previous studies on Romanian physicians or other healthcare professionals showed a moderate level of burnout among different specializations but also identified relationships between burnout or job satisfaction and different variables such as socio-demographic variables, alexithymia or personality traits like neuroticism (4-8).

To develop the ability to cope with difficult situations it is necessary to have a good theoretical knowledge acquired during the university curriculum, but also to apply it in practice, both in the framework of the university training stages and during one's professional activity as a doctor. Some studies focusing on medical students from Romanian identified that freshman students are the most depressed and graduating students are the most stressed students, comparing to medical students from other years of study. Also, perceived stress and the level of alexithymia were found to influence the level of depression among medical students, with great impact on academic results (9, 10). The present study aims to assess the influence of several psychological, demographic and academic characteristics on Romanian medical students' levels of burnout.

MATERIAL AND METHODS

Participants

The study developed between June and October 2017. A number of 400 questionnaires were distributed among medical students from General medicine. Students had to complete a document with socio-demographic data and to answer the items of three psychological instruments. A number of 368 questionnaires were returned to the researchers. The exclusion criteria were: incomplete questionnaires and documents returned after 1st of October. After analyzing the returned questionnaires, 315 were finally included in the study.

Instruments

Several demographic and academic data were registered: age, sex, year of study (from one to six year of study), environment (urban/rural), department, admission mark, and information related to the accommodation in the University City (staying with parents or living by themselves in a rented apartment). One item questioned whether at least one of their parents is working abroad.

Three psychological instruments were administered: *Maslach Burnout Inventory* (MBI), *Big Five Inventory* (BFI) and *Toronto Alexithymia Scale* (TAS-20).

MBI (11) has 22 items and it was applied to measure the level of burnout referring to its three general scales: emotional exhaustion (EA), depersonalization (D) and personal accomplishment (PA). Emotional exhaustion evaluates feelings of being emotionally overextended and exhausted by work. Depersonalization refers to the cynic responses, negative attitudes and behaviors at work, in relationship with colleagues or beneficiaries. The Personal achievement scale evaluates one's feelings of competence and successful achievement

at work. A person is professionally exhausted if she/he has a high level of emotional exhaustion and depersonalization and a low level of professional accomplishment.

The second instrument, BFI (12), was used to evaluate the Big Five Factors (dimensions) of personality: Extraversion (E), Agreeableness (A), Conscientiousness (C), Neuroticism (N), and Openness (O). The questionnaire consists of 44 items divided into these five broad domains, each of them rated on a 7-point Likert scale. Neuroticism is characterized by individuals who are frequently worried, tense and fearful. Extraversion measures the tendency to be self-confident, active and sociable. Openness assesses being sensitive, artistic, and imaginative. Agreeableness is captured by aspects as being cooperative, friendly, and generous, while conscientiousness embodies efficiency, competence, and self-discipline.

The third instrument, TAS-20 (13), has three subscales measured using 20 items and a general score. The instrument assesses the difficulties with emotional processing and emotional awareness, respectively, on three domains: difficulty of describing feelings, difficulty of identifying feelings, and externally-oriented thinking. Students rated their answers on a Likert - scale, from 1 (strongly disagree) to 5 (strongly disagree).

Ethical approval

The study was approved by ethical committee of "Grigore T. Popa" University of Medicine and Pharmacy Iasi. Informed consent was delivered together with the documents. Students were informed about the purpose of the study, the confidentiality of collected data and the fact that they could withdraw from the research with no consequences.

Statistical analysis of data

Collected data were analyzed using IBM *SPSS Statistics, version 23*. Means and standard deviations revealed the levels of burnout dimensions among medical students. Pearson and partial correlations were used to investigate the relationships between variables, and hierarchical regression analyses were used to identify the significant predictors of burnout.

RESULTS

Demographic and educational data

All participants to the research (246 females and 69 males) were enrolled in general medicine studies in "Grigore T. Popa" University of Medicine and Pharmacy from Iasi. Their gender distribution corresponds to the gender proportion among the population of students in medicine in the university. Most of the participants are coming from urban areas in the north-eastern part of the country. Almost 40% declared that they are living in the University City or in suburbia. The average age is M = 22 ±3 (ranging from 18 to 27 years). 156 students were registered in preclinical (1st and 2nd) and 159 in clinical years of study (3rd to 6th).

The admission process in the university is based on a final mark (minimum 5 from 10), resulted from a written exam with multiple answers, covering items from different disciplines (biology, chemistry and physics). The mean admission mark for the researched sample is 9.01 (±.9). 59 (18%) of them reported having at least one parent working abroad and more than half (66%) reported living in a rented apartment or in campus.

Participants' demographic and educational characteristics are presented in first table.

TABLE I
Demographic and educational characteristics of the sample

Characteristic	Mean (±SD) N (%)
Age	22 (±3)
Gender – female	246 (74)
Year of study Pre-clinic	156 (47)
Clinic	159 (53)
Department - Iasi	125 (39)
Environment - urban	232 (71)
Admission mark	9.01 (±.9)
Having at least one parent working abroad	59 (18)
Living in a rented apartment or in campus	217 (66)

Psychological results

First, the relations between the psychological factors were examined through Pearson and partial correlations while controlling participants' demographic and educational characteristics (tab.II). Regarding the three dimensions of students' burnout, both types of statistical indexes show significant associations to most of the five factors of the BFI and to two of the alexithymia subscales.

Specifically, the pattern of associations suggests that students' emotional exhaustion is positively associated to their neuroticism, difficulty describing feelings and difficulty identifying feelings, and negatively related to their extraversion, agreeableness, conscientiousness and openness. In other words, the higher the score on neuroticism, the higher students` emotional exhaustion. Also, the more students have difficulties identifying and describing feelings, the higher they score on emotional exhaustion. On the other hand, students low on extraversion, agreeableness, conscientiousness and openness have high scores on emotional exhaustion.

Conversely, Personal Accomplishment emerged as having an opposite pattern of correlations, being positively related to these personality factors and negatively to neuroticism and participants' difficulty in identifying feelings. Thus, students who score high on extraversion, agreeableness, conscientiousness and openness also score high on Personal Accomplishment also. Likewise, students who have higher scores on neuroticism and difficulties in identifying feelings also score low on Personal Accomplishment.

Second, hierarchical regression analyses were used in order to examine for the personality and the alexithymia factors as predictors of burnout, while controlling for the effect of participants' demographic and educational characteristics. Each of the three dimensions of burnout was included as criterion in a different set of regression analyses. In each the demographic and educational characteristics were entered as predictors in Step 1, to assess and to control their effects on the criterion. The five personality factors and the three dimensions of alexithymia were entered in Step 2.

Notes: The upper triangle of the matrix shows Pearson correlation coefficients. The lower triangle of the matrix shows partial correlation coefficients controlling for age, gender, year of study, department, environment, admission mark, parents' migration and accommodation. The matrix's diagonal presents reliability coefficients (Cronbach's α). * p<.05; ** p<.001.

The first regression analysis tested the effect of these factors on Emotional Exhaustion (tab. III). The first model, including only the demographic and educational characteristics, significantly predicted this facet of burnout (p<.01). Two of these characteristics emerged as significant predictors (both ps <.05), specifically year of study, with students in their clinical years reporting less emotional exhaustion, and admission mark, with students who had higher admission marks reporting more intense emotional exhaustion. The second model also significantly predicted this facet of burnout. Two of the variables in this model emerged as significant and positive predictors, namely Neuroticism and Difficulty Identifying Feelings (both ps <.01). Specifically, increases in neuroticism and difficulty

identifying feelings are related with increases in emotional exhaustion. Students reporting high levels of neuroticism and experiencing difficulties identifying feelings tend to also report high levels of emotional exhaustion.

TABLE III

Note: *p <.05; ** p<.01

The second regression analysis included Personal Accomplishment as criterion (tab. IV). The first model, including only the demographic and educational characteristics, significantly predicted this facet of burnout (p<.01). In this set, gender (with females having higher self-assessments on this facet of burnout) and age (with older students having higher means) yielded the significance level as predictors. The second model also significantly predicted Personal Accomplishment. Three personality factors in this model emerged as significant and positive predictors, namely Extraversion, Conscientiousness and Openness, while Neuroticism emerged as a negative predictor of Personal Accomplishment (all ps<.05). Specifically, increases in Extraversion, Conscientiousness and Openness and decreases in Neuroticism are related to increases in Personal Accomplishment. Students who are more extroverted, conscientious, and open, while also scoring low on neuroticism, report feeling accomplished on personal issues.

TABLE IV

Results of hierarchical regression analysis showing amount of variance in Personal Accomplishment accounted for by the five personality factors and the three dimensions of alexithymia (Step 2) while controlling for participants' demographic and educational characteristics

		Step 1	Step 2

	Difficulty Identifying Feelings		.04	
	Externally-Oriented Thinking		.06	
				.17**

Note: *p <.05; ** p<.01

The third regression analysis included Depersonalization as criterion (tab. V). The first model, including only the demographic and educational characteristics, significantly predicted this facet of burnout (p<.01). Three characteristics in this set gender emerged as significant predictors (all ps<.05), specifically gender, environment and migration of parents. Results show that females, students from urban environments and those who have at least one parent abroad have lower self-assessments on this facet of burnout, although this last variable did not yield the significance level in the second step of the analysis, in which the psychological traits were also introduced.

The second model also significantly predicted Depersonalization. Two factors in this model emerged as significant predictors, specifically Agreeableness, which is negatively related to Depersonalization, and Difficulty Identifying Feelings, which emerged as positive predictor of Depersonalization (both ps<.01). More explicitly, increases in Difficulty Identifying Feelings and decreases in Agreeableness are related with increases in Depersonalization. Students who have problems with identifying feelings and are less agreeable tend to report high levels of depersonalization.

TABLE V

DISCUSSION

Burnout affects medical students from the first years (14) to the final years of study (15) and beyond (16), with prevalence rates ranging from 7.0% to 75.2% (17). Furthermore, emotional exhaustion has been shown to be strongly associated with risk of psychiatric morbidity (18). Rates of emotional exhaustion and depersonalization also appear to rise significantly during the graduate's intern year in the public hospital system (18).

Besides involving health professionals to provide psychological support to burnout sufferers, institutional involvement has also become a way to prevent or cure burnout in physicians, which emphases the need to have a deep understanding of the mechanisms and factors that predispose medical personnel to burnout. The aim of our study was to examine the factors of burnout in medical students in a Romanian University. Specifically, we tested whether personality (five factors: Extraversion, Conscientiousness, Openness, Agreeableness, Neuroticism) and alexithymia (Difficulty Describing Feelings, Difficulty Identifying Feelings, Externally-Oriented Thinking) predict burnout (EE, PA, D). We found significant predictors for each of the three burnout dimensions.

Concerning personality factors, the results show that students with higher levels of Neuroticism also report higher levels of EE. Also, more extravert, conscientious,

open, and less neurotic students experience a greater sense of Personal Accomplishment. Last, but not least, students low on Agreeableness score high on Depersonalization.

A study on Japanese nursing students (19) found some correlations supporting the idea of an association between personality factors and burnout. In their research, Neuroticism was positively, and Agreeableness, Conscientiousness, and Extraversion was negatively correlated with Emotional Exhaustion. Extraversion, Conscientiousness, and Agreeableness was negatively, and Neuroticism was positively correlated with Depersonalization. Extraversion, Openness, and Agreeableness was positively, and Neuroticism negatively correlated with PA.

The findings of the present study are consistent with a study by McManus *et al*. (20) who also showed, among others, that Emotional Exhaustion is related to Neuroticism, Personal Accomplishment is related to Extraversion, and Depersonalization is related to Agreeableness, although their study focused on doctors aged 29 and 30. Also, a research of Magnano *et al*. showed that emotional stability negatively predicted exhaustion in health professionals (21).

Our results are also partially supporting those of Cañadas-De la Fuente (22), who focused on nurses. Specifically, these authors found Neuroticism, Agreeableness, and Extraversion to predict Emotional Exhaustion, while we found only Neuroticism to be linked to Emotional Exhaustion. Also, our results showed Agreeableness to be predictive of Depersonalization, while their study also added Neuroticism and Conscientiousness as predictors of this dimension of burnout. Additionally, the authors found all five dimensions to be predictors of PA, while we found support for four of them (Extraversion, Conscientiousness, Openness, and Neuroticism).

Furthermore, in a study by Bakker *et al*. on volunteer counselors, emotional stability predicted EE (23), a relationship that also emerged in our study; emotional stability, Extraversion, and intellect/autonomy predicted Depersonalization (in our study, only agreeableness negatively predicted Depersonalization); Extraversion and emotional stability predicted PA (as in our study).

However, not all studies found a link between the five personality factors and burnout. For example, (18) showed that Extraversion, Agreeableness, and Consciousness did not significantly predict any burnout factor.

Nevertheless, personality seems to relate consistently to all dimensions of burnout. Neuroticism and Extraversion appear to be consistent predictors of burnout (22-25). Some traits of people high in Neuroticism (the predisposition to underestimate self-performance and to respond with strong emotions in stressful situations) seem to lead to symptoms of burnout. The predilection of extraverts to join intense personal interactions may help them prevent burnout. Conscientiousness is associated with a person's perseverance and self-discipline to finish a task and, as a result, that person could also experience higher levels of PA (23). Individuals with high scores on Openness tend to view challenges as opportunities and are inclined to learn and, thus, feel more personally accomplished. Agreeable individuals have lower levels of EE and Depersonalization probably because they are more likely to be caring, nurturing, responsible, and sympathetic (22).

Concerning alexithymia, our results show an association with burnout. Specifically, students reporting higher levels of Difficulties Identifying Feelings also have high levels of Emotional Exhaustion and Depersonalization. The results of other studies point to an association between Alexithymia and burnout in the medical

field. Thus, Bratis *et al.* (26) found a positive correlation with Emotional Exhaustion and Depersonalization and a negative one with personal achievement. Also, Katsifaraki *et al.* (27) found a significant association between Externally Oriented Thinking (a facet of alexithymia) and PA and Depersonalization. Additionally, Popa-Velea *et al.* (28) found alexithymia to have a significant role in the development of burnout syndrome, with a prevalence of 6.02% in a sample of Romanian medical students. Researchers should focus on the impact of alexithymia and its possible connections with various psychological problems and its relationship with stress and depression during medical studies (29).

This study has some limitations that should be taken into consideration when interpreting the results. A cross-sectional survey design was utilized, and longitudinal data will be necessary to establish causality among the variables considered. Also, it included a relatively small number of participants and the context was restricted to a university, thus the generalizability of the statistically significant associations that emerged is limited. However, this study offers some valuable insights into burnout among medical students.

CONCLUSIONS

Overall, this study adds to the identification of personality factors and alexithymia associated with burnout among medical students in Romania and confirms the role they play in the experience of burnout. Our findings highlight the need for academic guidance programs to prevent burnout at younger stages of medical training. We could also take into consideration personality profiling with the aim of identifying resources to prevent burnout among medical students with vulnerable personality traits.

ASSESSMENT OF SOME LABORATORY, IMAGING AND ANATOMICAL-PATHOLOGICAL INVESTIGATIONS ON A LOT OF 104 PATIENTS DIAGNOSED WITH BREAST CANCER AND APPEAR IN THE LIST OF FAMILY DOCTOR FROM THE CITY OF IASI (Abstract) : **The aim** of study was to assess some investigations in female patients with benign and malignant breast diseases. **Material and methods** : The study was performed on a sample of 104 patients registered with breast tumors, at family physicians' offices from Iasi, Romania. **Results :** Impaired glucose tolerance was associated with 34.2% of patient with breast tumors, and hypercholesterolemia with 25.9% of them. Anatomo-pathological assessments included aspiration puncture and biopsy, extemporaneous biopsy, and paraffin-embedded exam. Invasive carcinoma was the most frequent histo-pathological type (42.1%). **Conclusions** Further investigations on tumor markers are needed in all patients with in situ neoplasia and breast carcinomas. **Key words** : BENIGN BREAST DISEASE, BREAST CANCER, BIOCHEMICAL AND HISTO-PATHOLOGICAL EXAMINATIONS, RISK FACTORS

La nivel mondial, cancerul mamar este principala cauză de deces la femeile de peste 40 de ani, cu o rată a incidenţei de două ori mai mare decât cea a cancerului de col uterin şi colorectal. În 2008, maladia a cauzat aprox. 800.000 decese mondial – 8% din toate decesele prin cancer şi aprox. 1% din decese prin toate cauzele (1,2). Se apreciază că între 6 şi 10% din totalul femeilor vor dezvolta boala cancer de sân şi 1 din 4 femei suferinde de cancer are, drept localizare a bolii, glanda mamară.

În ultimii ani s-a remarcat o scădere a ratei mortalităţii prin cancer mamar, ajungându-se la aproximativ 25%ooo. Această tendinţă se poate datora diagnosticării cancerului mamar în stadii din ce în ce mai precoce - prin metode de screening aplicate populaţional, în special prin mamografie (3,4,5).

MATERIAL ŞI METODĂ

Studiul a fost realizat pe un lot de 104 paciente diagnosticate cu formaţiuni mamare şi înscrise la cabinete individuale de medicină de familie, din Iaşi. Au fost luate în consideraţie investigaţiile de laborator (glicemie, colesterol total), imagistice (ecografia mamară, mamografia) şi anatomopatologice (examenul citologic al frotiului obţinut prin puncţie mamară, biopsia extemporanee). Datele au fost culese retrospectiv din fişa individuală a fiecărei paciente şi ulterior prelucrate statistic.

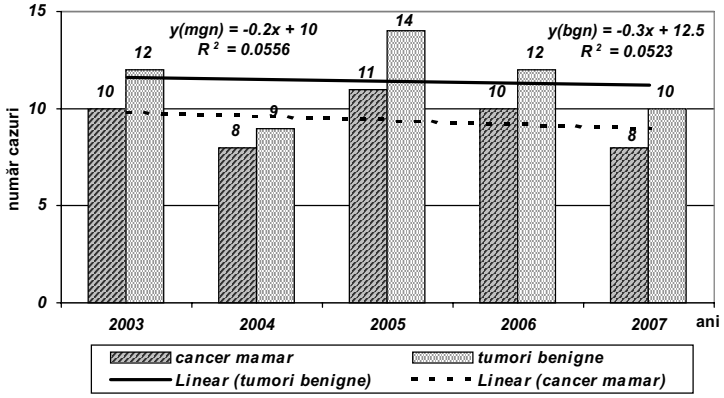

Fig. 1. Repartiţia anuală a numărului de cazuri de tumori mamare

REZULTATE ŞI DISCUŢII

1. Distribuţia anuală a cazurilor de tumori mamare, atât maligne (44,2% din total), cât şi benigne (55,8%), arată o tendinţă descrescătoare, fapt care poate fi explicat prin creşterea adresabilităţii la medicul de familie, dar şi îmbunătăţirea mijloacelor de diagnostic (fig. 1).

Derularea programelor de screening în tumorile mamare, în ultima perioadă, a conştientizat populaţia feminină de riscul apariţiei unei tumori mamare, crescând astfel şi adresabilitatea femeilor la medicul de familie, în vederea aplicării unei metode de screening (5, 6, 7).

2. Repartiţia pe grupuri de vârstă. Cele mai multe cazuri de tumori benigne (25,0%) au fost înregistrate la grupul 36-45 ani, iar de tumori maligne (25,9%, $p > 0,05$), la femeile între 45-65 ani, grup cu numeroşi factori de risc, cumulaţi pe parcursul existenţei (fig. 2).

3. Repartiţia pe categorii profesionale a arătat că, în lotul de paciente luat în studiu, cele mai multe cazuri au fost întâlnite la femeile încă în activitate profesională şi la profesii care ar cumula factori de risc precum sedentarismul (funcţionare), stresul ocupaţional (cadre medicale şi didactice), pauciparitatea (femei angajate – 39 cazuri *versus* casnice – 3 cazuri) (fig. 3).

4. Examene biochimice. Evoluţia de lungă durată a diabetului zaharat, asociată cu modificări la nivelul glandei mamare, poate fi luată în consideraţie ca factor etiopatogenic în tumorile sânului. În lotul studiat, 34,2% dintre femei au prezentat *scăderea toleranţei la glucoză*, iar 11,5% diabet zaharat tip II. S-a constatat că în 27 cazuri (25,9%), *hipercolesterolemia* a fost asociată cu cancerul de sân (fig. 4). Această asociere poate fi explicată prin factori de risc comuni (consumul crescut de grăsimi animale, sedentarismul, stresul). Trebuie luat în consideraţie faptul că, biochimic, colesterolul este precursorul hormonilor sexuali, iar o creştere a acestuia conduce la dezechilibre ale balanţei estrogeni-progesteron şi, deci, la hiperestrogenemie, factor de risc important în etiopatogenia tumorală mamară (3,4,9). Corelaţia între categoria profesională (angajate / neangajate) şi hipercolesterolemie nu a fost găsită semnificativă statistic ($p > 0,05$, coeficient de corelaţie 0,36; dispersia între cele două teste – 12,3%); un studiu pe loturi mai mari ar putea conduce la rezultate valide fiziopatologic.

5. Unele explorări paraclinice. Pacientele luate în studiu au beneficiat de ecografie mamară (23,1% paciente diagnosticate cu cancer mamar) şi mamografie (44,2%). La

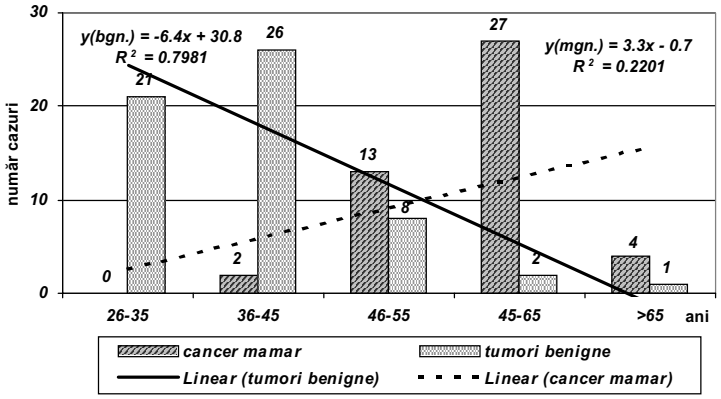

Fig. 2. Repartiţia pe grupuri de vârstă

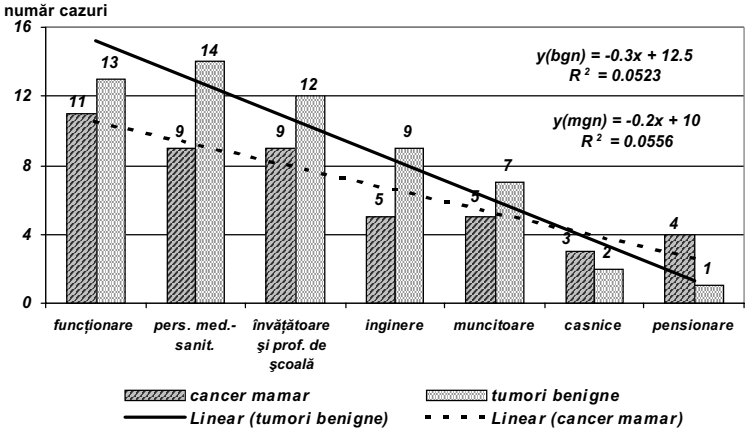

Fig. 3. Repartiţia pe categorii ocupaţionale

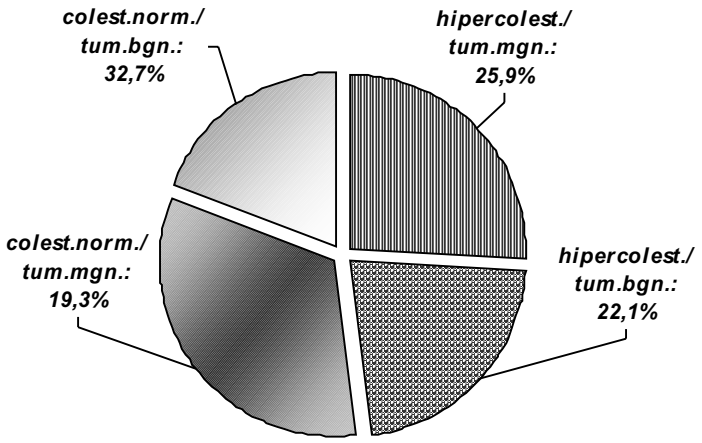

Fig. 4. Relaţia între nivelul colesterolemiei şi tipul tumoral

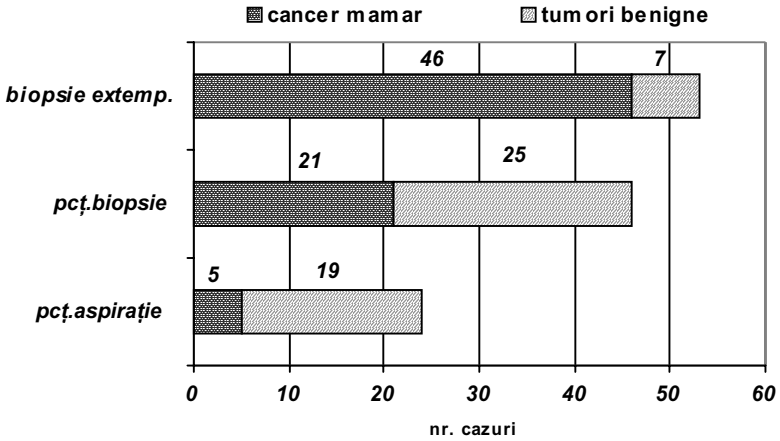

Fig. 5. Rezultatele puncţiilor şi biopsiei

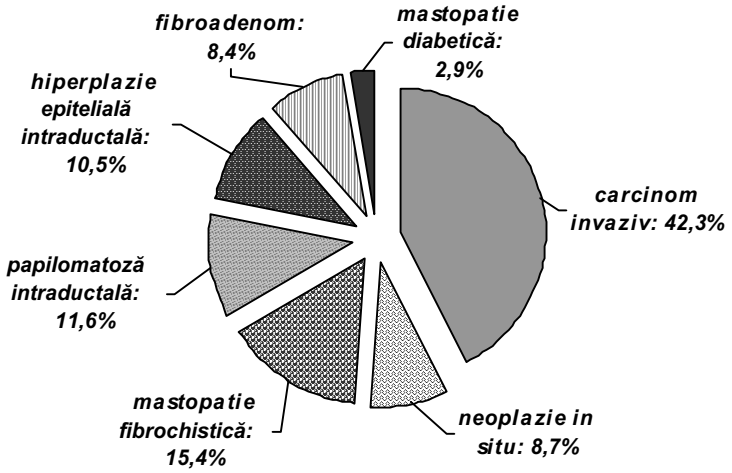

Fig. 6. Rezultatele examenului anatomopatologic

biopsia extemporanee, au fost decelate 46 (44,2%) cazuri de tumori mamare maligne şi doar 7 (6,7%) benigne. *Puncţia biopsie* a fost utilizată în special pentru tumorile benigne (24,1%), la fel ca şi puncţia aspiraţie (18,2%) (fig. 5).

Examenul anatomopatologic (extemporaneu şi / sau după includerea la parafină) a evidenţiat (din buletinele anatomo-patologice au fost selectate unele elemente mai importante de diagnostic) că tipul histopatologic de carcinom invaziv a fost prezent în 44 cazuri (42,1%) (fig. 6), rezultate similare cu cele publicate în studii de anatomie patologică a tumorilor de sân (3, 4, 8, 9, 10).

CONCLUZII

Studiul descriptiv efectuat a cuprins 104 paciente aflate în listele medicilor de familie din cabinete din Iaşi, diagnosticate cu tumori mamare. Distribuţia anuală a cazurilor de tumori mamare, atât maligne, cât şi benigne, arată faptul că, în ultimul deceniu, a crescut numărul de cazuri diagnosticate cu cancer de sân. Repartiţia pe grupuri de vârstă a cazurilor de tumori maligne arată faptul că

cele mai multe au fost diagnosticate la grupul de vârstă 45-65 ani, grup cu numeroşi factori de risc pentru cancerul de sân.

Ca investigaţii paraclinice au fost menţionate : evaluarea glicemiei, a colesterolului total seric, evaluări imagistice prin ecografie mamară şi mamografie, evaluări anatomo-patologice prin puncţie aspiraţie, biopsie extemporanee şi examenul la parafină. Carcinomul invaziv a fost cea mai frecventă forma histopatologică întâlnită în lotul studiat.

De asemenea, evaluarea prin identificarea markerilor tumorali este necesară la toate pacientele cu neoplazie *in situ* şi cancer mamar.

THE INFLUENCE OF PREMATURE UNILATERAL LOSS OF MANDIBULAR DECIDUOUS MOLARS ON CONDYLAR AND RAMUS VERTICAL SYMMETRY

E. R. Cernei, Loredana Golovcencu, Daniela Anistoroaei*, Georgeta Zegan

THE INFLUENCE OF PREMATURE UNILATERAL LOSS OF MANDIBULAR DECIDUOUS MOLARS ON CONDYLAR AND RAMUS VERTICAL SYMMETRY (Abstract): **Aim**: This study evaluates the influence of premature unilateral loss of mandibular deciduous molars on condylar and ramus vertical symmetry, on digital orthopantograms of a sample of Romanian patients. **Material and methods:** The retrospective study was performed on 200 patients (128 boys and 72 girls), between 6-9 years old, during 2010-2015, in the Clinic of Pediatric Dentistry Ambulatory of the "Sf. Spiridon" County Clinical Emergency Hospital from Iasi, Romania. The digitally measurements were made with Planmeca Romexis Viewer 3.0.1®, according method to a known method. **Results:** Statistically significant differences were found between the control group (without loss of deciduous molars) and the study group (with premature unilateral loss of mandibular deciduous molars) for mean values of the condylar asymmetry index (p=0.000), which were over 5-7%, indicating the condylar asymmetry. **Conclusions:** The premature unilateral loss of the mandibular deciduous molars is a risk factor for the condylar symmetry. **Keywords**: PREMATURE UNILATERAL LOSS, MANDIBULAR DECIDUOUS MOLARS, DIGITAL ORTHOPANTOGRAMS, CONDYLAR ASYMMETRY.

The premature loss of mandibular deciduous teeth is a consequence of untreated carious lesions and lead to three-dimensional disorders of the dental arch and occlusion. Thus, there may appear local modifications (delays or accelerations of permanent teeth eruptions), intra-arch modifications (migration of permanent teeth with loss of space, arch shrinking and crowding) and inter-arch modifications (super-eruptions of the opposite teeth, crossbites, premature contacts and occlusal interferences) (1, 2, 3 and 4).

During the first decade of life, the mandibular condyles become less vascularized and the major morphological changes are completed. Intra-articular modifications in mixed dentition period are unclear. Some studies have shown that dental occlusion is adjusted very rapidly in growing children and there may be no influence on condylar morphology or temporo-mandibular joint (5, 6). However, a recent study reported that the unilateral loss of the mandibular permanent first molar before the age of 12 would have an influence on the mandibular

condylar symmetry, but without clinical importance (7).

Recently, studies of condylar asymmetry associated with malocclusions have increased (8, 9, 10), but no study has been conducted to evaluate the association with premature unilateral loss of mandibular deciduous molar. The objective of present study is to investigate whether the premature unilateral loss of mandibular deciduous molars has an influence on the symmetry of the condyles and the ramus vertical of the mandible. The purpose of our study is to establish the effects of premature unilateral loss of mandibular deciduous molars on the height of the condyles and the vertical ramus of mandible, using the method described by Habets *et al.* (11), on digital orthopantograms (OPGs) of a sample of Romanian patients with early mixed dentition.

MATERIAL AND METHODS

The retrospective study was carried out on the digital OPGs of 200 patients aged between 6-9 years, who asked for paedodontic and orthodontic treatment during 2010-2015 period, in the Clinic of Pediatric Dentistry Ambulatory of the "Sf. Spiridon" County Clinical Emergency Hospital in Iasi, Romania. The informed consent was acquired from all patients or their parents.

The patients included in this study had early mixed dentition and no carious lesions on permanent incisors and first molars and no previous orthodontic treatment. Patients with syndromes, cranio-facial or neuro-muscular malformations, facial asymmetries and dental fillings were excluded.

The patients were divided into two groups: 64 (32%) patients without deciduous teeth absent in the lateral area and no signs or symptoms of temporo-mandibular dysfunction (TMD), as control group; 136 (68%) patients with at least one premature loss of a mandibular deciduous molar, as study group. The study group was divided into subgroups, depending on the premature unilateral loss of mandibular deciduous molars: subgroup 1 consisting of 24 (12%) patients with the premature loss of mandibular deciduous second molar on the right side; subgroup 2 consisting of 18 (9%) patients with the premature loss of mandibular deciduous first molar on the right side; subgroup 3 consisting of 14 (7%) patients with the premature loss of mandibular deciduous first and second molars on the right side; subgroup 4 consisting of 22 (11%) patients with the premature loss of mandibular deciduous second molar on the left side; subgroup 5 consisting of 44 (22%) patients with the premature loss of mandibular deciduous first molar on the left side; subgroup 6 consisting of 14 (7%) patients with the premature loss of mandibular deciduous first and second molars on the left side.

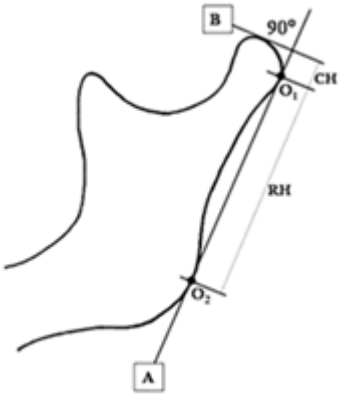
*Measurements made on digital OPGs***.** At the moment of exposure, the head of patient were positioned on to the chin support with relaxed lips and with the Frankfort plane parallel with the horizontal plane, according to Azevedo *et al*. (12). All selected OPGs were made within a single radiological center, using the radiological device PlanmecaProMax®2D, to be saved afterwards in electronic format. Digital OPGs which presented the bilateral radiological anatomical features of the jaws, including the head of the condylar mandibular and no artifacts were included.

The measurements were made digitally by a single examiner, using the Planmeca

Romexis Viewer 3.0.1® software, after the proper calibration. All measurements were made in millimeters (mm), according method described by Habets *et al.* (11) (fig. 1). For the calculation of the condylar asymmetry index (CAI), the ramus vertical asymmetry index (RAI) and the condyle and ramus vertical asymmetry index (CRAI), the formulas suggested by the same authors ware used:

$$CAI = \frac{CHr - CHl}{CHr + CHl} \times 100; \quad RAI = \frac{RHr - RHl}{RHr + RHl} \times 100; \quad CRAI = \frac{CRHr - CRHl}{CRHr + CRHl} \times 100;$$

where CHr/l – condylar height right/left;
RHr/l– ramus height right/left;
CRHr/l(CHr/l+RHr/l) –condylar and ramus height right/left.



O_1– the most lateral point on the mandibular condyle
O_2 – the most lateral point on the mandibular ramus vertical
line A – tangent to the most lateral points of the mandibular condyle (O_1) and ramus vertical (O_2)
line B – perpendicular to line A, tangential to the highest point of the mandibular condyle
CH – condylar height, that correspond to the distance measured between the line B to the point O_1
RH – ramus height, that correspond to the distance measured between the points O_1 and O_2

Fig. 1. The measurement method described by Habets *et al*. (11)

*Statistical analysis***.** The software used for the data analysis was *SPSS 20.0* (Chicago, Illinois, USA), for Windows. We calculated the frequency and descriptive parameters – mean value, standard error, standard deviation (SD), minimum and maximum value, for each group. The *t*-paired test was used to find statistically significant differences between the right and left sides for the measurements of the CH, RHand CRH in the control group and the subgroups. The *t*-student test was used to verify whether there are significant differences of the calculated indices (CAI, RAI and CRAI) for the groups and subgroups, since their values comply with the normal law. The normal law was checked with the Kolmogorov-Smirnov test.

In order to identify the possible errors during measurements, two weeks after the first measurements, 30 OPGs were selected for which the measurements were repeated by the same author. The error values as per Dahlberg's method (13) were within acceptable limits and the difference between the first and second measurements was insignificant. The difference between the two measurements was tested for signifi-

cance with *t*-paired test and no statistically significant difference was identified between the two measurements ($p>0.05$).

RESULTS

Out of the 200 analyzed OPGs, 128 (64%) belong to boys and 72 (36%) to girls, with the mean age of 7.53±0.98 years (tab. I).

No statistically significant difference was founded between the right and left side of mean values measurements of the heights of mandibular condyle and ramus vertical in the control group and subgroups with premature unilateral loss of mandibular deciduous molars on the right/left side ($p>0.05$), but the mean values are more decreased on the side with premature lost molars than on the normal side (tab. II).

TABLE I

Characteristics of patients' groups

Groups	Sex	N	Age	
			Mean	SD

DISCUSSION

Although the computed tomography (CT) and cone beam computed tomography (CBCT) have progressively become a top method used in many comparative studies (14, 15, 16), the OPG still represents a screening method for children aged 6-12 years (17). OPGs have been used in many studies which analyzed mandibular (18, 19) and condylar asymmetries (8, 9, 10), as a risk factor for TMD. Kambylafkas *et al.* (20) found the OPG was not very sensitive in the diagnosis of height total mandibular asymmetries, suggesting can be used to evaluate the posterior mandibular vertical asymmetry. Reproducibility of vertical and angular measurements on OPG is acceptable, if during exposure the patient's head is correctly positioned in the horizontal plane (21). The impossibility of positioning the head's mid-sagittal plane on the median rotation line of the device will lead to a distorted image on the horizontal plane (8, 20). Fuentes *et al.* (21) reported that Habets' technique did not show any statistically significant differences in the x-rays at 5° and 10° horizontal angles compared to the 0º angle.

The specialized software used in this study had the advantage of accurately iden-

tifying bone structures, radiographic landmarks, and measurements, due to the zoom and image contrast editing options. The correctness of the digital measurements was verified by the *t*-paired test.

We used the method of Habets *et al*. (11) to measure the height of condyles and the ramus vertical (CH, RH, CRH) on right/left side and to calculate asymmetry indices (CAI, RAI, CRAI), because was shown the reliability (22), although there is no consensus with respect to the utility of the different techniques used to measure mandibular asymmetries (18). Comparison of the mean values of these right/left measurements was not statistically significant in the studied groups, but more decreased average values were observed in the side of the lost mandibular deciduous molars. For control group in importance the variability of the mandibular constitutional, the masticator type, the mandibular dynamics typology and the differentiated preferences of children regarding food consistency. The loss of the unilateral occlusal support of mandibular deciduous molars leads to a displacement upwards-downwards of the condyle in the glenoid fossa, lead progressively to a different growth of the right condyle compared to the left one (23).

By the comparison the values of the calculated indices, we found significant differences in the mean values of the condylar asymmetry index (CAI) between the groups, which shows that the premature unilateral loss of mandibular deciduous molars determines an asymmetry of mandibular condyles. Also, we found significant differences for the condylar asymmetry index between the control group and subgroups with the premature loss of mandibular deciduous second molar on the right/left side and with premature loss of mandibular deciduous first and second molars on the right/left side. These results are the most important of our research and are not found in previous studies. Condylar asymmetry determined by comparing the vertical condylar height between the left and right condyle can be considered a risk factor for the development of a TMD (24, 25).

According to Habets *et al*. (11) a relation of asymmetry index (CAI, RAI, CRAI) of 3% appear to a change of up to 1cm of the position of the head during the OPG expose (25). Thus, the asymmetry index with an exceeded value of 3% should be considered as being vertical asymmetry (23). In the control group, the mean values of the condyle asymmetry index were over 3%, probably due to occlusal disorders. These results are comparable with those obtained in other studies performed on patients with normal occlusion (8, 9). In the study group the mean values of the condyle asymmetry index (over 5-7%) were different from the results obtained in other studies performed on patients with malocclusions (8, 15).

The mean values of the ramus vertical asymmetry index (RAI) and the condyle and ramus vertical asymmetry index (CRAI) were not statistically significant, indicating that symmetry was not affected by the unilateral absence of mandibular deciduous molars.

Similar future studies may extend to premature unilateral loss of maxillary deciduous molars or use of CT and CBCT measurements. Clinical implications of premature unilateral loss of deciduous molars may be reversible, if intervening on time with interceptive treatment for dental arch and occlusion rehabilitation.

CONCLUSIONS

Our research has shown that there may be other new risk factors for the condylar

symmetry compared to previous studies, clinical and therapeutic significance for children and practitioners. The premature unilateral loss of the mandibular deciduous molars can influence the symmetry of condyles. The mean values of the condyle asymmetry index were statistically significantly different between the control group and the study group with premature unilateral loss of deciduous mandibular molars, and the percentages were over 3% to be interpreted as condylar asymmetry.

NEWS

IT'S ALL IN THE EYES: ASSOCIATION BETWEEN RETINAL NERVE FIBER LAYER THICKNESS AND RISK OF COGNITIVE DECLINE

The global burden of people with neurodegenerative pathology is increasing and this is why there is a great desire to discover the perfect screening tool for cognitive decline. A group of researchers used the retina as "mirror image" of the central nervous system and conducted a study on 32 038 UK residents aged 40 to 69 who underwent cognitive testing and optical coherence tomography imaging. They discovered that participants with a thinner retinal nerve fiber layer (RNFL) were more likely to fail at least 1 or more of the 4 cognitive tests compared to those who had a RNFL of at least 60.2μm. Furthermore, a repeated assessment of 1251 participants after 3 years showed that those with a thinner baseline RNFL did worse on at least 1 follow up cognitive test. This is a very exciting study because it opens new directions for research in the prevention and treatment of dementia and it is the largest one of this kind so far. (Ko F, Muthy ZA, Gallacher J, *et al*. Association of Retinal Nerve Fiber Layer Thinning with Current and Future Cognitive Decline: A Study Using Optical Coherence Tomography. *JAMA Neurol* 2018; 75(10): 1198-1205).

IMMUNOCHEMICAL ASSESSMENT OF p16 AND HPV L1 CAPSID PROTEIN IN CERVICAL INTRAEPITHELIAL LESIONS (Abstract): The behavior of the cervical squamous intraepithelial lesions cannot be predicted, many of them, particularly of the low grade type, may disappear without treatment. Invasive cervical carcinoma occurs in approximately 10% of the intraepithelial precursor lesions, being strongly associated with HPV infection. The aim of this study was to make a comparative assessment between immunohistochemical and immunocytochemical expression of p16 and L1 HPV capsid protein respectively, in low grade and high grade cervical squamous intraepithelial lesions. **Material and method**: The study involved 20 patients with cytological diagnosis of LSIL/CIN1 (low grade squamous intraepithelial lesion/cervical intraepithelial neoplasia) and HSIL (CIN2 and CIN3) (high grade squamous intraepithelial lesion), which underwent a subsequent cervical biopsy. The conventional smears were evaluated for the immunoexpression of L1HPV protein and the corresponding biopsies for the immunoexpression of p16. **Results**: The HPV L1 capsid protein was expressed in 46% of LSIL and 24% of HSIL. P16 was positive in 68% of LSIL, 84% of CIN2 and 100% of CIN3. The correlative analysis of p16 status and protein L1HPV expression can be very useful in the assessment of progression risk of cervical squamous intraepithelial lesions. **Key words**: HPV, L1 CAPSID PROTEIN, p16, LSIL, HSIL

It is now accepted that invasive cervical squamous carcinomas and the correspondent precursor lesions are determined by specific types of Human papillomavirus (HPV), especially high oncogenic risk types, which infect the anogenital tract. At present, the proportion of cervical carcinoma attributed to HPV infection is estimated to 99%. Many observations have indicated the importance of immune response in HPV infection. Antibodies against capsid proteins of different types of HPV have been previously studied, using fusion bacterial proteins or chemically synthesized peptides (1,2). As an essential condition of these studies, HPV infecting type has to be detected. Until recently, the detection of HPV type in a certain tissue was performed by hybridization arrays with nucleic acids. Polymerase chain reaction (PCR) was developed as a more specific and sensitive method of HPV DNA amplification, used either for general detection or for the HPV typing, particularly in genital infections. The issue of quantification is the main limit of the procedure, the distinction between latent subclinical infection and evident clinical lesions being difficult. As an alternative to

hybridization and PCR, the immunologic detection of viral capsid antigens can be used for the diagnostic of productive HPV infections.

The tumor suppressor protein p16 is a cyclin-dependent kinase inhibitor that regulates transition from the G1 to the S phase of the cell cycle (3,4).

The high immunoexpression of the p16 was previously reported to be characteristic for dysplastic and neoplastic epithelium of the cervix (5,6,7). P16 overexpression slows down the cell cycle by inactivating the cyclin--dependent kinases that phosphorylate retinoblastoma protein (pRb) (8,9). The viral oncogenes E6 and E7 of HPV, whose expression is associated with malignant transformation of the cervical epithelial cells (10,11), have the ability to bind and inactivate pRb which, in turn, influence the p16 expression in cervical intraepithelial squamous lesions (SIL) (12). Recent studies have proposed that p16 is a useful marker for HR (high risk)-HPV type related cervical neoplasia (9,13) and for predicting SIL progression (14,15).

The behavior of the cervical squamous intraepithelial lesions cannot be predicted, many of them, particularly of the low grade type, may disappear without treatment. Invasive cervical carcinoma occurs in approximately 10% of the intraepithelial precursor lesions, being strongly associated with HPV infection (16,17,18). The aim of this study was to make a comparative assessment between immunohistochemical and immunocytochemical expression of p16 and L1 HPV capsid protein respectively, in low grade and high grade cervical squamous intraepithelial lesions in order to determine, by clinico-morphological correlations, their practical applicability in patients diagnosis and follow-up.

MATERIALS AND METHODS

Twenty patients were included in our study, 10 cases with cytological diagnosis of LSIL (low grade squamous intraepithelial lesion) and 10 cases with HSIL (high grade squamous intraepithelial lesion), which underwent a subsequent cervical biopsy. The cervico-vaginal smears were fixed and stained using Papanicolaou method. The conventional smears were evaluated for the immunoexpression of L1HPV capsid protein and the corresponding biopsies for the immunoexpression of p16.

After Pap cytodiagnosis, the cervico-vaginal smears were used to detect HPV L1 capsid protein by immunocytochemistry, using the monoclonal antibodies (Cytoactiv HPV L1 High Risk Set REF SCA0850, Cytoimmun Diagnostics GmbH) in a standardized protocol. Epithelial cells with positive nuclear staining were scored as positive, considering one stained nucleus enough for scoring.

The cervical biopsies were investigated by routine histopathological exam and by immunohistochemistry, using p16-D25 antibodies. Collected tissues were fixed for 24 hours in buffered formalin and processed for paraffin embedding. Serial sections of 4-5 μm were dewaxed and stained with Hematoxylin-Eosin. After performing the standard histopathologic exam, supplementary sections were used for immunohistochemical exam. Heat-induced epitope retrieval technique was performed using Target Retrieval Solution pH 6 (code S1700, DAKO, Denmark). After blocking the endogenous peroxidase and non-specific binding, the sections were incubated with one of the primary antibodies, anti-p16 mouse monoclonal antibody (clone D25, code sc-81613, Santa Cruz, USA), dilution range 1 : 100. The immune reaction was amplified using the appropriate secondary antibody and the Streptavidin–Biotin– Peroxidase HRP complex (code K5001, DAKO, Denmark). Sections were then developed using 3,3'-diaminobenzidine tetrahydrocloride chromogen (DAB) (code K5001, DAKO, Denmark), under microscope control. The sections were finally counterstained with Mayer's Hematoxylin. Negative control was also performed.

TABLE I
p16 Immunohistochemical score

Score	p16
0	none
1	Weak (<25% immunopositivity)
2	Moderate (25-75% immunopositivity)
3	Intense (75-100% immunopositivity)

The quality control represented by external and internal negative and positive controls was necessary to monitor the accuracy of tissue processing, staining procedures and reagents effectiveness. The primary antibody specificity sought to be assesed by their negative controls.

Protein p16 was scored based upon the estimated proportion of immunopositive cells (table I).

RESULTS

In our study, the histopathological diagnoses were consistent with the cytodiagnoses, as follows : 10 cases with LSIL (CIN1) and 10 cases with HSIL (4 cases CIN2 and 6 cases CIN3).

HPV infection was morphologically confirmed by the presence of cytopatic HPV effect (koilocytes) in the smears and biopsies.

The p16 staining pattern was predominantly nuclear with occasional cytoplasmic positivity. Most cases presented heterogeneity of staining with positive cells admixed with negative cells.

From all cervical biopsies, p16 was positive in 68% of LSIL, 84% of CIN2 and 100% of CIN3. The proportion of biopsies with intense immunoexpression of p16 increased with the severity of cytological abnormality. In HSIL cases, the staining distribution was as follows : 65% full thickness (figure 3), 35% basal and intermediate. The staining intensity for HSIL cases was strong in 80% (figures 1, 3), moderate in 16%, and weak in 4% accordingly. Regarding LSIL category, the staining distribution was basal in 75% of cases and occasional in the remaining 25%. There was no LSIL case with full thickness of p16 positivity. The staining intensity of LSIL cases was strong in 20% (figures 2, 4, 5), moderate in 13%, and weak in 67%.

From all cervical smears, the HPV L1 capsid protein was expressed in 46% of LSIL and 24% of HSIL. Expression of L1-capsid proteins was significantly reduced for HPV positive HSIL. In HPV positive LSIL, no significant reduction of L1 capsid protein expression could be demonstrated.

Positive reaction was characterized by the strong staining of the whole nucleus, surrounded by a cytoplasm with no background. In most cases, positive reaction for HR-HPV L1 was positive in typical koilocytes or in dyskeratocytes, presenting nuclear characteristics for HSIL (CIN 2 or CIN 3). In LSIL cases, the positivity of the nuclei was presented only in typical koilocytes (figure 6).

All HPV-positive cases (with morphologic evidence of HPV infection) were also p16-positive, but no significant relationship between HPV infection immunopositivity (active infection) and the intensity and distribution of p16 was found.

DISCUSSIONS

L1 capsid protein is expressed in the active phase of HPV infection and is necessary in viral cellular cycle completion. Consequently, viral protein detection, by immunohistochemical reaction is an evidence of active HPV infection in examined tissue (19). L1 viral capsid protein is considered a major target of the cellular immune

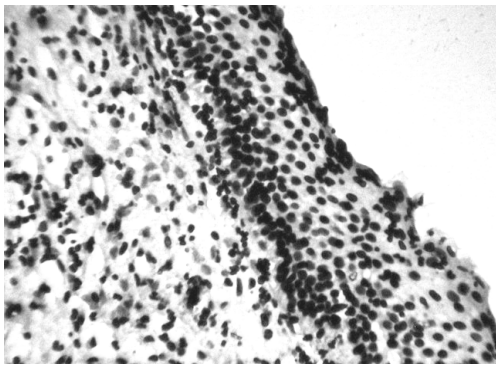

Fig. 1. HSIL (CIN2), strong p16 immunostaining (x10)

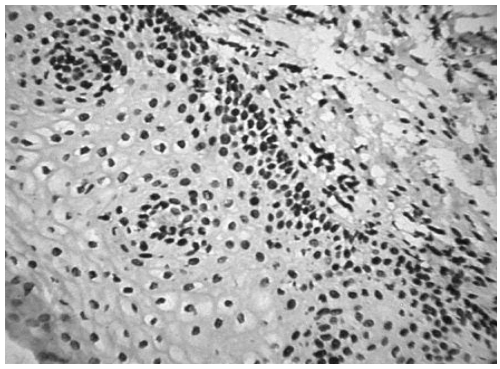

Fig. 2. LSIL, strong p16 immunostaining (x10)

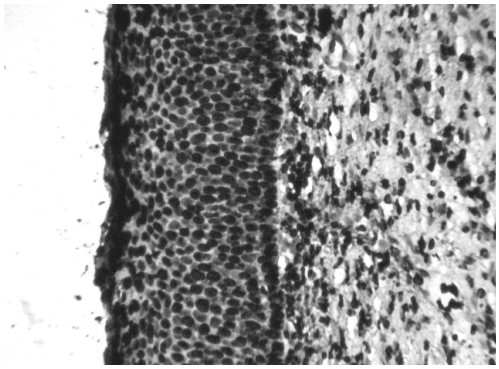

Fig. 3. HSIL (CIN3), strong full thickness p16 immunostaining (x10)

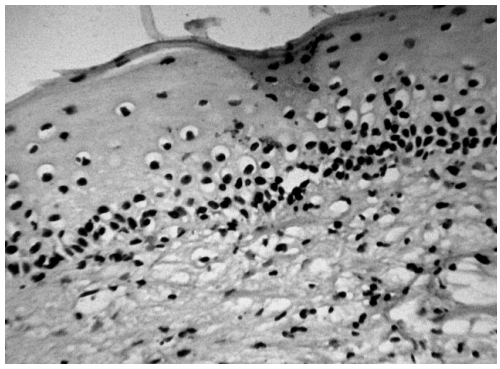

Fig. 4. LSIL, strong p16 immunostaining (x10)

response (20). LSIL and moderate SIL without immunohistochemically detected L1 are correlated, in more than 80% of cases, with dysplasia progression. Griesser et al. certify these aspects, highlighting that minor and moderate lesions without L1 capsid protein expression are significantly more exposed to a progression in comparison to L1 positive cases (21). Most probably, the lack of HPV antigen is determined by a weak protein synthesis, under immunohistochemical test minimum level. As L1 represents the major target of the immune cellular response (22), its deficient translation may result in an inefficient depuration of the infected cells, promoting viral DNA integration in host cellular genome and the transformation of immature epithelial cells. The observation that the decrease of the HPV16 capsid positivity in cervical cancer patients' serum is an indicator of a poor prognosis sustains the importance of a specific humoral response. Immunohistochemical detection of L1 capsid, on conventional Papanicolau smears, may consequently indicate the locally induced defence status on HPV infection and may offer prognosis information, mainly in LSIL lesions.

From all cervical smears, our data revealed that the HPV L1 capsid protein was expressed in 46% of LSIL and 24% of HSIL. Expression of L1-capsid proteins was significantly reduced for HPV positive HSIL. In HPV positive LSIL, no significant reduction of L1 capsid protein expression could be demonstrated. Because of the low rate of

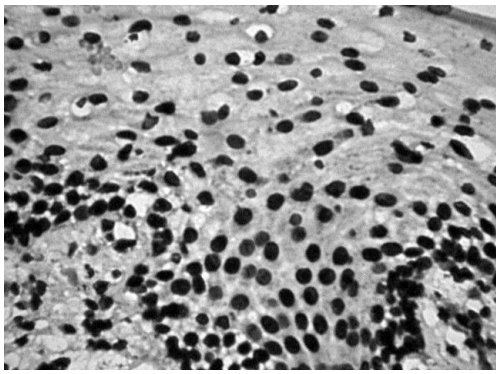

Fig. 5. LSIL, strong p16 immunostaining (x20)

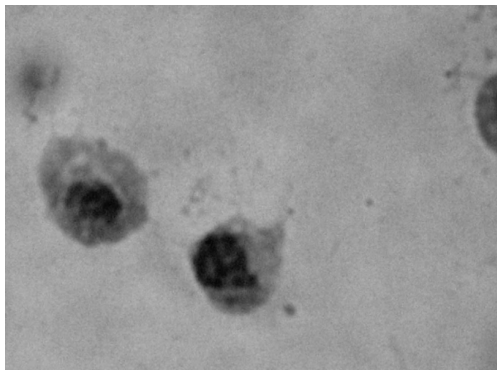

Fig. 6. LSIL, HPV L1 positive (x100)

HR-HPV L1 positivity found in LSIL cases in our study, we can admit that HPV is not helpful in grading cervical SIL, which is in accordance with the literature data (12).

In our study, patients' mean age was 34 years. This fact is consistent with the literature data, where it has been demonstrated that the prevalence of HPV infection varies with age and geographical region, reaching highest rates below 35 years of age (23).

The presence of L1 HPV positively stained nuclei of squamous epithelial cells could be correlated with the clinical course. Expression of L1-capsid proteins was significantly reduced for HPV positive HSIL. In HPV positive LSIL, no significant reduction of L1 capsid protein expression could be demonstrated. Mild and moderate dysplastic cervical lesions without immunohistochemical positive reaction of HPV L1 capsid protein are more likely to progress as compared to positive cases (21). Researches consider that lack of detectable HPV antigen in the Pap smears is due to low protein synthesis in squamous epithelial cells below the limit of the immunocytochemical test. The loss of L1 capsid protein immunoexpression can be the result of the integration of the viral DNA into the human genome. Although most of cervical carcinomas show integration of viral DNA, it is detectable only in a small proportion of LSIL and HSIL (24). As was already reported in the literature (20), perhaps there are additional control mechanisms which lead to the L1-negative immunoexpression in the mentioned cases.

The development of viral capsid antigen L1 depends upon transcriptional factors which only can be expressed during maturation process from basal epithelial cell to superficial epithelial cell (19). In HSIL, the natural structure as well as maturation of the epithelium are disturbed, thus the dysplastic basal squamous cells represent the predominant cell type with reduced L1 capsid protein expression.

P16 is a highly sensitive marker for cervical epithelial dysplasia. Strong and full thickness staining of p16 in the cervix epithelium is highly supportive of HSIL, while weak and basal/rare staining favors LSIL (4).

In our study, from all cervical biopsies, p16 was positive in 68% of LSIL, 84% of CIN2 and 100% of CIN3. The proportion of biopsies with intense immunoexpression of p16 increased with the severity of cytological abnormality. Our results are consistent with the data reported in the literature (25, 26, 27, 28).

As previously reported (14), we also found that all cases morphological HPV positive expressed the p16 protein. No significant relationship between HPV infection immu-

nopositivity (active infection) and the intensity and distribution of p16 was found. This is also supported by Lin et al. (29), who admitted that p16 expression in cervical squamous and glandular epithelium is the marker of dysplasia or malignancy irrespective of the HPV infection status.

Other studies reported the existence of a significant association between cervical squamous intraepithelial lesion grade and p16 intensity and distribution of the immunostaining (30, 31). Regarding the localization of p16 staining, there are authors who report predominant cytoplasmic staining (7) as well as predominant nuclear staining (32, 33), or a combination of both patterns (34).

According to our results, we cannot formulate any definitive statements regarding the applications of p16 in routine practice, excepting its recognized value in certifying the diagnosis of doubtful cases.

CONCLUSIONS

The immunoexpression of L1 HPV has clinical application in the progression assessment of the cervical precancerous lesions without a correlation to the grade of the cervical SIL. The analysis of p16 status, in parallel with protein expression L1 HPV, can be very useful in the assessment of progression risk of cervical squamous intraepithelial lesions.

MORPHOLOGIC PROFILE OF TWO LEUZEA SPECIES HARVESTED FROM WILD FLORA OF EASTERN ROMANIA (Abstract): *Leuzea carthamoides DC and Leuzea salina* are two plant species found in Chinese and Russian traditional medicine for their adaptogen and stress relieving properties. There are still many unknown bioactive compounds that may influence the mechanism of action of these species. Nevertheless, all chemical investigations are directly related to the proper identification of the raw material. **Aim**: In Romania, it is known that two different species of *Leuzea* grow in the wild flora, but there is no data that confirms the difference between the species. Moreover, there are specialists that consider that *L. carthamoides* DC. is a synonym for *Rhaponticum carthamoides* (Willd) Iljin, which rises a series of questions regarding the botanical belonging. Our aim was to observe and assess possible taxonomic differences between the two *Leuzea species*. **Material and methods**: The investigations consisted in the morphologic assessment (microscopy, scanning electronic microscopy) of each important structure found in the roots, stems and leaves of both species on plants harvested from Iasi and Neamt counties in 2017. **Results**: The microscopic observations indicated both similar and different structures that are related to the environmental conditions. Some of the observed features can confirm the species and the growth conditions. **Conclusions**: Although, the results confirmed the taxonomic variability between the investigated samples, further research is still undergoing to assess the chemical and the biological profile based upon the maker compounds important for taxonomy. **Keywords:** *LEUZEA*, ROOTS, LEAVES, MICROSCOPY, VARIABILITY, TAXONOMY.

Leuzea species belong to *Leuzea* genus although, there are researchers that insist that *Leuzea* and *Rhaponticum* genus are synonyms. Moreover, the existent scientific literature presents mainly *Rhaponticum carthamoides* (Willd) Iljin and thus, there is still great need for more data to confirm the taxonomic characteristics of *Leuzea* species. *Leuzea carthamoides* has a long history in traditional Siberian medicine being used to tone the body and combat following a long illness (1-3). It is still presently used as a remedy for male sexual dysfunctions. The bioactive compounds of this species are ecdysteroids, flavonoids and polyphenolic acids (4-9). From this

species, hydroalcoholic extracts from roots administered at a dose of 500 mg / kg body weight in rats increase the locomotor activity, antagonize the narcotic effect of chloralhydrate, increase brain excitability and increase learning memory (4, 7, 10-11). *Leuzea carthamoides* roots decoction corrects depressive status in humans and increases health in patients with somatic gastrointestinal pain. Typically, roots and rhizomes are used to prepare extracts used for the adaptogen and tonic qualities, being incorporated in their entirety or as separate fractions in nutraceutical supplements to promote muscle development, to treat impotence and to eliminate physical and mental fatigue. For this reason, since 1958 *Leuzea* has been in the composition of well-known preparations in mixtures with *Schisandra chinensis, Panax ginseng, Aralia mandshurica* and *Eleutherococcus senticosus*, species with adaptogen properties (9-10).

Regarding *Leuzea salina* there is not much mentioned in scientific literature and according to our observations the plant has a short and thick rhizome with numerous long, thick, black-and-brown roots. Also, the erect stem is thick, cylindrical, simple, finely striated, 60-75 cm tall, while the basal leaves form long rosettes, but the rest of the leaves are petiolate, ovate or elliptic. The flowers of magenta color are similar to *Leuzea carthamoides* (2-3, 11).

The purpose of our research is the comparative investigation of two species of Leuzea, namely a species recognized as a medicinal species, *Leuzea carthamoides* DC, and a species about which there is almost no data in specialized literature: *Leuzea salina*. Our intention was to study the two *Leuzea* species in terms of morphological and histological characteristics in order to identify possible taxonomic similarities and differences.

MATERIAL AND METHODS

The plant material was harvested from the wild flora in the summer of 2017; *Leuzea carthamoides* was collected from Neamt county, whereas *Leuzea salina* raw material was obtained from Iasi County. The sampling of individuals was done for each species within the Biology Faculty, "Al. I. Cuza" University Iasi. The vegetal material was represented by the underground and aerial vegetative organs taken from plants in the antecedent stage. Vegetative organs were fixed and conserved in 70º alcohol. For both samples various types of sections were made using botanical microtome and shock marrow, as follows: upper, middle and inferior transversal axial sections through root, rhizome and stem, also transversal and superficial sections through the lamina (at the median and lateral ribs) were obtained.

Clarification and coloring of the sections

The sections thus obtained were collected and the cellular content was removed by introducing the vegetal material sections into a few drops of sodium hypochlorite, where different time for contact was used depending on the vegetative organ from which they originated (underground organs - 20 minutes, stems - 15 minutes, leaf-10 minutes). Superficial sections of the leaf and leaf stalks have not been mapped. The clarified sections were processed in conformity with double coloring technique (iodine green and red ruthenium), but the superficial sections of the leaves and stems were colored only once with one of the mentioned reagents. As a result of the double coloration: the lignified cell walls are colored in

blue, and the non-lignified in violet; the suberus is colored green, and the parenchyma and the phloem in red and pink.

Thus, the plant material was fixed in glutaraldehyde, dried at the critical point, metallized and then observed and photographed with a photonic microscope (Teskan Electronic Scanning Microscope).

Reagents and equipment

The used apparatus was first Novex Holland Microscope with Sony Cyber-shot DSC-W730 and then Teskan Electronic Scanning Microscope (SEM).

Green iodine is obtained from one gram of iodine green is dissolved in 100 ml of hexane, whereas red ruthenium is obtained by dissolving 0.02 g of ruthenium red in 100 ml of distilled water; add a thymol crystal for preservation.

RESULTS AND DISCUSSION

The results indicated both similarities and differences for the investigated samples. Briefly, at the severed level, *Leuzea carthamoides* root has a typically secondary structure. On the outside of the bark there was a very thin periderm with 1-2 layers of cork cells. The primary bark is parenchymal (relatively thick, 10-12 layers), consisting of slightly elongated tangential cells. The most internal layer is an endodermis with cells having lignified and suberized walls. The central cylinder showed parenchymal cells, many vascular bundles (phloem and xylem solitary or grouped vessels). The secondary fibers have fairly numerous pits and were often arranged in radar strings which intertwine the phloem resulting in incomplete rays. The phloem vessels of variable diameter are composed of cells with moderately thick walls irregularly arranged, in incomplete radar areas as shown in the image below (fig. 1).

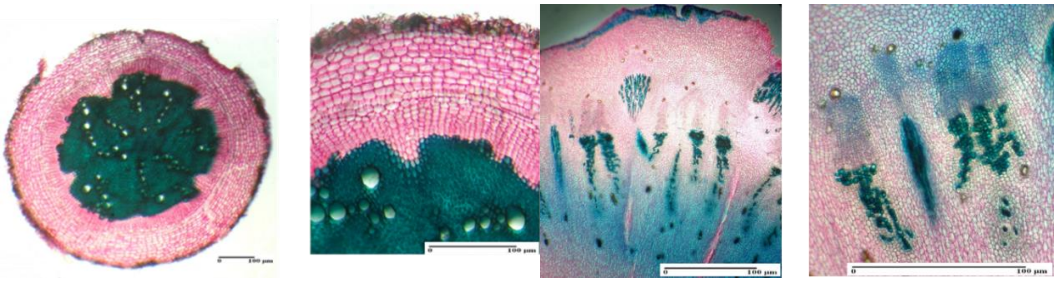

Fig. 1. *Leuzea carthamoides* roots and rhizomes – sectional view with detail

Our findings indicate that at the sectional level Leuzea salina presents mainly a primary structure, as opposed to what we have seen in *L. carthamoides*. The cortical parenchyma is very thick, with small cells, including numerous air cavities. The inner layer is made of small cells elongated tangentially, alternating with those of the pericardium. The central cylinder is relatively thick with parenchymal cells, larger air cavities surrounded by interfascicular cellular parenchyma are observed between the phloem and xylem fascicles. A detailed view is presented in the following image (fig 2).

At the electronic scanning microscope (SEM) we noticed that the cortical cells are heavily elongated and all the thin wall (fig. 3).

The SEM images for *Leuzea salina* roots are shown in the figure 4. The details seem different from the other investigated species.

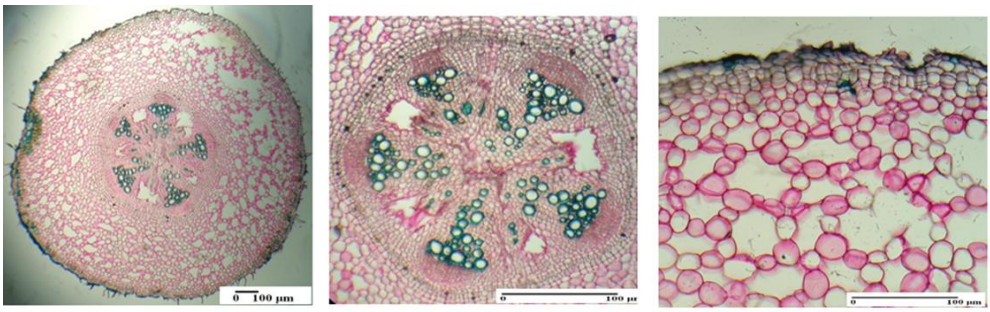

Fig. 2. *Leuzea salina* roots and rhizomes – sectional view with detail

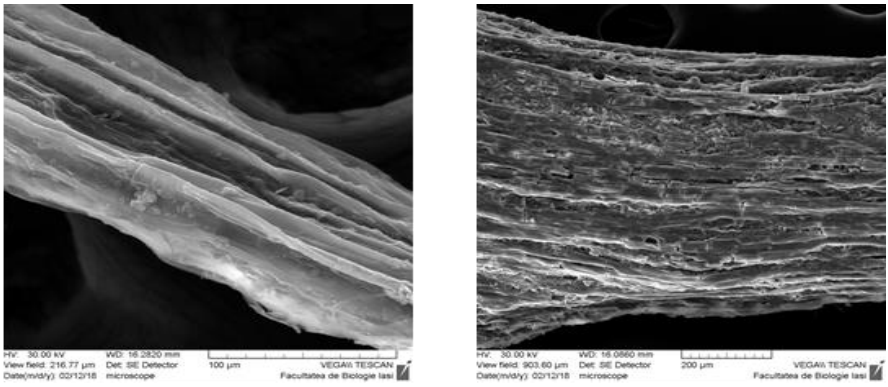

Fig. 3. The root of *Leuzea carthamoides* seen on the SEM:
lateral root to the top (left); cortical cells (right)

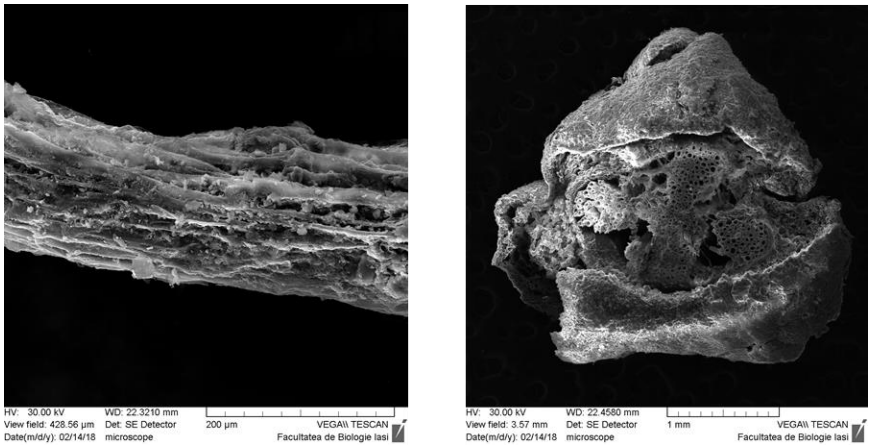

Fig. 4. *Leuzea salina* seen at the scanning electron microscope:
rhizoderma (left); the root seen in cross-section (right)

Considering the rest of the analyzed plant parts, the stem of *Leuzea carthamoides* is extremely short, with early primordial structure, where the conductor bundles did not differentiate, being surrounded by several leaves of different size and age, making several concentric circles. Nevertheless, the characteristics of *Leuzea salina* stem are different, the contour of the cross section is circularly with a thin bark, air cavities and the hypodermis is composed of collenchyma within the ribs section. The epidermis exhibits isodiametric cells at the ribs and slightly elongated tangentially to the valleys. All these elements are clearly visible in the photographs included below (fig 5).

A particular feature that is visible only for *L. salina* in SEM, is the presence of salt glands of particular structure, among the epidermal cells.

Fig. 5. Stem cross-section general view and detail:
A - *Leuzea carthamoides*; B- *Leuzea salina*

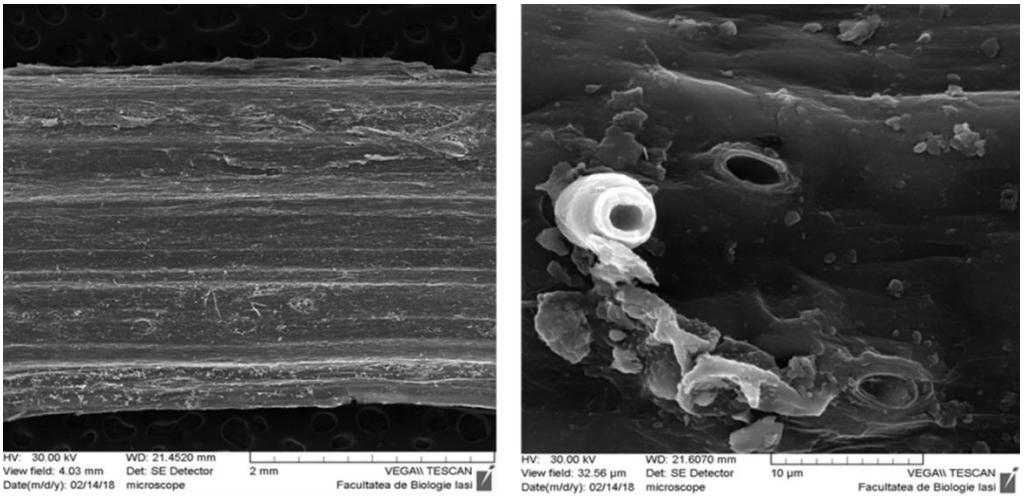

Fig. **6.** Salt glands from the epidermis of the stem in *Leuzea salina* (SEM)

Such elements, which were not observed in *L. carthamoides*, are largely discussed in the old scientific literature as a characteristic for halophytic plants. Nevertheless, there is a lack of proper information in regards to these glands and their actual role for the plants (12-13). This is why we need to further investigate the type of the mineral elements that are secreted.

The mature leaf of *Leuzea carthamoides* has a semicircular cross-sectional shape

with a wide and superficial adaxial groove delimited by two latero-adaxial ridges in which homogeneous parenchyma is observed and a small vascular bundle located in front of a thin cordon of hypodermic collenchyma. The epidermis exhibits isodiametric cells with the external wall slightly thicker than the others and with a thin cuticle. From place to place, stomata are observed. Moreover, the fundamental parenchyma has cells whose size decreases towards the inside of the organ. The hypodermic layer presents a thin layer of collenchyma cells, and in the two latero-adaxial ridges the collenchyma cells have visibly thickened walls (fig. 7).

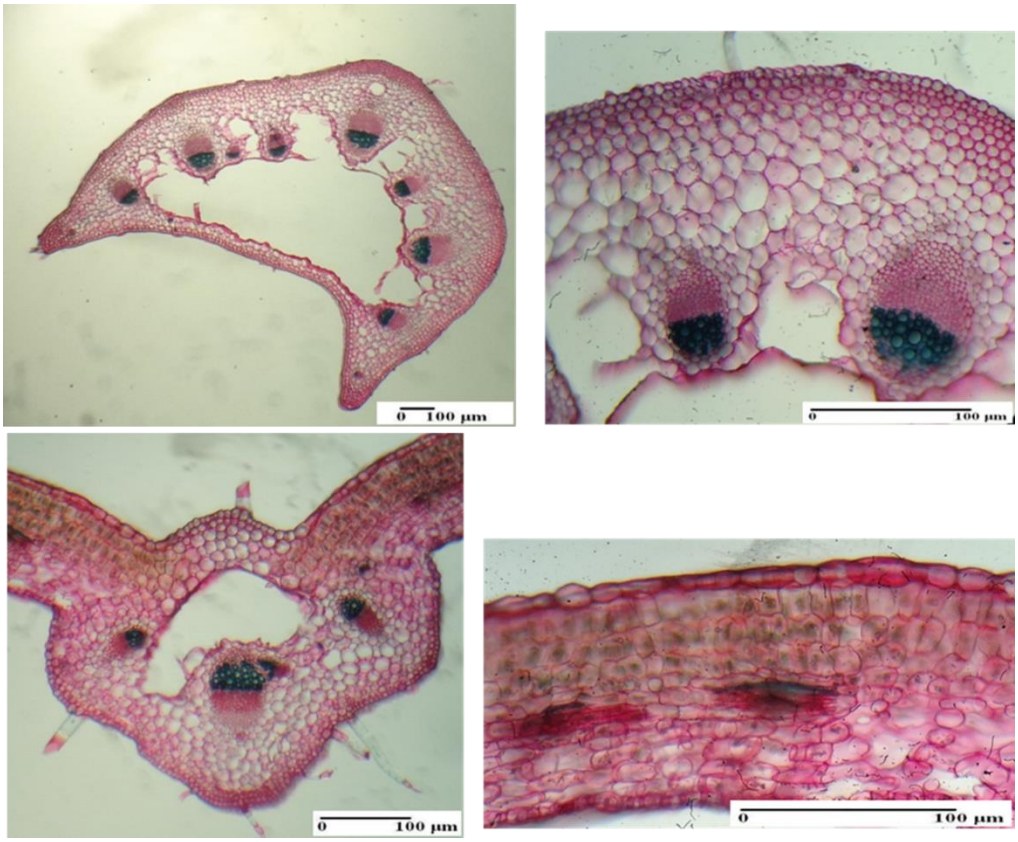

Fig. 7. Transverse section through *Leuzea carthamoides* leaves: petiole (upper images), lamina (lower images)

In the transverse section through the limb of *Leuzea salina*, the medial rib is thick and protruding at the lower face. In the thickness of the median rib, the chloroplast-free parenchyma predominates in which there are usually between 10-12 vascular bunches of different size, arranged on a spring form, all of which have a primary structure. The epidermis presents slightly elongated cells tangentially to the external wall thicker than the others and thinly cutinized. From place to place we see pluricellular, relatively short salt glands, nonexistent in *Leuzea car-*

thamoides. The mesophyll is almost totally palisaded, with relatively short and wide cells, so the limb has a bifacial structure (equiaxial) (fig. 8)

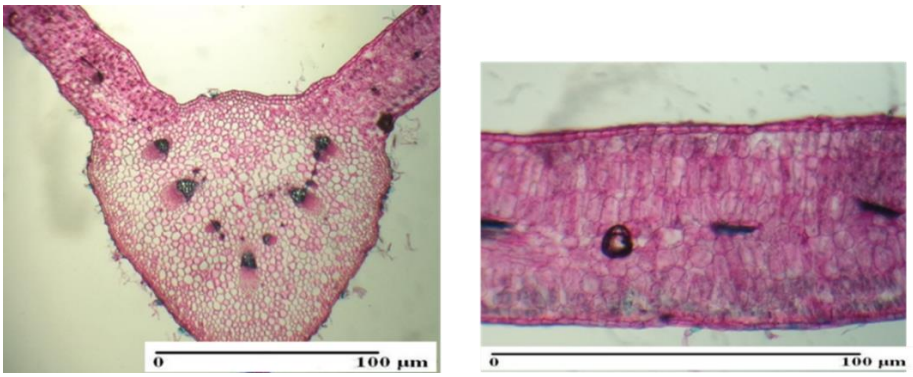

Fig. 8. Cross-section through the leaf of *Leuzea salina*: median rib (left); mesophyll (right)

Irrespective of size, all vascular bundles have pits, tracheid, sieve-tubes elements and intermediary cells. The xylem is formed of separate parenchymal cell vessels with thick and lignified walls. A peripherical cord of collenchyma elements and some mechanical cells with moderately thick and lignified walls were noted along with the larger vascular bundles.

In the scanning electron microscope, the epidermal cells on the lower and upper face of the leaf appear irregular with irregularly curved lateral walls, and among them there are stomata, which are elliptical, and the walls defining the ostiole are very thick (fig. 9).

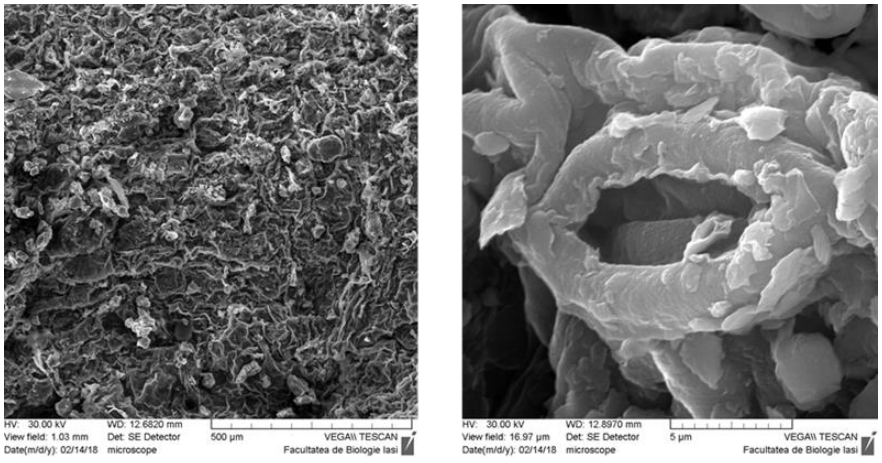

Fig. 9. Epidermis (left) and stomata (right) from *Leuzea salina* in SEM view

CONCLUSIONS

In the present paper we presented the results of the histoanatomical studies conducted for the rhizomes, roots and the aerial part of two *Leuzea* species. Our conclusion is that the cross sections of each ana-

lyzed sections sustain that the species are related and justify the inclusion in the same genus. Nevertheless, the noted differences especially in terms of tissue type and certain elements found only in *Leuzea salina*, suggest that the investigated species are different. Such features important for taxonomic classification at the generic level represent the novelty of our research. However, the chemical composition and the pharmacological action of the extracts that follow closely the similarities and differences between the two species remains to be further investigated. Also, *Leuzea salina*, unknown for its bioactive potential may also become interesting as a supplier of ecdysteroid compounds.

CONFLICT OF INTEREST

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

POSTERIOR FOSA MENINGIOMAS TOPOGRAPHIC AND ANATOMOPATHOLOGIC ASPECTS (Abstract): Meningiomas are the most frequent met intracranial tumors. Many authors tried to order them according to location, origin and histopatologic type. **Material and method**: Our study is focused on posterior fosa meningiomas, initially classified according to their origin based on IRM and surgical findings in order to identify correlations between demographic data, topographic tumor origin and anatomopathologic characteristics for each subgroup. 35 posterior fosa meningioma patients that have been subject to neurosurgery in Iaşi "Prof.Dr. N. Oblu" Hospital Neurosurgery Clinic between January 1st 2005 and December 1st 2009 were assessed. **Results**: In our study group the majority of patients were females, with an average age in their early 60's. Benign meningiomas (Ist degree) represented the unique subtype in tumors located in cerebelum convexity and foramen magnum. Other locations have different chracteristic subtypes (fibrous vs. angiomatous meningioma). **Key words**: MENINGIOMA, HISTOPATHOLOGY, POSTERIOR FOSA

Meningioamele reprezintă una din cele mai frecvente tumori intracraniene. În 1938, Cushing şi Eisenhardt au realizat o clasificare a meningioamelor funcţie de locul de origine, clasificare ce se foloseşte şi în prezent în practica neurochirurgicală (1). După această dată au urmat şi alte clasificări ale meningioamelor intracraniene funcţie de originea lor durală. Aceste clasificări nu oferă informaţii privind malignitatea sau tipul lor histologic, dar neurochirurgul foloseşte aceste date pentru stabilirea abordului chirurgical (2).

Roberti et al. (3) au clasificat meningioamele de fosă posterioară în şase grupe: tipul I: tumori localizate pe convexitatea cerebeloasă şi tentoriul lateral (tentorium, sinusurile transverse sigmoide); tipul II: tumori localizate în unghiul cerebelopontin (aripa pietroasă, conductul auditiv intern); tipul III: tumori localizate la nivelul foramen jugular (unghiul cerebelo-medular, vena jugulară internă); tipul IV: tumori petroclivale (2/3 superioare ale clivusului, sinusul cavernos, cavum Meckel, aripa pietroasă); tipul V: tumori de foramen magnum (1/3 infe-

rioară a clivusului, aria C1-C2); tipul VI: tumori neclasificate (tumori gigante, extinse în mai multe arii).

Bradac et al. (4) au împărţit meningioamele de fosă posterioară în patru grupe: 1. meningioame tentoriale - tumorile localizate pe suprafaţa tentorium cerebelli; 2. meningioame clivale – tumorile cu originea la nivelul treimii superioare a clivusului în direcţia fosei craniene mijlocii sau în direcţia trunchiului cerebral; 3. meningioame de unghi pontocerebelos – tumorile cu originea la nivelul porţiunii medii a osului pietros; 4. meningioamele de foramen magnum – tumorile localizate la nivelul sau în apropierea marginii anterioare a foramenului.

Studiul de faţă analizează meningioamele de fosă posterioară, clasificate iniţial funcţie de locul lor de origine pe baza CT, IRM şi a observaţiei chirurgicale pentru a identifica posibilele corelaţii dintre datele demografice ale pacienţilor cu meningioame de fosă posterioară, locul de origine a acestor tumori şi caracteristicile anatomopatologice ale fiecărui subgrup.

MATERIAL ŞI METODĂ

Au fost luaţi în studiu 35 de pacienţi cu meningioame de fosă posterioară care au fost supuşi unei intervenţii neurochirurgicale pentru ablaţia tumorii în perioada 1 ianuarie 2005 – 1 decembrie 2009 în Clinica de Neurochirurgie a Spitalului Clinic de Urgenţă „Prof.Dr. N. Oblu" Iaşi. Analiza a inclus: vârsta şi sexul pacienţilor, localizarea şi aspectele anatomopatologice ale tumorii rezecate.

În funcţie de relaţiile anatomice cu structurile fosei posterioare, cele 35 de meningioame au fost clasificate în 5 tipuri: 1. tumori de convexitate cerebeloasă (tentorium cerebelli, sinusurile sigmoide transverse); 2. tumori de unghi pontocerebelos; 3. tumori petroclivale (2/3 superioare ale clivusului, foramen jugular); 4. tumori de foramen magnum (1/3 inferioară de clivus, aria C1-C2) şi 5. tumori neclasificate (ataşament dural larg în arii multiple ale fosei posterioare) (tab. I).

Piesele de exereză chirurgicală au fost prelucrate cu tehnica histopatologică clasică (fixare în formaldehidă 10%, includere la parafină şi colorare cu hematoxilină-eozină şi van Gieson). Pentru determinarea gradului de proliferare al meningioamelor de fosă posterioară, secţiunile au fost studiate cu anticorpii Ki-67 folosind tehnica imunohistochemică EnVision.

Pe baza schemei de clasificare a Organizaţiei Mondiale a Sănătăţii, 2007 (5) şi luând în considerare rezultatele obţinute prin investigaţia imunohistochimică, toate cazurile au fost clasificate în trei grupe histopatologice: benigne (I), atipice (II) şi maligne (III) şi s-a notat fiecare subtip histopatologic (tab. II).

REZULTATE

În seria noastră, meningioamele de fosă posterioară au prezentat sex ratio femei/bărbaţi de 3,33:1. Din cele 35 de cazuri, 27 de cazuri (77,14%) au fost femei cu o vîrstă ce a variat între 36 şi 73 ani (vârsta medie fiind de 52,8 ani). Restul de 8 cazuri (22,86%) au fost pacienţi de sex masculin cu o vârstă variind între 35 şi 57 ani (vârsta medie fiind de 47,1 ani).

Vârsta medie pentru toate meningioa-

Gradul II	1				2			1			**4 (11,42%)**
Gradul III	1	1									**2 (5,71%)**

TABELUL III

Meningioamele de fosă posterioară: clasificare funcţie de locul de origine şi subtipurile histologice

Subtipul histologic	Ne-clasificate	Convexitate cerebeloasă	Unghi ponto-cerebelos	Petro-clival	Foramen magnum	Nr. cazuri (%)
Fibros	1	5	5			11 (37,79%)
Psamomatos	2		2	1	2	7 (24,13%)
Meningotelial			3	1		4 (13,79%)
Secretor			2	1	1	4 (13,79%)
Angiomatos			3			3 (10,34%)
Atipic	1		2	1		4 (11,42%)
Anaplastic	2					2 (5,71%)
Total	6 (17,14%)	5 (14,28%)	17 (48,57%)	4 (11,42%)	3 (8,57%)	35 (100%)

mele de fosă posterioară a fost de 51,6 ani. Meningioamele gigante ce au afectat o mare parte din fosa posterioară s-au întâlnit la pacienţii de sex masculin mai tineri decât vârsta medie (43,33 ani). Vârsta pacienţilor de sex feminin a fost mai mare decât vârsta medie a grupului în cazul meningioamelor de convexitate cerebeloasă (64,25%).

Meningioamele de grad I (fig. 1 şi 2) au fost întâlnite în majoritatea cazurilor (82,85%), în timp ce tumorile de grad II (fig. 3 şi 4) au fost diagnosticate în 11,42% din cazuri, iar tumorile anaplazice doar în 5,71% din toate cazurile analizate. Meningioamele atipice

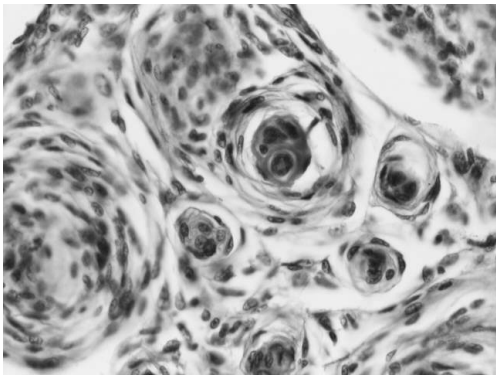

Fig. 1. Meningiom meningotelial grad I (H&E, x200)

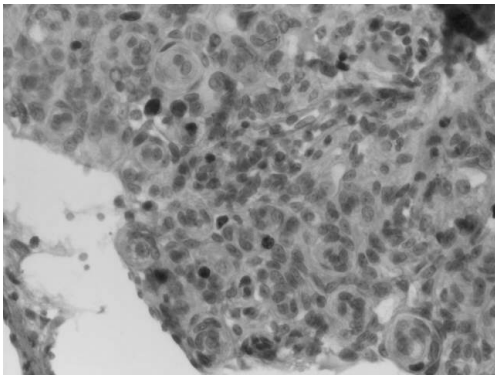

Fig. 2. Meningiom meningotelial grad I – 2% din celulele tumorale sunt pozitive pentru anticorpul Ki-67 (reacţia de imunocolorare cu anticorpul Ki-67, x200)

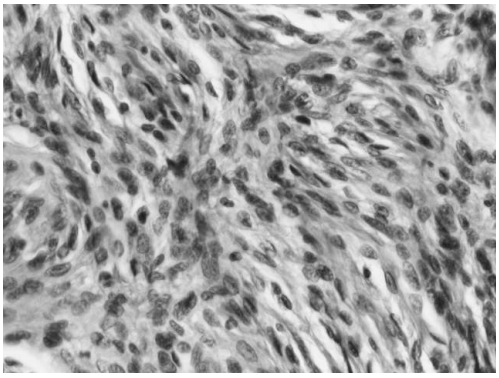

Fig. 3. Meningiom atipic grad II (H&E, x200)

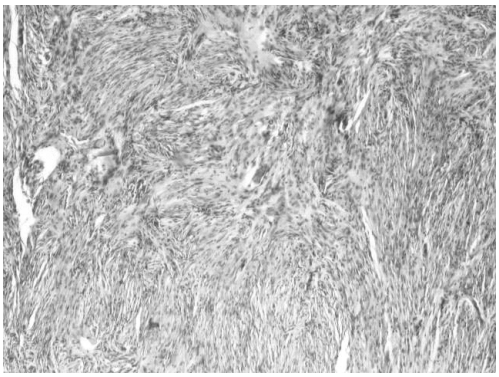

Fig. 5. Meningiom fibros (H&E, x100)

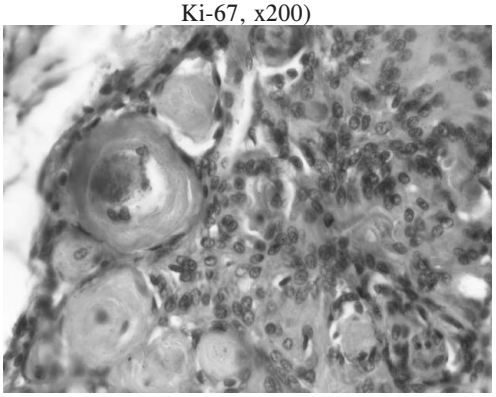

Fig. 6. Meningiom psamomatos (H&E, x200)

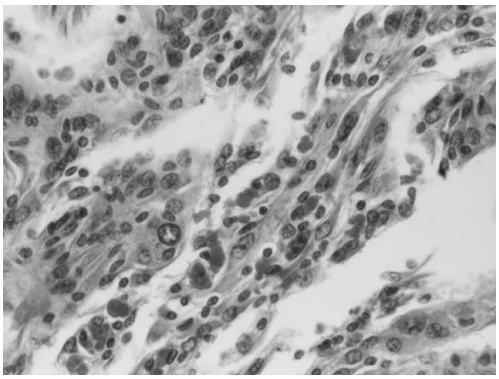

Fig. 7. Meningiom secretor (H&E, x200)

(grad II) au fost diagnosticate în unghiul ponto-cerebelos şi în aria petroclivală. Meningioamele maligne (grad III) nu au putut fi localizate într-un compartiment specific al fosei posterioare deoarece au fost operate în momentul în care au atins dimensiuni foarte mari.

29 de pacienţi au prezentat ataşament dural distinct la unul din cele patru compartimente menţionate ale fosei posterioare (convexitatea cerebeloasă – 14,28%, unghiul ponto-cerebelos – 48,57%, petro-clival – 11,42% şi foramen magnum – 8,57%), iar 6 pacienţi (17,14%) au avut ataşament dural larg în multiple arii ale fosei posterioare.

Cel mai frecvent, la nivelul fosei posterioare s-au dezvoltat subtipurile histologice benigne fibros (37,79%) (fig. 5) şi psamomatos (24,13%) (fig. 6). Puţine cazuri au fost de tip angiomatos (10,34%). Meningioamele atipice şi anaplazice au reprezentat 17,13% din toate meningioamele de fosă posterioară. Luând în considerare subtipul

histologic şi locaţia tumorilor, am constatat că la nivelul convexităţii cerebeloase s-au dezvoltat numai meningioame fibroase. Unica locaţie a subtipului angiomatos a fost unghiul ponto-cerebelos. Subtipul psamomatos a predominat în locaţia foramen magnum. Unghiul ponto-cerebelos a prezentat toate subtipurile histologice de meningioame, inclusiv subtipul secretor (fig. 7).

DISCUŢII

Meningioamele de fosă posterioară prezintă o provocare formidabilă pentru neurochirurg şi multe tumori, mai ales cele localizate în regiunea petro-clivală au fost considerate „inoperabile" până în anii 1970. Însă, o dată cu dezvoltarea noilor tehnologii (microscop operator, computertomografie, rezonanţa magnetică nucleară) şi cu dezvoltarea unor noi abordări neurochirurgicale asupra bazei craniului, a devenit posibilă intervenţia neurochirurgicală „în siguranţă" asupra majorităţii meningioamelor de fosă posterioară.

Locaţia tumorii este cel mai important aspect ce poate influenţa terapia deoarece defineşte modalitatea intervenţiei chirurgicale. Aceste tumori apar mai frecvent la nivelul tentoriumului, emisferelor cerebeloase şi unghiului ponto-cerebelos, dar ele pot fi găsite de asemenea de-a lungul clivusului şi pe marginea anterioară a foramen magnum (6).

Frecvenţa meningioamelor funcţie de variatele locaţii intracraniene a variat de la studiu la studiu. Unele din ele au arătat că meningioamele de fosă posterioară reprezintă 6-15% din toate meningioamele intracraniene, meningioamele dezvoltate la nivelul convexităţii cerebeloase se întâlnesc în aproximativ 5% din cazuri, meningioamele de unghi ponto-cerebelos apar în 2-4% din cazuri, iar la nivelul clivusului apar mai puţin de 1% din toate meningioamele intracraniene (7).

Meningioamele unghiului ponto-cerebelos reprezintă cele mai frecvente meningioame de fosă posterioară. Meningioamele de foramen magnum, pe de altă parte, sunt foarte rare. Meningioamele de clivus sunt, de asemenea, mai puţin frecvente (8). Cohen-Gadol şi Al-Mefty (9) au raportat procentaje asemănătoare: 50% din meningioamele de fosă posterioară sunt localizate în unghiul ponto--cerebelos, 40% apar în jurul tentoriumului sau al convexităţii cerebeloase, 9% sunt la nivelul clivusului, iar 6% apar în vecinătatea foramen magnum.

Roberti et al. au găsit alte procente privitoare la frecvenţa meningioamelor de fosă posterioară raportat la localizare. În studiul lor, 68,32% din tumori erau meningioame petroclivale, 13,04% erau meningioame de forame magnum, 8,69% erau meningioame de convexitate cerebeloasă, 5,59% erau meningioame de unghi ponto-cerebelos, iar 4,34% erau meningioame de foramen jugular (3).

În studiul nostru, cea mai frecventă localizare a meningioamelor de fosă posterioară a fost unghiul ponto-cerebelos (48,57%). Numai 8,57% din meningioamele de fosă posterioară s-au dezvoltat la nivelul foramen magnum.

Meningioamele intracraniene au afectat predominant pacienţii aflaţi în decadele a 5-a – a 7-a de viaţă. În literatura de specialitate, sunt prezentate variate valori pentru sex ratio femei/bărbaţi (de la 1,4 : 1 la 2,7 : 1) (3,10), dar meningioamele de fosă posterioară sunt în toate sursele citate mai frecvente la femei. García-Navarrete şi Sola au prezentat 26 de pacienţi cu meningioame de fosă posterioară în cadrul seriei existând sex ratio femei : bărbaţi de 12 : 2 (11). Roberti et al. au raportat 161 de cazuri de meningioame de fosă posterioară şi a găsit un raport femei : bărbaţi de 3,9 : 1 (3), valori aproape similare cu raportul găsit în studiul nostru (3,3 : 1).

Vasta majoritate (92%) a meningioamelor intracraniene au o histologie benignă, în timp ce 8% arată aspecte atipice sau maligne. În ceea ce priveşte meningioamele benigne, cel mai frecvent subtip histologic este de obicei cel meningotelial (63%), urmat de cel tranziţional (19%), fibros (13%) şi psamomatos (2%). Mai puţin de 10% din

meningioame sunt maligne (12).

În studiul de faţă, cele mai frecvente subtipuri histologice benigne dintre meningioamele de fosă posterioară au fost subtipul fibros (37,79%) şi cel psamomatos (24,13%). Meningioamele atipice şi cele maligne au reprezentat 17,13% din toate meningioamele de fosă posterioară luate în studiu, dar seria noastră cuprinde relativ puţine cazuri pentru a avea o concluzie pertinentă.

Meningioamele petroclivale reprezintă aproximativ 3-10% din toate meningioamele de fosă posterioară (13,14,15). Ele prezintă o uşoară predominanţă feminină, fiind înregistrate rapoarte variabile femei : bărbaţi (de la 1,4 : 1 până la 2,8 : 1). Vârsta medie a pacienţilor la prezentare se situează în decada a 5-a de viaţă.

În studiul nostru, meningioamele petroclivale au prezentat o incidenţă mai mare ca în alte studii (11,42% din toate meningioamele de fosă posterioară). Vârsta medie la prezentare pentru pacienţii-femei a fost mai mare (55 ani) decât cea raportată în alte studii, iar pentru pacienţii –bărbaţi a fost de 50 de ani. Meningioamele petroclivale au inclus diferite subtipuri histologice (psamomatos, meningotelial şi secretor) şi chiar un caz anaplastic la un pacient bărbat.

Dintre meningioamele de fosă posterioară, cele localizate la nivelul foramen magnum merită o atenţie deosebită deoarece ele prezintă cel mai rău prognostic atunci când ne referim la rezultatele chirurgicale şi la morbiditatea postoperatorie.

Aceste tumori sunt rare, reprezentând doar 0,3% până la 3,2% din toate meningioamele şi între 4,2% şi 20% din toate meningioamele de fosă posterioară (9,13, 15). Datorită rarităţii cazurilor prezentate, există puţine informaţii privitoare la histologia acestor tumori. Tsao et al. au prezentat histopatologia unui meningiom de foramen magnum arătând că era subtipul meningotelial (16), iar Avninder et al. au prezentat un caz de meningiom bogat în limfoplasmocite în această localizare (17).

În studiul de faţă, meningioamele de foramen magnum au afectat doar femeile aflate în decada a 4-a de viaţă până în decada a 6-a de viaţă (vârsta medie fiind de 52,66 ani). Toate meningioamele de foramen magnum au fost benigne (gradul I), iar subtipul psamomatos a fost cel mai frecvent întâlnit.

Meningioamele de convexitate cerebeloasă reprezintă 6-18% din toate meningioamele de fosă posterioară (9). În studiul de faţă, 14,26% din cele 35 de cazuri de meningioame de fosă posterioară s-au localizat la nivelul convexităţii cerebeloase. Raportul femei : bărbaţi a fost de 4 : 1. Vârsta medie a pacienţilor-femei cu meningioame de convexitate cerebeloasă a fost mai mare (64,25 ani) decât vârsta medie a întregii serii. În această localizare, toate tumorile identificate au prezentat numai histologie benignă (subtipul fibros, 100%).

Deşi mai puţin de 20% din toate meningioamele intracraniene apar în fosa posterioară, aproape jumătate din ele sunt localizate în unghiul ponto-cerebelos. În studiul nostru, meningioamele de unghi ponto-cerebelos reprezintă 48.57% din toate cele 35 de cazuri ale seriri. Am întâlnit o evidentă predominenţă a pacienţilor-femei (raportul femei/bărbaţi = 5 : 1). Vârsta medie, indiferent de sexul pacienţilor, a fost relativ apropiată de vîrsta medie a seriei. 11,74% din meningioamele de unghi pontocerebelos au avut gradul II de malignitate iar restul de 88,23% au evidenţiat o histologie benignă. În această locaţie s-au întâlnit variate subtipuri histologice (fibros, meningotelial, secretor). Numai în această locaţie s-a identificat subtipul angiomatos.

CONCLUZII

În seria noastră, meningioamele de fosă posterioară s-au dovedit a avea un spectru variat în ceea ce priveşte datele demografice şi histologice atunci când le comparăm funcţie de locul de origine a tumorii. Am

identificat o asociere semnificativă între vârstă şi sexul pacienţilor, histologia şi locul de origine a acestor tumori.

S-a constatat o predominenţă a pacienţilor-femei cu o vârstă medie situată în decada a 6-a de viaţă. Meningioamele benigne (grad I) au reprezentat categoria unică în cazul localizării la nivelul convexităţii cerebeloase şi la nivelul foramen magnum, existând subtipuri diferite (de ex. cel fibros versus cel angiomatos) ce au caracterizat fiecare locaţie.

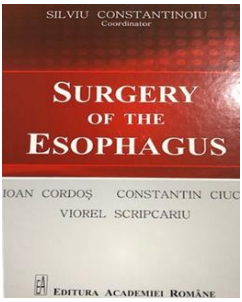
BOOK REVIEW



SURGERY OF THE ESOPHAGUS

Silviu Constantinoiu, Ioan Cordoș, Constantin Ciuce, Viorel Scripcariu

Editura Academiei Române 2019

This year, the Romanian Academy Publishing House published a treatise on esophageal pathology and surgery, under the coordination of Professor S. Constantinoiu and the editorial staff comprised of I. Cordoş, C. Ciuce, V. Scripcariu, a remarkable editorial event for the Romanian medical literature. The conception, organization and publication of such a treatise covering all aspects of the esophageal surgical pathology demonstrates the strength of the contemporary Romanian surgical community, which the publisher managed to mobilize, and the continuation of an internationally recognized tradition through the graces of Professor Dan Gavriliu, who published about esophageal surgery in 1957.

This work reflects the achievements of Romanian surgery and a synthesis of the progresses that esophageal surgery has seen over recent years.

Throughout its 839 pages, the treatise, well-structured in 17 chapters, brings together a wide range of national and international collaborations (47 authors) and provides specialists with the latest data on esophageal surgical pathology.

The first chapter, signed by Professor S. Constantinoiu, also passionate about the history of medicine, describes in detail the history of esophageal surgery. Along with the general history of esophageal surgery, the chapter presents the first efforts of the Romanian school of surgery regarding the esophagus - Amza Jianu, Iancu Jianu, Dan Gavriliu, as well as other Romanian surgeons from the past or present and their surgical centers in Bucharest, Iasi, Cluj, Timisoara, Oradea, Constanta, Craiova and Sibiu.

The following 4 chapters address the surgical anatomy and the physiology of the esophagus (D. Predescu, S. Constantinoiu), superior digestive endoscopy in esophageal pathology (Daniela Dinu, P. Hoară, Irina Predescu, D. Predescu), esophageal imaging (D. Predescu, S. Constantinoiu) and functional investigations (P. Hoară, Rodica Bârlă).

A textbook on esophageal surgery would not have been complete without a chapter on anesthesia and intensive care (Chapter 6). The first sub-chapter, the one on anesthetic technics, is written by dr. Radu Stoica and dr. Genoveva Cadar. The following well-documented sub-chapters deal with nutrition and intensive care in patients with esophageal pathology. These sub-chapters are written by prof. dr. Ioana Grigoras, dr. Irina Ristescu and dr. Emilia Patrascanu, who co-authored the chapter on intensive care (from the Regional Oncology Institute of Iasi).

Chapter 7 extensively describes esophageal atresia and tracheoesophageal fistulae (R. Drașovean, C. Ciuce).

A complex chapter (Chapter 8), which captures the reader through the novelty of

the information provided, refers to gastro-esophageal reflux pathology, which is so common nowadays. Hiatal hernias (S. Constantinoiu, Cristina Gîndea), signs of reflux disease (GERD) and its complications (A. Constantin, Fl. Achim), functional and imaging investigations in GERD (P. Hoară, Daniela Dinu, A. Caragui) are presented in great detail. Barrett esophagus (Rodica Bîrlă) occupies a central spot, being approached from a multidisciplinary point of view: diagnosis, pathological anatomy, complications, indications for medical and surgical treatment, adeno-carcinoma developed on Barrett esophagus. Next, the chapter also covers medical treatment in GERD, indications of surgical treatment in hiatal hernia and GERD, classical and laparoscopic surgical techniques in hiatal hernia and GERD (Nissen, Dor and Toupet, Belsey - Mark IV operation, surgery for GERD complications, esophageal stenting etc.) (S. Constantinoiu *et al.*), unconventional minimally invasive therapy for GERD (A.E. Nicolau, A. Lobonţiu), reflux disease associated with obesity (C. Copăescu), hiatal ant reflux surgery failures, Roux-en-Y procedure in GERD (I.N. Mateş).

Esophageal motility disorders and their morphological consequences on the surgical approach follow: the Zenker and Killian –Jamieson diverticula, the medial thoracic diverticulum and the epiphrenic diverticulum, each described in a separate chapter (Chapter 9). Due to their extensive experience in this area of esophageal pathology, the team from the Clinical Hospital "Sf. Maria" explains in the chapter on achalasia cardia its multiple etiopathogenetic hypotheses, clinical appearance, diagnostic (esophageal manometry, barium exam and endoscopy). The treatment is multimodal, but mainly surgical – LES myotomy. The latest trend in Heller myotomy is also presented – sectioning LES muscles endoscopically. Other therapeutic methods in achalasia cardia are described as well: medication (calcium channels blockers, nitrates), local injections of botulinic toxin, pneumatic dilation, together with their limitations. Dr. Matias Losano Brotons from South America has described with accurate information the Chagas disease

Chapter 10 is dedicated to post-caustic esophagitis: etiology and diagnosis (D. Predescu), treatment (V. Binţinţan, C. Ciuce), esophageal reconstruction techniques using right ileo-colon and transverse colon, left colon (D. Predescu, S. Constantinoiu).

The following two chapters address esophageal foreign bodies and trauma to the esophagus (perforations and contusions, Boerhaave syndrome).

Chapter 13 treats benign esophageal tumors (I. Cordoş, C. Bolca). All types of esophageal benign tumors are described: the parietal structure they originated from, their ways of development (intraluminal, interparietal, extra parietal), the possibility of compression on neighboring organs (trachea, heart, aorta). The possible surgical approaches are also mentioned: endoscopic, classical or minimally invasive. The main aims are removing the benign tumor and saving the host organ.

An important chapter, extensively developed, is Chapter 14, dedicated to esophageal cancer, with 8 subchapters: epidemiology and etiopathogenesis (S. Constantinoiu, I.N. Mateş), clinical aspects (R. Scurtu, G. Dindelegan, C. Ciuce), imaging and staging of esophageal cancer (V. Scripcariu, B. Filip), pathological anatomy (Cristina Iosif, Simona Enache), radiochemistry in esophageal cancer (Rodica Anghel), stenting in locally advanced stages (G. Dimofte), and esophageal bypass (I.N. Mateş, S. Constantinoiu).

Chapter 15 extensively presents the sur-

gical treatment of esophageal cancer: approaches of the cervical and cervical-mediastinal esophagus (S. Constantinoiu, Fl. Achim), reconstruction of the pharynx and cervical esophagus through free jejunum transfer (C. Ciuce), esophagus approaches via the thorax (I. Cordoș, C. Bolca), Sloan Orringer trans hiatal esophagectomy (S. Constantinoiu), McKeown triple approach esophagectomy, radical esophagectomy (I. Cordoș), three-field lymphadenectomy in esophageal cancer (V. Scripcariu, B. Filip), minimally invasive esophagectomy, robotic esophagectomy (S. Constantinoiu, Fl. Achim), reconstruction of the esophagus with colonic interposition (R. Scurtu, C. Ciuce), or with the stomach (I. Cordoș) in esophageal cancer, postoperative period (Luminița Cociu), complications of esophageal resection (C. Ciuce), quality of life and prognosis in esophageal cancer patients (V. Scripcariu, B. Filip).

Chapter 16 provides new data on esogastric junction adenocarcinoma: the relation between GERD-Barrett's esophagus-EGJ ADK, the classification of EGJ adenocarcinomas, the clinical presentation, imagistic investigations, staging, pathological anatomy, endoscopic treatment (endoscopic mucosal resection, endoscopic submucosal dissection (ESD) and endoscopic ablation techniques – radiofrequency, PDT therapy, APC, laser therapy, cryotherapy), surgical treatment (the Ivor Lewis procedure, total gastrectomy with trans hiatal Hill esophagectomy and Roux- en-Y reconstruction, the triple approach of EGJ adenocarcinomas), radio chemotherapy, palliative treatment, survival and prognosis.

The last chapter presents an exhaustive analysis of GIST in general and of the esophageal ones in particular (M. Gheorghe, S. Constantinoiu) as well as the study of other rare esophageal tumors (I.N. Mates, M. Gheorghe). Both sub-chapters present an update in the study of these tumors.

The treatise, based on a rich Romanian experience and on the study of an exhaustive recent bibliography is easy to go through due to the concise, orderly and clear style and to modern editing. The very rich, good quality, color iconography renders the work an academic feel.

The excellent graphic state honors the Romanian Academy Publishing House, which has published this volume. The treatise is addressed to resident doctors, specialists and consultants of general surgery, thoracic surgery, ENT, oromaxilofacial surgery, but also to residents and specialists in related fields (gastroenterology, anesthesiology and intensive care), as well as to all those who want to add to their knowledge of surgery.

As the renowned thoracic surgery Professor T. Horvat said in his foreword, *"this treatise is the missing granite stone from the edifice of Romanian surgical literature, it is the treatise of the current generation of surgeons, which will only be written once again after a generation will have passed"*.

The publishing of this masterly treatise, the most complete and up-to-date in Romanian literature, represents a special editorial event, and the editor, known for his high professionalism, for the passion and perseverance he puts into everything he accomplishes, is part of the rare category of people who make up the drive and the engine of going forward.

CLINICAL APPLICATIONS OF MOLECULAR BIOMARKERS IN PROSTATE CANCER DETECTION (Abstract): Prostate cancer is a heterogeneous disease with regard to molecular alterations and clinical course. Early diagnosis of prostate cancer can increase the curative success rate for this disease. Because of the recent developments in the field of molecular biology, an increased interest occurred for molecular biomarkers, as tools for early prostate cancer detection, monitoring disease progression, predicting disease recurrence and therapeutic treatment efficacy. Many molecular biomarkers have been discovered in human serum, urine, seminal fluid and histological specimens. **Key words**: PROSTATE CANCER (PCA), BIOMARKERS, BENIGN PROSTATIC HYPERPLASIA (BPH)

THE ACCURACY OF AI-ASSISTED IMAGING DIAGNOSIS *VERSUS* CONVENTIONAL EVALUATION OF DENTAL PROFESSIONALS (Abstract): The accurate detection of dental caries is crucial for effective treatment planning and prevention of disease progression. Artificial intelligence (AI) has emerged as a valuable tool in odonto-periodontal imaging, offering potential improvements in diagnostic accuracy compared to traditional methods employed by dental professionals. This study **aimed** to compare the accuracy of AI-assisted odonto-periodontal imaging in detecting dental caries with diagnoses established by general dentists, specialists, and senior specialists. **Materials and methods:** A comparative analytical study was conducted on a sample of 60 dentists categorized into three professional groups-general dentists, specialists, and senior specialists-alongside AI diagnostics using the Planmeca Romexis platform. **Results:** High-quality panoramic radiographs (OPG) representing various carious lesions were analyzed independently by all participants. Statistical analysis was performed using *SPSS version 26.0,* employing chi-square and ANOVA tests to assess differences among groups. Senior specialists and AI reported the highest number of detected lesions, with AI demonstrating a lower standard deviation, indicating greater consistency. The ANOVA test confirmed significant differences in caries detection across groups ($F=18.849$, $p<.001$), highlighting the superior diagnostic performance of AI. **Conclusions:** This study demonstrates the significant advantages of AI-assisted diagnostic tools in dental-periodontal imaging, particularly in the detection of carious lesions. **Keywords**: AI, DENTAL CAVITIES, ORAL DIAGNOSIS, DENTAL IMAGING.

INTRODUCTION

The capacity of human readers to evaluate a wide range of qualitative aspects is restricted, and their performance varies, when it comes to interpreting medical images. On the other hand, AI is able to reliably and consistently assess a wide variety of quantitative characteristics. Diagnostics,

prognoses, treatment efficacy, and risk assessment are all areas that can benefit from these imaging biomarkers (1, 2).

The use of AI has revolutionized the dental industry and is now an integral part of patient care. Improved diagnostic imaging, treatment planning, patient management, and workflow optimization are just a few ways it has revolutionized dentistry. Image interpretation, charting automation, and treatment result prediction are all enhanced by it (1). Radiographic and CT scan analysis is made more accurate, allowing for more precise diagnosis of diseases including cavities and bone resorption, thanks to its advanced algorithms. Artificial intelligence (AI) uses predictive analytics to develop individualized treatment plans and optimizes the production of orthodontic devices like aligners. Improving patient outcomes is another benefit of AI's real-time clinical decision assistance and thorough risk evaluations (1-3).

It is now generally acknowledged that radiography may greatly benefit from the integration of AI in order to decrease human error, boost efficiency, and accomplish goals with little to no human intervention (3). Conventional imaging modalities, including X-rays, may not pick up on symptoms of illness that aren't immediately obvious (4). By evaluating radiographs and imaging modalities alone or in combination, AI systems may be able to routinely detect these tiny changes, seemingly with amazing precision (5), enabling prompt intervention (6).

Orthopantomogram (OPG), also known as panoramic radiography, is an essential tool in dentistry and orthodontics, providing a detailed image of the dental and bony structures of the oral cavity. By interpreting an OPG, a specialist can identify a range of dental and bone conditions and abnormalities (7).

Recording the patient's oral health and identifying and diagnosing problematic symptoms, such as cavities, are common recurrent activities in the dental field. Personalized suggestions for preventative and surgical care are the ultimate outcome of this evaluation (8). Visual examination is the gold standard in clinical practice since it is simple to do and yields satisfactory results following dental washing and drying. Despite the fact that educated dentists often have strong intra- and inter-examiner repeatability, inconsistent diagnoses are nonetheless seen frequently in clinical practice, even though diagnostic studies have proved this (3, 9, 10, 11). So, it may be a good idea to use AI approaches for independent verification (12-14).

This study proposes to comparatively evaluate the accuracy of AI-assisted odonto-periodontal imaging diagnosis versus the one established by dentists, specialists and senior specialists.

MATERIALS AND METHODS

The comparative analytical study aimed at assessing the accuracy of AI-assisted dental and periodontal imaging diagnosis versus that established by general dentists, specialists and senior specialists was conducted on a group of 60 dentists selected based on their level of professional training.

Study group:

- **Group 1:** 20 general dentists.
- **Group 2:** 20 specialists
- **Group 3:** 20 senior specialists
- **Group 4:** The artificial intelligence (AI) system used for diagnosis (Planmeca Romexis).

To improve diagnosis accuracy and simplify operations in dental clinics, Planmeca Romexis® incorporates several tools and features into its complete software platform. Using cutting-edge imaging technology and AI, it can identify periodontal diseases and cavities, which are two

of its most remarkable features.

When used with Planmeca Emerald® intraoral scanners, the software is compatible with the scanning tip known as Planmeca Cariosity®. In order to identify dental cavities, this set uses radiation-free transillumination technology. Clinicians can see into tooth structure with near-infrared light, which helps them detect early-stage fractures, approximal, occlusal, and secondary cavities. For additional analysis and patient communication, the recorded photos can be saved in the Romexis database.

Dental practitioners benefit from early diagnosis and treatment planning with the help of Planmeca Romexis® software's superior imaging capabilities, which enable the identification of numerous coronal lesions. The method is able to identify a variety of coronal lesions, including:

- calculus deposits
- signs of various dental pathologies and other treatable conditions found in dental radiographs - including hard-to-detect issues such as early-stage cavities or initial signs of periapical radiolucency
- the percentage of carious involvement in the enamel and dentin

The software can identify potential cavities and assist in determining the best treatment plan, such as a filling, an inlay, an onlay, a crown, endodontic treatment, or an extraction. Findings are highlighted with colors and text, providing an easily understandable, independent opinion that helps build patient trust. This enables timely interventions and offers long-term health benefits by improving patient retention.

Selection of cases. Different dento-periodontal diseases (such as periodontitis, interproximal cavities, alveolar bone loss, and periapical lesions) were depicted in six high-quality radiographic pictures (OPG). To make sure the reference diagnosis was legitimate, a senior specialist and an expert in dental imaging had already verified the instances in question.

Participant Intervention. Without seeing the patient's medical history, each participant independently assessed the collection of photos and made a diagnosis based on their findings. A deep learning system trained on comparable data was used to construct the AI diagnostic.

Assessing Performance. All of the dental teams' and the AI's diagnoses were compared to the "gold standard" reference diagnostic.

Statistical analysis. After data collection was complete, *SPSS version 26.0* (IBM, USA) was used for statistical analysis. Frequencies and mean values were used to display the results. It was determined that there were statistically significant variations in the dental-periodontal assessment between the groups using procedures like the chi-square test and ANOVA analysis.

Multiple comparisons on the same data set were corrected statistically using the Bonferroni test because of the small sample size. This method is designed to lessen the likelihood of getting false positive findings because of all the tests that are run. To rule out the possibility of random effects due to multiple comparisons, the Bonferroni procedure was employed to guarantee that the observed group differences are strong and durable. The reliability of the statistical findings is guaranteed in this way. A significance criterion of $p < 0.05$ was established.

RESULTS

The results of the study provide a comparative analysis of the diagnostic accuracy of AI-assisted odonto-periodontal imaging versus that of dentists with different levels of expertise. The findings are presented in terms of diagnostic performance, highlighting the agreement between AI and human evalua-

tions relative to the established reference standard.

Table I provides an overview of dental health by analysing the total number of decayed teeth, enamel cavities, and dentin cavities. For the total number of decayed teeth, values range from a minimum of 0 to a maximum of 19, with a mean of 8.36 and a standard deviation of 4.83, indicating significant variation between cases. Enamel cavities show a lower mean of 2.64, with a range from 0 to 9 and a standard deviation of 2.75, suggesting less enamel involvement compared to dentin cavities. In the case of dentin cavities, the values are higher, with a mean of 5.73 and a maximum of 12, highlighting a more significant dental concern. The high standard deviations across all three categories reflect considerable diversity in the dental health status within the studied group.

TABLE I.

The average values of decayed teeth, enamel cavities, and dentin cavities

	Minimum	Maximum	Mean	Std. Deviation
Decayed teeth	.00	19.00	8.3636	4.82505
Enamel cavities	.00	9.00	2.6364	2.75478
Dentin cavities	.00	12.00	5.7273	2.87453
Valid N (listwise)				

Analysing the percentage distribution of the number of cavities detected by the participants reveals significant differences between professional categories: senior specialists, specialists, general dentists, and AI and data is represented below (tab. II).

TABLE II.

The distribution of the number of detected cavities cases among participant groups.

		Doctors				Total
		Senior specialist	Specialist	Dentist	AI	
Number of teeth cavities	0.00			5.0%		1.5%
	1.00		10.0%	10.0%		6.1%
	2.00		20.0%	5.0%		7.6%
	3.00			5.0%		1.5%
	4.00		5.0%	15.0%		6.1%
	5.00		10.0%	5.0%		4.5%
	6.00			10.0%		3.0%
	7.00	20.0%	5.0%	20.0%		13.6%
	8.00		15.0%	15.0%	33.3%	12.1%
	9.00		20.0%	5.0%		7.6%
	10.00	15.0%	10.0%	5.0%		9.1%
	11.00	15.0%	5.0%		16.7%	7.6%
	12.00				33.3%	3.0%
	13.00	15.0%				4.5%
	17.00	20.0%			16.7%	7.6%
	19.00	15.0%				4.5%
Total		100.0%	100.0%	100.0%	100.0%	100.0%

For senior specialists, a balanced distribution of detected cavities is observed, with notable peaks at 7 and 17 cavities (20% each). This indicates a moderate involvement in detecting more complex cases, along with a uniform distribution of the number of cavities among their patients.

In the case of specialist dentists, the distribution is more balanced, with a peak of 20% for 9 detected cavities. This suggests that these participants evaluated patients with a wide range of dental issues but did not identify all existing carious lesions.

General dentists stand out with a higher proportion of cases involving a significant number of detected cavities, such as 7 and 8 cavities (20% each). This may reflect greater expertise in identifying cavities or increased exposure to patients with severe dental issues.

The AI system recorded the highest proportion of cases with extreme values, such as 8 and 12 detected cavities (33.3% each). These results indicate an enhanced ability to detect the presence of carious lesions.

Overall, the distribution of the number of detected cavities varies significantly depending on the type of participant, suggesting differences in professional experience, clinical approach, or the specific patient population examined. These differences highlight the importance of professional context in analyzing clinical data.

The Chi-Square analysis conducted to assess the relationship between the number of detected cavities and the type of participant revealed a statistically significant association. The Pearson Chi-Square test yielded a value of 86.075, with 45 degrees of freedom and a significance value of .000, indicating a strong relationship between the variables and rejecting the null hypothesis that there is no connection between the doctors and the number of detected cavities. These results were confirmed by the Likelihood Ratio test, which produced similar values (86.846) and an identical asymptotic significance ($p = .000$) (tab. III).

TABLE III.

The relationship between the number of detected cavities and the type of participant.

	Value	df	Asymptotic Significance (2-sided)
Pearson Chi-Square	86.075a	45	.000
Likelihood Ratio	86.846	45	.000
No. of Valid Cases	66		
64 cells (100.0%) have expected count less than 5. The minimum expected count is .09.			

A comparative evaluation of the average values of detected decayed teeth based on the participant groups was conducted (tab. IV).

Senior specialists had the highest average number of detected decayed teeth, 12.75, indicating significant involvement in evaluating more complex cases. The variability within this group is relatively high, with a standard deviation (SD) of 4.31, and the 95% confidence interval for the mean ranges from 10.73 to 14.77. The minimum number of decayed teeth detected in this group is 7, while the maximum is 19, indicating a wide range of case severity.

Specialists, on the other hand, recorded a

lower average number of detected decayed teeth, at 6.10, with moderate variability (a standard deviation of 3.45) and a confidence interval of 4.49 to 7.71. The minimum number of detected decayed teeth in this group is 1, while the maximum is 11.

TABLE IV.
Comparative evaluation of the average number of detected teeth based on participant groups

	N	Mean	Std. Deviation	Std. Error	95% Confidence Interval for Mean		Minimum	Maximum
					Lower Bound	Upper Bound		
Senior specialist	20	12.750	4.31491	.96484	10.7306	14.7694	7.00	19.00
Specialist	20	6.1000	3.44735	.77085	4.4866	7.7134	1.00	11.00
General dentist	20	5.3500	2.87045	.64185	4.0066	6.6934	.00	10.00
AI	6	11.3333	3.32666	1.35810	7.8422	14.8244	8.00	17.00
Total	66	8.3636	4.82505	.59392	7.1775	9.5498	.00	19.00

General dentists registered the lowest average number of detected decayed teeth, at 5.35, indicating a lower focus on identifying multiple caries. Variability in this group is lower (a standard deviation of 2.87), with a confidence interval for the mean ranging from 4.01 to 6.69. Extreme values in this group range from 0 to 10, reflecting less severe cases compared to other categories.

In the case of AI, the average number of detected decayed teeth is high, at 11.33, compared to that of senior specialists. However, the small sample size for this group (N=6) limits the robustness of the conclusions. The standard deviation is 3.33, and the confidence interval for the mean ranges from 7.84 to 14.82. Extreme values in this group range from 8 to 17, suggesting a high severity level of the analyzed cases.

Overall, the average number of detected decayed teeth across all categories is 8.36, with a standard deviation of 4.83, indicating significant variability between groups. The values range from 0 to 19 decayed teeth, with a confidence interval for the mean ranging from 7.18 to 9.55.

These results reflect the diversity of the analyzed cases and highlight the differences between groups in terms of professional experience and the types of patients evaluated.

The ANOVA test results show statistically significant differences in the number of detected decayed teeth among the participant categories. The high F-value (18.849) and $p < .001$ indicate that the type of participant has a significant effect on the number of detected decayed teeth. To better understand which groups, differ from each other, a post hoc analysis (e.g., Tukey test) would be useful to identify specific group pairs with significant differences.

TABLE V.
ANOVA test for identifying differences in detected caries among participant groups

Decayed teeth					
	Sum of Squares	**df**	**Mean Square**	**F**	**Sig.**
Between Groups	721.839	3	240.613	18.849	.000
Within Groups	791.433	62	12.765		
Total	1513.273	65			

The detection of enamel caries can be challenging, as they are often asymptomatic in the early stages and may require a combination of careful visual examination and detailed interpretation of radiographic images, such as orthopantomograms or periapical radiographs, to be accurately identified.

Descriptive analysis indicates significant differences between the participant groups (tab. VI).

TABLE 6**.**
Comparative evaluation of the average values recorded across groups.

	N	**Mean**	**Std. Deviation**	**Std. Error**	**95% Confidence Interval for Mean**		**Minimum**	**Maximum**
					Lower Bound	**Upper Bound**		
Senior specialist	20	4.7500	2.80741	.62776	3.4361	6.0639	.00	9.00
Specialist	20	1.5000	1.73205	.38730	.6894	2.3106	.00	5.00
General dentist	20	.8000	1.23969	.27720	.2198	1.3802	.00	5.00
AI	6	5.5000	2.25832	.92195	3.1300	7.8700	2.00	9.00
Total	66	2.6364	2.75478	.33909	1.9592	3.3136	.00	9.00

Senior specialists and AI reported the highest average number of cases (4.75 and 5.50, respectively), while specialist and general dentists recorded lower averages (1.50 and 0.80). The confidence intervals for the means of AI and senior specialists partially overlap, suggesting similarities in case detection. However, AI had the highest overall average and moderate variability, indicating greater consistency in reporting compared to senior specialists.

The dispersion of data varies significantly among the groups. Specialist and general dentists show low variability, indicating greater consistency in their results but also a possible underestimation of cases. In contrast, senior specialists exhibited a higher standard deviation (2.81), reflecting greater variability in caries detection. AI, with a standard deviation of 2.26, demonstrated relatively consistent detection, comparable to that of senior specialists in terms of maximum values.

Based on the minimum and maximum values, AI and senior specialists detected the most severe cases (up to 9 enamel caries), whereas specialists and general dentists reported a maximum of 5 cases. These findings suggest that AI and senior specialists are more sensitive in identifying extreme

cases, while specialists and general dentists tend to have a more conservative approach. The differences between groups highlight AI's potential to complement clinical diagnosis, especially in complex cases.

The ANOVA test results show statistically significant differences between the participant groups) (tab. VII).

TABLE VII.

Association of periodontal disease with the domicile of the patients

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	231.823	3	77.274	18.325	.000
Within Groups	261.450	62	4.217		
Total	493.273	65			

The F-value of 18.325 and the significance level of p=0.000 indicate that at least one group differs significantly from the others in terms of the average number of reported cases. The variability between groups (Sum of Squares = 231.823) accounts for a significant portion of the differences, while the within-group variability (Sum of Squares = 261.450) reflects individual variations within each group.

These results suggest that the observed differences are not random and confirm the existence of distinct reporting patterns among the groups. It is evident from the context that AI and senior specialists tend to report more cases, while specialists and general dentists have reported fewer cases.

DISCUSSION

The findings of this study highlight significant differences in the detection of carious lesions among the different participant groups, namely senior specialists, specialists, general dentists, and AI-assisted diagnosis.

Senior specialists and AI reported the highest number of detected carious lesions, suggesting that experience and technological support play a crucial role in caries detection. AI's ability to consistently identify carious lesions with high accuracy can be attributed to its advanced image processing algorithms and pattern recognition capabilities, which minimize the risk of oversight commonly encountered in human evaluations.

General dentists and specialists reported a lower number of detected lesions, potentially due to differences in diagnostic approach, reliance on clinical examination, and familiarity with radiographic analysis. The statistical analysis revealed a significant difference between these groups, emphasizing the variability in diagnostic accuracy based on professional experience and specialization.

The AI system exhibited a high level of consistency, with a relatively low standard deviation in the number of detected caries. This suggests that AI offers a standardized approach to diagnosis, reducing inter-observer variability that can arise in human assessments. Furthermore, AI's ability to detect caries in their incipient stages allows for earlier intervention, potentially improving long-term oral health outcomes and reducing the need for extensive treatments.

Consistent with our findings, recent research has thoroughly investigated the use of artificial intelligence (AI) for the identification and diagnosis of dental cavities. Khanagar *et al*. (15) conducted a comprehensive evaluation of artificial intelligence (AI) models developed for the purpose of

detecting, diagnosing, and predicting dental caries. Researchers found that by incorporating these models into clinical practice, diagnostic accuracy and patient outcomes might be significantly improved.

Also, Al-Khalifa *et al.* (16) reviewed the literature on dental caries and found that AI might be a useful tool for detecting the condition early and accurately. Deep learning models, such as convolutional neural networks (CNNs), can interpret several imaging modalities to aid in the identification and diagnosis of dental caries more efficiently and accurately than conventional approaches, according to the reviewed research.

Furthermore, Frenkel *et al.* (17) conducted an external validation of an AI-based model for caries detection using dental photographs. The study demonstrated that the AI model could detect, classify, localize, and segment carious lesions with high diagnostic accuracy, indicating its potential utility in clinical settings

Despite the promising performance of AI in cavities detection, certain challenges persist. The reliance on high-quality radiographic images is essential for optimal AI performance, and variations in image quality may impact detection accuracy (18). Additionally, AI algorithms are limited by the data they are trained on, which may introduce bias if the training dataset lacks diversity (19).

The integration of AI into routine dental practice offers numerous benefits, including enhanced diagnostic accuracy, improved workflow efficiency, and better patient communication through visual representation of detected lesions (20, 21).

These studies align with our findings, underscoring the significant advantages of AI-assisted diagnostic tools in dental imaging, particularly in the detection of carious lesions. The integration of AI into dental practice offers the potential for earlier intervention, improved diagnostic accuracy, and enhanced patient outcomes.

However, AI should be viewed as a complementary tool rather than a replacement

for clinical judgment, with final treatment decisions remaining under the purview of dental professionals

CONCLUSIONS

The study underscores the potential of AI-assisted diagnosis in enhancing the detection of carious lesions, particularly in cases that may be challenging for human evaluators. Future research should focus on refining AI algorithms, expanding training datasets, and exploring the integration of AI with other diagnostic modalities to further improve diagnostic accuracy and clinical decision-making.

This study demonstrates the significant advantages of AI-assisted diagnostic tools in dental-periodontal imaging, particularly in the detection of carious lesions. The results highlight AI's potential to support dental professionals in achieving higher diagnostic accuracy, reducing variability, and ensuring earlier intervention for better oral health outcomes.

Despite its strengths, AI should be integrated into dental practices with caution, ensuring that it complements rather than replaces the clinical expertise of dental practitioners. Further advancements in AI technology, along with continued training for professionals, will be essential to fully harness its benefits and address its limitations effectively.

PROMISING BIOLOGICAL ACTIVITIES OF SESQUITERPENE LACTONES (Abstract): Sesquiterpene lactones (SQLs) are an important group of bioactive compounds that are usually found in the *Asteraceae* family, where they seem to be some of the most important constituents for defense against microorganisms. These secondary metabolites have a skeleton of 15 carbon atoms and are derived from farnesyl diphosphate. It is generally believed that they might present certain biological actions in humans. Some of these actions are worth extended research: anti-inflammatory, antitumor, antibacterial, antifungal, antinociceptive, antiulcer and hepatoprotective. It seems that the presence of the α-methylene-γ-lactone group is correlated with the existence of many pharmacological actions. Due to promising results on human cancer cell lines, the research was expanded to clinical trials investigating the antitumor potential. Sesquiterpene lactones inhibit the expression of the nuclear factor kappa-light-chain-enhancer of activated B cells, which could explain the anti-inflammatory effect. They also have good activity against Gram positive bacteria. As a result, some of these compounds show promise for practical use in the treatment of cancer, different inflammatory diseases and even as antibacterial or antifungal agents, while some have already been introduced in therapy as antimalarial agents (artemisinin and its semisynthetic derivatives). However, more studies regarding their biological activities and toxicity mechanisms are still to be done. **Keywords:** SESQUITERPENE LACTONES, BIOLOGICAL ACTIONS, ANTITUMOR, ANTI-INFLAMMATORY.

INTRODUCTION

Medicinal plants have always been an important source of therapeutic agents, having a large variety of pharmacological activities (1). Nowadays, it is estimated that secondary metabolites extracted from plants still play an important role in the production of medicines and dietary supplements, covering around half of their total number (2, 3). Taking into consideration the need for discovering new agents for existent diseases, more and more researchers are focusing on the plant kingdom in the hope of discovering new efficient treatments or confirming new actions described by traditional medicine (4).

Around 30,000 compounds have been classified as terpenoids, which show a remarkable role in the defense mechanism of the plant. Many of these exert various biological actions and are currently used in the pharmaceutical industry, which explains the constant search for new similar structures and the tests carried out for dif-

ferent types of activities (3). Some terpenoid compounds represent constituents of volatile oils that produce the specific aroma of plants (4).

Sesquiterpenes are an important and complex group of natural terpenoids, in which have been included around 11,000 structures, with almost half of them representing the subclass of sesquiterpene lactones (5).

They are biosynthetically derived from farnesyl diphosphate and their name is related to the chemical structure, which contains a 15-carbon atoms skeleton formed by three isoprene units. Sesquiterpenes may or may not contain cycles in their structure, which leads to the following classification: acyclic, monocyclic, bicyclic, tricyclic and tetracyclic sesquiterpenes (3).

Sesquiterpene lactones (SQLs) represent a highly diversified group of bioactive compounds that can be found almost exclusively in the *Asteraceae* family, but have also been identified in species belonging to the other families such as *Cactaceae* and *Solanaceae* (2, 6). These compounds are stable secondary metabolites with bitter taste and a relatively high lipophilicity, lacking color (7). They are components of the plant latex, showing good antibacterial activity, but can also be synthetized in other types of cells, especially in case of plant injury (6). Sesquiterpene lactones can be extracted with different solvents, such as methanol, acetonitrile, n-hexane, chloroform and dichloromethane or by using supercritical carbon dioxide (8). The analysis of this type of compounds can be made using chromatographic methods, such as High-Performance Liquid Chromatography (HPLC) and Thin-Layer Chromatography (TLC) or hyphenated methods, such as HPLC-UV and Gas Chromatography-Mass Spectrometry (GC-MS) (9, 10).

Sesquiterpene lactones can be classified according to their carbocyclic skeleton in germacranolides, which represent the largest group and are precursors for other types of SQLs, guaianolides, pseudoguaianolides, eudesmanolides, eremophilanoides and hypocretenolides (6, 7).

Supposedly, SQLs present certain therapeutic actions in humans and some of these, including the anti-inflammatory, antitumor, antibacterial, antiprotozoal, antinociceptive, antiulcer and hepatoprotective properties, are currently being investigated (2, 6, 11). Some compounds derived from artemisinin, thapsigargin and parthenolide have already been included in cancer clinical trials, given their significant cytotoxic activity (7). However, new studies have revealed other potential activities of this type of compounds (e.g. histamine H1 receptor antagonism in the gut), proving the importance of research on sesquiterpene lactones (12). However, SQLs might be responsible for a series of conditions in humans, such as contact dermatitis, and could also present genotoxic activity, reproductive toxicity and teratogenesis (13, 14).

ANTITUMOR ACTIVITY

It is believed that three major characteristics are responsible for the antitumor and anti-inflammatory activities of SQLs: alkylating properties, high lipophilicity which facilitates the passage through membranes and conformational flexibility (7). Research has shown that the α-methylene-γ-lactone moiety is of major importance regarding most biological actions exerted by these compounds (15). This structure reacts with nucleophilic groups, such as sulfhydryl groups that can be found in enzymes and proteins, leading to the disruption of different functions (2, 13). Therefore, certain SQLs have the capacity

of modifying the redox state, inducing oxidative stress and apoptosis in cancer cells in a relatively selective manner (5).

There are several ongoing cancer clinical trials in which SQLs are investigated as potential antitumor agents. Artesunate, a well-known antimalarial drug, is being investigated regarding its safety and efficiency in stage II/III Colorectal Cancer (ClinicalTrials.gov Identifier: NCT02633098), as treatment in patients with cervical dysplasia (ClinicalTrials.gov Identifier: NCT02354534) and as treatment of HPV-associated anal intraepithelial neoplasia (ClinicalTrials.gov Identifier: NCT03100045). A phase one study was also conducted to evaluate its safety and pharmacokinetic properties when administered orally in patients with advanced hepatocellular carcinoma (ClinicalTrials.gov Identifier: NCT02304289). Artemether, which is currently used to treat malaria, has also been included in a phase 1/2a study that will assess its potential use in treating cancer (ClinicalTrials.gov Identifier: NCT02263950). Another phase II trial studies how well a thapsigargin prodrug works in treating patients with recurrent or progressive glioblastoma (NLM Identifier NCT02067156) (16). The activity of some SQLs has been examined on cancer cells, revealing potential benefits in different types of cancer (tab. I).

TABLE I.
Examples of Sesquiterpene Lactones and Their Anticancer Activity Based on Research on Human Cell Lines

SQL	Type of human cancer cell line	Reference
Parthenolide	Multiple myeloma cell lines	17
	Colorectal cancer cells	18
	Non-small cell lung cancer cells	19
	Pancreatic cancer cells	20
	Cervical cancer cells	21
	Osteosarcoma cancer cell	22
	Bladder cancer cells	23
	Breast cancer cell line	24
	Prostate cancer cell lines	25
	Melanoma cells	26
	Leukemic monoblastic U937 cell line	27
Costunolide	Osteosarcoma cells	28
	Esophageal cancer cells	29
	Colon cancer cell	30
	Lung squamous carcinoma cells	31
	Breast cancer cells	32,33
	Prostate cancer cells	34
	Ovarian cancer cells	35
	Promonocytic leukemia U937 cells	36
Alantolactone	Lung Squamous Cancer Cells	37
	Breast cancer MDA-MB-231 cells	38
	Colorectal cancer cells	39
	Hepatoma cells	40
	Leukemia HL-60 cells	41
	Human glioblastoma cell lines	42

ANTI-INFLAMMATORY ACTIVITY

It is believed that SQLs can prevent the production of mediators involved in the inflammatory response, therefore modulating functions present in both acute and chronic inflammation (43).

The Nuclear Factor kappa-light-chain enhancer of activated B cells (NF-κB) represents a protein complex that plays an important part in a series of processes such as inflammation, immune regulation, cell death and proliferation (44). However, it is involved in pathological processes as well, given the fact that it controls some mechanisms through which apoptosis and metastasis develop (6). Normally, NF-κB can be found in the cytoplasm tied to its inhibitory subunit (IκBα). The existence of proinflammatory stimuli leads to the activation of IκB kinase, which causes the release of NF-κB from IκBα and its displacement into the nucleus, where it initiates the transcription of genes associated with inflammation (43). Therefore, the inhibition of this transcription factor by SQLs could reduce the inflammatory response and block the multiplication of tumor cells (6).

Nevertheless, the inhibition of 5-lipoxygenase and cyclooxygenase has also been considered as another possible mechanism of action. For example, rudbeckolide from *Rudbeckia hirta* and ziniolide from *Xanthium spinosum* show good inhibitory activity on these enzymes (45, 46).

ANTIBACTERIAL AND ANTIPROTOZOAL ACTIVITIES

To resist the attacks of fungi, bacteria and viruses, plants can produce several chemical substances, such as phenolic compounds, tannins, alkaloids and terpenoids (4). In the *Asteraceae* family, sesquiterpene lactones seem to be some of the most important constituents for defense against microorganisms (6).

The antimicrobial activity of these secondary metabolites is correlated with the presence of the α-methylene-γ-lactone functional group and of a double α, β-unsaturated carbonyl group. It is assumed that SQLs induce alteration of the phospholipidic wall of membranes and modifications of protein synthesis (47).

Sesquiterpene lactones seem to have a better activity against Gram positive bacteria than against Gram negative bacteria (48). Examples of sesquiterpene lactones with good antibacterial activity include alantolactone and isoalantolactone, which are active against *Staphylococcus aureus*, but also on *Mycobacterium tuberculosis* (48, 49). A study focusing on germacranolide shows that parthenolide was the most active of the tested substances against both *Mycobacterium tuberculosis* and *Mycobacterium avium*. The same study highlights that the α-methylene-γ-lactone moiety, the presence of another alkylating site and a good lipophilicity seem to be responsible for the antimycobacterial activity (50).

Some of these secondary metabolites possess antiprotozoal activity, artemisinin being currently used as an antimalarial agent. Its discovery in the 1970s followed by clinical observations of its potent activity against *Plasmodium falciparum* led to its introduction in therapy along with other semisynthetic derivatives (4). It is believed that the compound acts in two phases. The intra-parasitic iron is thought to be responsible for the breakage of the endoperoxide moiety, followed by production of free radicals, which will eventually form stable bonds with the parasitic proteins (1).

SQLs are also active on other parasites such as *Trichomonas vaginalis* and *Entamoeba hystolitica* (51, 52).

ANTIFUNGAL ACTIVITY

Sesquiterpene lactones from *Centaurea thessala* and *Centaurea attica* have been investigated for their antifungal action, showing good activity against fungi from the *Aspergillus* and *Penicillium* genera (53). A study that included 36 SQLs emphasized the good antifungal activity of some SQLs such as dehydrozaluzanin C, dehydrocostus lactone, costunolide and zaluzanin C against *Colletotrichum acutatum* and *C. fragariae* (54).

In a research conducted by Picman, almost half of the 45 sesquiterpene lactones considered showed activity against *Microsporum cookei, Trichophyton mentagrophytes*, while only a few demonstrated activities against *Fusarium* spp., highlighting that eudesmanolides seem to be the most active (55). It was also proved that some guaianolides can inhibit the growth of *Candida albicans* (56). However, the research done to study the antifungal properties of this class of secondary metabolites is still insufficient.

CONCLUSIONS

Sesquiterpene lactones are a large class of constituents of the *Asteraceae* family with many potential therapeutic actions due to the α-methylene-γ-lactone group and other characteristic functional groups.

Some of these compounds show promise for practical use in the treatment of cancer, different inflammatory diseases or even as antibacterial agents, but extensive research on pharmacological actions and toxicity is still to be done.

BLOCK COPOLYMER-BORON CLUSTER CONJUGATE FOR EFFECTIVE BORON NEUTRON CAPTURE THERAPY OF SOLID TUMORS

The cancer is considered a major health problem worldwide and a big socio-economic burden which increases day by day. The mainstream treatment modalities in treating this disease are surgery, chemotherapy and radiotherapy. Boron neutron capture therapy (BNCT) is a selective tumor radio-therapeutic technique which is emerging as a hopeful tool in treating of cancer. This method is based on the administration of 10B-compounds in selectively tumor tissues and further thermal neutron irradiation of these to kill the cancer cells. Until now, the boron derivatives of sodium borocaptate and borophenylalanine presented an important potential for cancer therapy, especially in the cases where the traditional methods are difficult to be applied. In this study, the authors developed new block copolymer boron cluster conjugates, using sodium borocaptate (BSH) and poly(ethylene glycol)-b-poly(glutamic acid) copolymer in order to obtain a safe and efficient boron neutron capture therapy (an homogenous delivering of the boron clusters into the tumor cells and an effectively penetration in cancer tissues). The both synthetized conjugates showed a high cellular uptake by cancer cells and a high tumor accumulation, the most important elements for an efficient BNCT. The PEGylated BSH-polymer conjugate demonstrated a better profile in comparison with the non-PEGylated one. The obtained results are promising in the cancer therapy using PEG-modified clusters to develop new drug delivery systems (Mi P, Yanagie H, Dewi N, Yen H-C, Liu X, Suzuki M, Sakurai Y, Ono K, Takahashi H, Cabral H, Kataoka K. Block copolymer-boron cluster conjugate for effective boron neutron capture therapy of solid tumors. *Journal of Controlled Release* 2017; 254: 1-9).

COLORECTAL CANCER: A SMALL REVIEW OF CURRENT AND FUTURE MOLECULAR SCREENING MARKERS AND THE FIRST STEPS TO PERSONALIZED MEDICINE

A. Chirca[1,2], R. V. Costea[1,2*], Florentina Ligia Furtunescu[1], Dana Galieta Minca[1]

COLORECTAL CANCER: A SMALL REVIEW OF CURRENT AND FUTURE MOLECULAR SCREENING MARKERS AND THE FIRST STEPS TO PERSONALIZED MEDICINE (Abstract): Colorectal cancer is the third most common cancer, the fourth cause of death globally and represents 9.4% of all incident cancer in men and 10.1% in women, with high incidences reported in North America, Oceania and Europe, and low incidences in Asia and Africa. The improved prognosis in the past decades, and a 5-year survival rate which exceeds 65% in developed countries, demonstrate that colorectal cancer is a curable disease. Colorectal cancer is a very heterogeneous condition, in which early diagnosis and specific treatment project it in the curable area of disease, therefore a screening process must ensure effectiveness in reduction of disease mortality and cost. Serological markers have some limitations, but molecular markers, that explore chromosomal and microsatellite instability and mutations, are gaining ground to become the golden standard and will lead the way in new screening methods and personalized medicine guidelines. A major future challenge for all cancer biomarkers will be the integration of pharmaco-genomics, proteomics and metabolomics functional data, with epidemiological and clinical data. **Keywords**: COLORECTAL CANCER, MOLECULAR MARKERS, SINGLE NUCLEOTIDE POLYMORPHISM, PERSONALIZED MEDICINE.

Colorectal cancer is classified as the third most common cancer and the fourth cause of death globally, accounting for roughly 1 to 2 million new cases and 600,000 deaths per year in the USA (1-3). Although it's incidence is low at ages younger than 50 years, median age at diagnosis is about 70 years in developed countries (4). Worldwide colorectal cancer represents 9.4% of all incident cancer in men and 10.1% in women, however, it is not uniformly common throughout the globe with different populations experiencing different incidence rates, with high incidence reported in countries from North America, Oceania and Europe, and low incidence in countries of central Asia and Africa (5, 6). With improved, slow but steady, prognosis in the past decades, and a 5 year survival rate that exceeds 65% in developed countries, colorectal cancer is being seen as a curable disease with new molecular technologies used in prediction, diagnosis, and recurrence risk (4, 7-9). Unlike other types of cancer, no single risk factor can be pinpointed as having a high

prevalence, and a combination of multiple factors are highlighted in epidemiological studies. Of those cited we remind family history of colorectal cancer (10), diabetes (11), inflammatory bowel disease (12), smoking (13), excessive alcohol consumption (14), obesity (15), and high consumption of red and processed meat (16). The risk increase is strongest for people with first-degree relatives with colorectal cancer (those with relatives diagnosed at young ages or multiple affected relatives) and people with inflammatory bowel disease, and according to a large twin study, 34 35% of colorectal cancer risk may be attributed to heritable factors (17). Apart from hereditary forms, such as hereditary non-polyposis colon cancer like Lynch syndrome and familial adenomatous polyposis, which are understood as being determined by well-known genetic aberrations, that represent less than 5% of all colorectal cancer, genetic risk determining factors are still not yet understood (18). It is believed that the cause of colorectal cancer may lie in a cascade of genetic mutations that describes the adenoma-carcinoma sequence, in which normal epithelial mucosa gradually progresses to adenoma and then to carcinoma as a direct result of these changes (19, 20). Increased screening would most likely result in cost savings to the healthcare system, since more CRCs would be detected at an earlier stage and newer, more expensive chemotherapies could be avoided (21).

Molecular pathogenesis

Colorectal cancer molecular pathogenesis is very heterogeneous and it result is the loss of genomic stability , which needs to be understood if prognosis and treatment response are to be optimal (22-25). Several forms of genetic instability have been identified and include epigenetic gene instability, microsatellite instability(MSI), and chromosomal instability(CIN), of which the ladder includes 80-85% of all colorectal cancers through oncogene activation and loss of heterozygosity of tumor suppressor genes, and it is suggested that chromosomal instability induces carcinoma through the mutation or loss of the TP53 and APC genes, and activation of the KRAS, with a poor prognosis (19, 26, 27).

Microsatellite instability

Representing about 15% of CRC, microsatellite instability consists of deletions and insertions of short repetitive DNA sequences in a given gene, a consequence of DNA mismatch repair deficiency, where 3% of these are associated with Lynch syndrome and the other 12% are caused by sporadic, acquired hypermethylation of the promoter of the MLH1 gene, which occurs in tumors with the CpG island methylator phenotype (19, 28, 29). Although any single MSI in a gene may not have a significant subclinical or clinical impact, their accumulation can give rise to tumor progression.(19) They are frequently found in tumor suppressors such as activin receptor type 2 (83%) and transforming growth factor βR2 (69%) (19). MSI has a significant impact on tumor biology and is reflected by a more favorable prognosis of this molecular CRC subtype and a lacking response of MSI-H CRCs to 5`fluorouracil monotherapy (30). MSI status is determined in poorly differentiated cancers according to conventional histologic grading.

Epigenetic gene silencing

All stages of tumor formation to progression have been associated with chromatin alteration consisting in DNA methyla-

tion. Cancers that present a great degree of DNA methylation can be considered CpG island methylation phenotype (CIMP)(31). In normal cells CpG islands are found in regions close to promoters, and if there is an aberrant hypermethylation tumor suppressor genes can be sliced repressing gene expression (19, 31, 32). Reversing gene silencing may be useful in cancer prevention and therapy.

Genome-wide association studies

Genome-wide association studies (GWAS) have evolved over in the last years into a powerful tool for investigating the genetic architecture of human disease (33). They analyze and measure the variation in the genome's DNA sequence to identify genetic disease risk factors that are common in each population and rely on the identification of SNPs. The modern unit of genetic variation is the single nucleotide polymorphism or SNP. SNPs are single base-pair, high frequency occurring changes in the human DNA genomic sequence (34).

SNPs

They are best described as a variation at a single position in a DNA sequence of four nucleotide bases: A, C, G, and T. If more than 1% of a population does not carry the same nucleotide at a specific position in the DNA sequence, then this variation can be classified as a SNP(35). If a SNP occurs within a gene, then the gene is described as having more than one allele in which case, SNPs may lead to variations in the amino acid sequence. However, SNPs, are not just associated with genes as they can also occur in noncoding regions of DNA.

Most SNPs have no effect whatsoever on health and development, but some of these genetic differences, however, have proven to be quite important in the study of human health. SNPs may help predict the individual's response to certain drugs, susceptibility to environmental factors, and risk of developing a particular disease. SNPs can also be used to track the inheritance of disease genes within families. Typically SNPs are used as *markers* of a genomic region, relatively even distribution in the human genome, with the large majority of them having a minimal impact on biological systems but can have functional consequences especially it they are found in coding regions (36-38). SNPs are increasingly becoming the DNA marker system of choice due to their prevalence in the genome and their ability to be used in highly multiplexed genotyping assays.

Identifying genes involved in the development of cancer is crucial to fully understand cancer biology, for developing novel therapeutics for cancer treatment and for providing methods for cancer prevention and early diagnosis. The use of polymorphic markers, in particular single nucleotide SNPs, promises to provide a comprehensive tool for analyzing the human genome and identifying those genes and genomic regions that contribute to the cancer phenotype (9, 39).

Whole genome sequencing

Today whole genome sequencing is the best method to obtain all an individual's genetic information, practically drawing a comprehensive genetic map, and even though the cost of sequencing is constantly falling, new technological advancements are required to make this method a cost-effective screening process

Clinical application of molecular markers

Many CRC remain asymptomatic years

before they are diagnosed due to the time needed for the genetic mutation to take place. CRC has two gastrointestinal tumor markers used for screening carcinoembryonic antigen (CEA) and carbohydrate antigen (CA). Although elevated levels are associated with disease progression, they can be under the detection range until advanced disease stages are present, and postoperative they are important in disease recurrence.(40). Molecular markers have the advantage that they can be an early warning system not only raising awareness, but by their non-invasive nature be more appealing with a far greater compliance than standard screening methods such as colonoscopy and fecal occult blood test(FOBT).They can encourage more patients to undergo screening, and could significantly decrease CRC mortality.

Current molecular markers used in diagnosis

CIN markers include the RAS family inner surface plasma membrane protein encoders (HRAS, NRAS, KRAS) of which KRAS plays the leading role(26). It encodes GTP binding proteins that act like molecular switches, inactivating intracellular signal transducers for surface receptors such as EGFR (epidermal growth factor receptor), being an intracellular downstream component of the EGFR signaling cascade. Once activated the RAS gene suppresses apoptosis and promotes cell survival. From an oncogenic point of view the RAS family mutation is an early CRC event and as many as 37% of CRCs and 50% of adenomas larger than one centimeter exhibit this mutation(27). In 2008, exclusion of KRAS hot spot mutations in exon 2 has become mandatory for the application of EGFR-targeting antibodies in the first-line therapy of advanced colon cancer. The list of genetic alterations to be excluded for EGFR antibody therapy has been extended to KRAS exons 3,4 and NRAS exons 2–4 in 2013 after no responsiveness has also been found for these alterations(41). Other genetic changes like BRAF and PI3K mutations have been described to be associated with no, to some, EGFR antibody response, but the data generated in a different study is too controversial to include these markers in routine predictive molecular testing and therapy decision making(41-43). It is foreseeable, however, that the number of markers predicting therapy response in CRC will rise with new data being generated from larger CRC cohorts.

MSI markers identification relies on two main methods of detection that highlight genetic mechanism causing the disease, and are represented by polymerase chain reaction (PCR) and immunohistochemistry. MSI-H is a trademark alteration of hereditary nonpolyposis colon cancer (HNPCC)/Lynch syndrome-associated tumors, but is also found in sporadic colon cancers (44, 45). With the revised Bethesda guidelines in mind, colon cancer is tested for MSI to evaluate the possibility of Lynch syndrome (46). In combination with immunohistochemical analysis of the mismatch repair proteins (MLH1, MSH2, PMS2 and MSH6) and EPCAM40 the molecularly determined MSI status is the first step in genetic determination and counseling. Among the tested regions, when MSIs are present in two or more regions, the tumor is classified as MSI-High, otherwise, the tumor is considered as MSI-Low (MSI in one region) or MSI-Stable (no MSI) (28).Only in the absence of MSI-H, histological poor /high-grade differentiation (G3–4) is considered a prognostic marker while MSI-H cancers are considered low

grade(41).

Plasma methylated Septin 9 (SEPT9) DNA is a marker of colorectal cancer(3). SEPT9 gene encodes the Septin 9 protein, which is a member of GTP-binding proteins that involves in many cellular processes such as cell cycle (47, 48). Disruption of SEPT9 gene could result in tumor formation. In comparison with normal individuals the biomarker septin-9 has been found to be hyper methylated in nearly 100% of tissue neoplasia specimens and detected in circulating DNA fractions of CRC patients(49). In a study of 8000 patients that underwent routine screening colonoscopy, blood was collected and the results from the septin-9 test were compared to those of colonoscopy with a 67% CRC detection rate and 11% false positive rate (47). It is a sensitive screening test that can detect the majority of CRC, and can be combined with colonoscopy to ensure (50) .

In the past few years GWAS have found some heterogeneity in colorectal cancer risk, and many polymorphisms have been showed to have a link in risk assessment, early diagnosis, evolution, and recurrence of CRC. As databases like SNPedia or DBsnp are continuously updating, there isn't yet a SNP or SNPs that can make up a screening panel that will have a good sensibility and specificity. Although studies have shown an association between the presence of a certain SNP and CRC there is still little data that can standardize a single nucleotide polymorphism to a given condition, and with hole genome sequencing still at an excessive cost, modern technology is needed to ensure a cost-effective reliable method

CONCLUSIONS

Colorectal cancer is a very heterogeneous condition in which early diagnosis and specific treatment project it in the curable area of disease, therefore a screening process must ensure effectiveness in reduction of disease mortality and cost. Serological markers like CEA and CA, have some limitation and in many cases unreliable in early detection, as well as imaging and invasive methods where the patient's compliance is key. Molecular markers that explore chromosomal and microsatellite instability as well as other mutations are steadily gaining ground and will most likely be the golden standard soon an open mind must be had and focused placed on molecular markers which show a great promise and will lead the way in new screening methods and personalized medicine guidelines.

Also, with every human genome sequenced and analyzed more and more information is gained and if the evolution of technology and cost is constant, hole genome sequencing will be the only screening test an individual will have to do. A major future challenge not only for CRC, but for cancer biomarkers in general will be the integration of pharmaco-genomics, proteomics and metabolomics functional data, with epidemiological and clinical data (51).

PHENOTYPIC VARIABILITY IN EDWARDS SYNDROME (Abstract): Edwards Syndrome is the second most common autosomal trisomy syndrome after trisomy 21, with a liveborn prevalence of 1/10,000. ES is characterized by variable clinical manifestations, with involvement of multiple organs and systems. ES is produced by trisomy 18, and most cases present a complete and homogeneous chromosomal aneuploidy. **Aim:** To identify the clinical suggestive features of ES. **Material and methods:** We performed in Iasi Medical Genetics Center a retrospective study on 12 years (2003-2015) and we discovered 19 patients with trisomy 18. **Results:** 18 patients had a complete trisomy and 1 case presented a partial trisomy. The frequent clinical features were: intrauterine growth retardation, micrognathia, dysplastic ears, dolichocephaly, heart defects, prominent calcaneus, overriding fingers and preterm birth. Also, we identified an increased frequency of caesareans procedures. The common visceral anomalies were cardiac and most frequent such anomalies were: ventricular septal defect and patent ductus arteriosus. Other visceral anomalies were: horseshoe kidney, esophageal atresia and hydrocephalus. Breech presentation was a common feature. **Conclusions:** Edwards syndrome is suspected in patients with the associations of the following features: growth retardation, typical craniofacial dysmorphism, heart defects, prominent calcaneus, overriding fingers and preterm birth. Gastrointestinal and renal anomalies are common features. **Keywords**: EDWARDS SYNDROME, 18 TRISOMY, GROWTH RETARDATION, CRANIOFACIAL DYSMORPHISM, HEART DEFECTS.

Edwards syndrome (ES) is caused by trisomy 18, the second most common autosomal trisomy syndrome after trisomy 21 (1). The first reported cases were described in 1960 by Edwards *et al* and Smith *et a*l (2, 3). ES pregnancies have a high risk of fetal loss and stillbirth, so overall prevalence (1/2,600) is higher than liveborn prevalence (1/10,000) (4). The probability of survival to term increases with the increase of gestational age: 28% at 12 weeks, 35% at 18 weeks and 41% at 20 weeks (5). The prevalence at birth is higher in females compared to males (♀:♂

= 6:4) due to higher rate of fetal loss in males (6).

The cytogenetic changes in ES are: homogeneous complete trisomy (94% of cases), mosaics (about 5% of cases) or partial 18q trisomy (about 1% of cases) (7). The extra chromosome 18 has in majority of cases a maternal origin, being generated by a meiotic non-disjunction. About 50% of the maternal errors occur in meiosis II, unlike other human trisomies where the malsegregation is more frequent in meiosis I. The frequency of non-disjunction increases with advancing maternal age. In the rare cases with paternal origin, the extra chromosome is the result of a postzygotic error (8-11).

ES is a plurimalformative syndrome whose main features are: prenatal growth deficiency, characteristic craniofacial features (dolichocephaly, short palpebral fissures, micrognathia, dysplastic ears), distinctive hand posture (clenched fists with overriding fingers), nail hypoplasia, posterior prominence of calcaneus (rocker-bottom foot), short sternum and visceral major malformations (particularly cardiac) (12). The phenotype is variable: more than 130 different anomalies have been reported in the literature, which may affect all organs and systems (13, 14).

MATERIAL AND METHODS

We made a clinical and cytogenetic retrospective study on a group of 19 cases of ES. The cases were identified between 2003 and 2015 in Iasi Medical Genetics Center and all were confirmed by chromosomal analyze.

RESULTS

In our group 11 patients were males and 8 females (♂:♀ = 1.37). The most frequent clinical features (tab. 1) were: intrauterine growth retardation (IUGR) (19 cases), cranial dysmorphism (fig. 1) with micrognathia (19 cases), dysplastic ears (19 cases), dolichocephaly (18 cases), heart defects (18 cases), prominent calcaneus (17 cases) (fig. 2) overriding fingers (13 cases) (fig. 3) and preterm birth (13 cases). An increased frequency of caesareans procedure was noticed (14 cases). The visceral congenital anomalies were represented by: cardiac (18/19 cases) gastrointestinal (8/19) renal (7/19) and centrals nervous system (5/19). The most common anomalies in descending order of frequency were: ventricular septal defect (12 cases) patent ductus arteriosus (11 cases), horseshoe kidney (4 cases), esophageal atresia (4 cases), hydrocephalus (4 cases) pentalogy of Fallot (3 cases) and Meckel diverticulum (3 cases).

The obstetrical history revealed IUGR (all cases) associated with polyhydramnios in 5 cases. Breech presentation was noticed in 8 cases and a advanced maternal age was found in 6 cases.

The prognosis was bad in majority of cases. From 16 patients with known period of survival 10 died in first month of life, 5 lived longer than 1 month and only one girl survived beyond the first year.

Clinical diagnosis was confirmed by chromosomal analysis in all cases: a complete and homogeneous 18 trisomy (fig. 4) – 47,XX(XY),+18 (18/19 cases) and a partial 18 trisomy associated with a complex abnormality
46,X,Yqh+,1qh+,+18,der(13;18)
(q12;p11.2) (fig. 5) (1 case). The patient (C19) with complex abnormality (partial 18 trisomy and a very small partial 13 monosomy) had suggestive features of ES and diaphragmatic hernia.

DISCUSSION

ES is characterized by variable clinical manifestations, with involvement of multiple organs and systems. There are key features present in patients, but there is also a wide heterogeneity of clinical manifestations. Some features overlapping with other syndromes can sometimes complicate the diagnosis. To facilitate accurate diagnosis, we tried to identify the most suggestive combinations of clinical features.

IUGR is one of the most frequent finding in ES; the mean birth weight is 1700-1800 g at a mean gestational age of 37 weeks (15). The study of Kroes *et al* also confirms that IUGR is a specific prenatal feature of trisomy 18, feature that is not characteristic for trisomy 13 (17). In our study IUGR was present in all cases, consistent with literature data. The growth deficiency continues after birth for all major anthropometric parameters – weight, height and cranial circumference – but with major implication on the weight (18). Gastrointestinal anomalies and orofacial clefts may contribute to feeding problems (13).

The triad of craniofacial features: prominent occipital bone, low-set, dysplastic ears ("faun ears") and micrognathia was highly suggestive for ES (18/19 cases). Rosa *et al* in a study on 50 patients reported as main craniofacial abnormalities: micro retrognathia (76%), abnormalities of the ear helix/ dysplastic ears (70%) and prominent occipital bone (52%) (19). Cleft lip/palate was present in 3/19 of our cases (one bilateral form, one unilateral form and one palate cleft). Our result is like literature data; orofacial clefts are considered a less frequent (5-25%) anomalies in ES (1, 12, 18), but is more frequent associated with trisomy 13: 60-70% (20-21).

Previous studies show that 80-100% of ES patients have congenital heart defects (CHD); the most common cardiac anomalies are ventricular and atrial septal defects (VSD, ASD), patent ductus arteriosus (PDA) and polyvalvular disease (13, 22, 23). We found a similar situation and we identified heart defects in 18/19 of cases. VSD (12/18) and PDA (11/18) were the most common cardiac anomalies. Other detected CHD were: ASD (4/18), polyvalvular disease (4/18), pentalogy of Fallot (3/18), coarctation of aorta (2/18), anomalous origin of coronary arteries (2/18), bicuspid aortic valve (2/18), single ventricle (1/18), dextrocardia (1/18). The complex heart defects were detected in 3/19 of cases, like literature data (10%) (13).

In our study, 17/19 of the patients had prominent calcaneus ("rocker bottom foot"). This abnormality has also been reported in the literature as occurring from 48 to 90% of the cases (24, 25). Other features concerning the lower limb identified in our study were: syndactyly of the toes – 4 cases (I-II/II-III/III-IV cutaneous), short hallux – 3 cases, and clubfoot – 2 cases. In the literature, these findings are cited with a highly variable frequency (18, 24, 25).

The most frequent abnormality of upper limbs in our study was clenched fists with overriding fingers: 13/19 of cases. In other reports the frequency was from 58 to 96% of the cases (25-27). Many authors consider this feature one of the important diagnostic clues, and it is often detected sonographically in the prenatal period (especially in third trimester of pregnancy) (1, 13).

In the literature, a major malformation of limb occurs in 5-10% of patients, including radial aplasia and other preaxial limb defects (1, 18, 24). We detected the radial aplasia in one case and agenesis of the thumb in other case. Nail hypoplasia is cited in the literature with a highly variable frequency (13-63%) (24, 25). In our study this feature was detected in 10/19 of cases.

Gastrointestinal anomalies are cited among patients with ES. In the literature,

the frequency of esophageal atresia/ tracheo-esophageal fistula among the patients with trisomy 18 ranges from 16 to 20% (25, 28). In our study the frequency was similar 4/19. Omphalocele have been described in less than 10% of the cases, which is compatible with the rate in our study – 1/19 (18, 29). Meckel diverticulum was detected in 3 cases in our study, like literature data (less than 25%) (18). In our study the global frequency of gastrointestinal anomalies (42.10%) was higher than reported in the literature (less than 25%) (12, 18).

Horseshoe kidney (HK) is a common congenital anomaly of the kidney with a prevalence of 1 in 500 (30). HK is reported in 20-66% of patients with ES in the literature data (30, 18). In our study, only 4 cases had this anomaly. Other renal anomalies found by us were: renal hypoplasia – 1 case, duplication of ureter – 1 case and renal cysts – 1 case.

Several structural abnormalities of the central nervous system (CNS) have been reported in trisomy 18; the most frequent are cerebellar hypoplasia, agenesis of corpus callosum, hydrocephalus and myelomeningocele. These anomalies are present in about 5-25% of infants (1, 18, 26). CNS abnormalities detected in our study were consistent with literature data: hydrocephalus – 4 cases, agenesis of corpus callosum – 1 case and myelomeningocele – 1 case.

Yamanaka et al reported a higher preterm birth frequency (35%) compared to general population. In our study the frequency of preterm birth was even higher 68.42%. An increased incidence (64%) of caesareans has been reported (15). In our study 14/19 (73.68%) of patients were born by cesarean.

We found a sex ratio ♂:♀ of 1.37. This finding is discordant with other studies that showed a sex ratio of prenatally diagnosed cases of 1:1, but for the live-born sex ratio ♂:♀ was between 0.63 (Huether, 1702 cases) and 0.56 (Niedrist, 161 cases) (32, 33). This discrepancy could be related to small size of our study group.

Management of neonates with trisomy 18 is controversial, due to the bad prognosis (lethality and intellectual disability) and the lack of precise information concerning efficacy of treatment (1, 15, 16).

CONCLUSIONS

ES is a chromosomal syndrome with variable clinical features. The most suggestive clinical findings were: IUGR, typical craniofacial dysmorphism (dolichocephaly, dysplastic ears, micrognathia), heart defects, prominent calcaneus, overriding fingers and preterm birth. Gastrointestinal and renal anomalies are also common features. Early diagnosis is important for appropriate management decisions regarding neonatal care and invasive procedures.

CONSIDERATIONS OF PLATELET-RICH FIBRIN USE IN ORAL SURGERY (Abstract) Nowadays, tooth extraction has become a frequently performed surgical procedure whose most common postoperative outcome is alveolar bone atrophy. To reduce the bone dimensional changes, localized alveolar ridge augmentation or socket preservation with bone grafting is required. The socket may be filled with synthetic grafts, xenografts, autografts, allografts, autologous platelet concentrate. The use of platelet concentrates for healing improvement and regeneration of the soft and hard tissues in oral cavity is one of the latest achievements in dentistry. One of the newest practices in bone augmentation is the use of platelet rich fibrin, derived from the patient's own blood and can be very easily accepted by patients due to cost effectiveness, low donor morbidity and low rate of postoperative complications or infection. This biomaterial might be a solution for patients that have strong beliefs regarding the use of allografts or xenografts, or which are afraid of complications during or after autografting procedure. One cannot say that there is an ideal grafting material and must consider a person's religious affiliation or beliefs when performing bone augmentation. **Keywords:** PLATELET-RICH FIBRIN, ETHICS, BONE AUGMENTATION.

A.B., a dental implant patient, asks: For personal religious reasons, I do not want animal or human bone graft material to be placed in my body. I should do an extraction and my dentist says I will need a bone graft. Now, he cannot offer me a bone graft that does not include animal or human graft products. What are my alternatives? Thanks!

Nowadays, tooth extraction has become a frequently performed surgical procedure whose most common postoperative outcome is alveolar bone atrophy (1). Hard and soft tissue preservation following the extraction of one or more teeth is one of the most challenging objectives of dental procedures (2). Sufficient alveolar bone volume and favorable architecture of the bone are essential for aesthetic appearance, especially when anterior sites are involved, and for the placement of dental implants in a prosthetic ideal position. To reduce the bone dimensional changes, localized alveo-

lar ridge augmentation or socket grafting is needed (1, 2). The socket may be filled with (2, 3): Synthetic grafts (hydroxyapatite, tricalcium phosphate, etc.); Xenografts (bone substitute of animal origin, such as bovine or porcine bone); Autografts (bone harvested from the patients' own body - the donor site can be the menton region, retromolar area, maxillary tuberosity, iliac crest, calvarias, tibia (4)); Allografts (cadaveric bone, usually obtained from a bone bank); Autologous platelet concentrate (platelet-rich plasma, platelet-rich fibrin).

The use of platelet concentrates for healing improvement and regeneration of the soft and hard tissues in oral cavity is one of the latest achievements in dentistry (5). This platelet concentrates are obtained by centrifugation fresh venous blood drawn from the patient's vein (6). Platelet-rich plasma (PRP) is a first generation concentrate, the blood is collected with anticoagulant and needs chemical additives, such as Calcium Chloride and bovine thrombin to make gel condition (7). But the latest studies show that PRP has a low effect on hard tissue regeneration (8). Thus, a second-generation aggregate was introduced: platelet-rich fibrin (PRF). The blood is collected without any anticoagulant, immediately centrifuged and the PRF protocol doesn't need biochemical additives to make gel condition (6). The PRF clot is obtained through a natural polymerization process during centrifugation and its natural and stable fibrin architecture seems responsible for tissue regeneration (5). The PRF can be used as a filling material in extractions, alone or mixed with a bone substitute. As the number of available biomaterials increases, the doctor has the obligation to explain the nature, purpose and the benefit/risk ratio of a proposed bone grafting material. According to The General Medical Council, „when providing information, the physician must do his best to find out about patients' individual needs and priorities": religious affiliation and beliefs, culture or other factors that can influence his decision (9). Valid consent to treatment is therefore absolutely central in all forms of healthcare, from providing personal care to undertaking major surgery." The DoH states that "different patients will make different choices in apparently similar situations" (9).

Until now in Romania there hasn't been developed any standard informed consent form that specifies the type of biomaterial that is being used. The Romanian College of Dentists developed in 2013 a compulsory informed consent form for surgical procedures in the dental office, without making any reference to graft types and their origin. Therefore, providing a treatment plan without taking in consideration the ethical, legal or social implications, the treatment may not reflect the, best interest'of the patient. When using xenografts or PRP combined with bovine thrombin or autologous platelets concentrate which needs blood drawing, the doctor should know that certain religious groups have restraints regarding the dietary use of porcine and bovine products or don't accept blood products, limiting treatment options (10). When planning a bone augmentation, the doctor should bear in mind the religious beliefs, explain the surgical act, present the biomaterials that are being used and act accordingly.

One of the newest practices in bone augmentation is the use of platelet rich fibrin, derived from the patient's own blood and can be very easy accepted by

patients due to cost effectiveness, low donor morbidity and low rate of postoperative complications or infection. This technique might be an alternative to autografts, which are harvested from the patient's body, so the patient could avoid the postoperative evolution and possible complications: hematoma, edema, infection, vascular and nerve lesion, morbidity of the donor area and chronic pain (10). Up to 15% of patients having an iliac graft harvested have been complain of pain for more than 3 months in the donor site (10). Furthermore, the PRF technique obviates immunological reactions and the risk of disease transmission associated with allograft bone, taken from a tissue bank (11). Allografts are harvested from dead human donors, whose families have consented to tissue donation, respecting a certain protocol, but there is still a minimal risk of immunogenic reactions, transmission of disease from donor to recipient or recipient site infection given by a potentially contaminated product (12, 13).

Platelet-rich fibrin (PRF) was developed in 2001 in France by Prof. Dr. Joseph Choukroun (MD, Anesthesiologist, Private Practice, Pain Clinic Center, Nice, France) (14) and it has been used in Europe for the past decade. This biomaterial is being prepared by the surgeon, from the patients' blood and needs a very simple protocol. Oral surgeons have adopted this technique in their private dental practice and the PRF preparation requires an adequate centrifuge, 10 ml blood collection tubes (14), winged infusion sets, also known as „butterfly" sets for venipuncture and a PRF box kit. PRF is an autologous fibrin matrix rich in platelets, leucocytes and monocytes that induces a cascade of multiple growth factors release (15). It is a simple technique, blood is collected from the patient, centrifugated and the resultant product is formed of three layers (fig.1a): the top layer is represented by platelet poor plasma, in the middle is the platelet-rich-fibrin clot (fig. 1b), which it is used clinically and red blood cells at the bottom, that are easily discarded (16).

a.  b.

Fig 1. a. The resultant product and is formed of three layers: top is the PPP, middle is the PRF clot and bottom are the red blood cells; **b.** The PRF clot (personal cases)

To obtain a viable product for the patient's benefit and at the same time to assure his safety, the doctor must know and respect the PRF protocol, yet only a few

practitioners know it. It is known that PRF is derived from the patient's blood and no anticoagulant, no chemical additives, such as Calcium Chloride or bovine thrombin are used, thus is 100% natural to the patient. Because of the absence of an anticoagulant, blood begins to coagulate as soon as it encounters the glass surface (14), so the drawing must be fast. An important issue is the blood drawing, because the dental surgeon isn't trained in phlebotomy procedures. Therefore, when choosing for bone augmentation the PRF technique, the doctor must explain the procedure to the patient, and the reason for the blood sample being taken. Also, the patient should be informed about the complications or accidents of a phlebotomy: hematoma, edema, syncope or the doctor can't find the vein. Today, after long research, Choukroun et al. approved one type of centrifuge, with its own protocol: The PRF-Duo centrifuge. Surgeons should know that they can use this autologous product even in patients with anticoagulant therapy, but the time of centrifugation must be changed. The tubes that are used for collecting blood must be labelled with CE 0197, a certification of medical quality used by the European community, analogous to FDA certification in the United States (15). The blood drawing and the centrifugation represent only half of the PRF protocol. The other half is the handling of the PRF clot and properly preparing it for clinical use by using the PRF box kit. After centrifugation, the PRF must be extracted immediately from the tube. A tweezer is inserted into the tube, gently grab the fibrin clot with attached red blood cells and with a scissor cut through the RBC's (14, 15). The fibrin clot is transferred to sterile metal surface and the red blood cells are scraped away and discarded (fig. 2) (17).

Fig. 2. Handling of the PRF clot (personal cases)

The PRF box kit (fig. 3a) was created for the fabrication of plugs (fig. 3b) and membranes. PRF can be used as a plug, that contains a high concentration of platelets enmeshed in a fibrin matrix, which releases a high concentration of growth factors over a long time or as a fibrin membrane acting as a matrix to promote healing (18). The PRF Box is a necessary instrument used to automatically produce high qualities membranes of constant thickness and size (17).

a. b.

Fig. 3 a. The PRF Box (courtesy of Prof. J. Choukroun, France);
b. Obtaining PRF plugs, used in postextractional sockets (personal cases)

Clinically, the membrane displays excellent working properties. It is resilient, strong and pliable, making it easy to manipulate, cut and suture. When preparing membranes, the box recovers the exudate from the PRF clot that can be used in hydration of the biomaterial (17). Also, the PRF box it is useful during surgery to preserve the membranes. Essentially, the doctor should create the PRF by following a precise protocol for centrifuging a given quantity of the patient's blood so the results are in the interest of the patient. This biomaterial might be a response for patients that have strong beliefs regarding the use of allografts or xenografts, or which are afraid of complications during or after autografting procedures. Using this technique, it is imperative that surgeons understand the indications and limitations of the PRF and they must know the proper protocol for PRF synthesis. We cannot say that there is an ideal grafting material and we must consider that bone augmentation must be carried out accordingly to everyone's beliefs.

CONCLUSIONS

Platelet-rich fibrin, unlike other methods of bone augmentation, is entirely autologous and there are limited ethical concerns and no toxicity implication related to this stable and natural blood clot and therefore should be included in the treatment plan of small/medium bone defects in the oral cavity.

BAROREFLEX DYSFUNCTION IN CHRONIC KIDNEY DISEASE

Minela Aida Maranducă, Elena Cojocaru*, Ionela-Lăcrămioara Șerban

BAROREFLEX DYSFUNCTION IN CHRONIC KIDNEY DISEASE (Abstract): Chronic Kidney Disease (CKD) is a globally public health problem taking into account its direct role in morbidity and mortality. The essential risk factors that contribute to the development and progression of CKD are hypertension, diabetes and dislipidemy. Besides hypertension, variations in blood pressure caused by baroreflex control dysfunction can lead to chronic kidney disease progression. The causes of impaired baroreflex dysfunction control in chronic kidney disease are not fully known. Understanding the mechanisms that contribute to increased blood pressure variability due to baroreflex dysfunction in chronic kidney disease may represent a key element in diminishing the physio pathological processes that contribute to the development and progression of renal injury. **Keywords**: VARIABILITY, BAROREFLEX, CHRONIC KIDNEY DISEASE.

Chronic kidney disease involves a complex physio pathological process with multiple etiology, characterized by irreversible alteration in structure and function of the nephrons. Epidemiological studies have shown a prevalence constantly increasing worldwide, more pronounced in the last two decades. The cardiovascular disorders are complications related to chronic kidney disease, both diseases representing a public health problem with multiple social and economic implications. In early stages, chronic kidney disease still remains underdiagnosed and untreated. Early identification of chronic kidney disease, followed by the implementation of therapeutic strategies to prevent the occurrence of cardiovascular complications, would be the key elements in order to reduce morbidity and mortality, improving quality of life, to decrease economic costs and to increase survival rate of the patients.

Arterial hypertension – chronic kidney disease axis.

It is well known that the link between hypertension and renal dysfunction in chronic kidney disease is characterized by a highly association coefficient. Thus, elevated blood pressure can be found in over 90% of patients with renal impairment, which represents both cause and effect of chronic kidney disease. Clinical and experimental studies prove that renal hemodynamic changes resulting in increased glomerular capillary pressure contribute to progression of chronic kidney disease. The afferent arteriole vasodilatation results in an increase in glomerular filtration rate (GFR), renal plasma flow and also filtra-

tion fraction (1,2). An abnormal increase in systemic blood pressure transmitted to dilated afferent arteriole causes an increase in glomerular pressure. Glomerular hypertension and hyperfiltration are the main pathogenic mechanisms leading to glomerular injury (3). These hemodynamic changes are accompanied by enlargement of Bowman capsule, mesangial matrix proliferation and impairment of glomerular basement membrane integrity. Thus, an increase in systemic blood pressure transmitted to the glomerular apparatus plays an important role in the progression of chronic kidney disease.

Renal autoregulation.

Under normal conditions, transitory or sustained increases in blood pressure values are not transmitted to glomerular capillary due to autoregulation mechanism that causes preglomerular vessels constriction (4). For this reason, the glomerular filtration rate and renal plasma flow are constant in the presence of systemic blood pressure variations. Renal autoregulation remains a protective mechanism for glomerular diseases induced by increased blood pressure and also for maintaining normal excretory function (5). If renal autoregulation mechanism is impaired or if blood pressure values exceed the limits of autoregulation, renal microvasculature is exposed to increased pressure, which leads to renal injury. After reduction of functional renal mass or calcium blockers administration (6, 7, 8), there is a decline in kidney function autoregulation, even if systemic blood pressure remains within normal limits (9). Renal autoregulation is mediated by two interacting and synergistic control mechanisms: the intrinsic myogenic response of preglomerular vessels and tubulo-glomerular feedback mechanism. Myogenic mechanism involves direct vasoconstriction as reaction to increased local intravascular pressure. Tubulo-glomerular feedback mechanism is triggered when the concentration of sodium chloride in the distal convoluted tubule cells increases which stimulates the release of adenosine from *macula densa* cells. Adenosine initiates a cascade of events leading to afferent arteriole vasoconstriction in order to maintain a constant glomerular filtration rate (5). The stimulus which causes the activation of renal autoregulation is represented by modification of renal perfusion pressure.

Blood pressure variability.

Blood pressure variability as a mechanism of renal injury progression plays a central role in the physiopathology of this disease. The clinical and experimental studies have revealed that an increase in blood pressure variability causes organ damage (heart, brain, kidney), independent of its mean values (10). For instance, Ohasama study - a long-term prospective study regarding ambulatory monitoring of blood pressure - indicated that an increase in systemic blood pressure variability is an important indicator of cardiovascular mortality (11). A cause-effect relation between increased blood pressure variability and target organ damage is suggested by experimental studies showing that sino-aortic denervation increases blood pressure variability, without impairing mean values of arterial pressure (12, 13). In normotensive rats, sinoaortic denervation suppresses the changers induced by hypertension in heart, kidney and small arteries (14). A high variability in blood pressure is associated with frequent episodes of increased and decreased blood pressure values compared to mean arterial pressure. Frequent transitory elevations of blood pressure represent the

mechano-sensitive trigger of intracellular signalling mechanisms involved in target organ damage in hypertension (15). Besides that, even temporary reduction of blood pressure during episodes of hypo perfusion may have unfavourable effects on target organs.

Baroreflex system.

A short term control mechanism of blood pressure variability is the baroreflex system, whose main role is the short-term correction of blood pressure oscillations during everyday life. This system is composed of specialized mechano-sensory nerve endings known as baroreceptors, which are activated by vascular and/or heart distension during intraluminal blood pressure increasing. Arterial baroreceptors activity innervating the aortic arch and carotid sinus is increased or not according to blood pressure values. Thus, if arterial blood pressure is high, the activity of these receptors is significant and contrary it decreases if blood pressure values are low. Changes in arterial baroreceptor activity occur constantly, due to their efficiency and increased sensitivity, in order to a rapid correction of blood pressure variations, with a very low latency through an efficient negative feedback mechanism. Decreased baroreflex sensitivity occurs when the compensatory autonomic regulation is not appropriate (16). Epidemiological observations suggest that baroreflex dysfunction, manifested mainly by increasing of blood pressure variability associated to decreasing of heart rate variability, is correlated to a high risk of cardiovascular damage (17). Based on existing literature, we suggest that in chronic kidney disease there is a decrease in short-term control of blood pressure variability baroreflex-mediated.

Inflammation in chronic kidney disease: impact on autoregulation mechanism and baroreflex sensitivity.

Clinical studies show that chronic inflammation represents a risk factor for cardiovascular and renal pathology (18). Inflammatory biomarkers such as TNF-alpha (tumour necrosis factor-alpha), IL-6 (interleukin-6) and CRP (C-reactive protein) are predictive factors of mortality in patients with chronic kidney disease (19, 20, 21). Inflammatory cytokines (IL-6 and TNF-alpha) have both local and systemic action. IL-6 plays a major role in the immune response regulation in inflammation and has a very long serum half-life. Data obtained so far suggest that inflammatory cytokines are not only markers for the disease, but also its mediators (22). IL-6 promotes atherosclerosis and together with TNF-alpha induces structural changes in endothelial cells (23). The mechanisms by which inflammatory cytokines contribute to renal disease are not fully understood. At vascular level, cytokines induce the expression of some genes related to a number of autacoids (prostaglandins, leukotrienes, nitric oxide, reactive oxygen species and bradykinin), which affects vascular function. The vascular response depends on the balance between released autacoid type and degree of vascular damage. Minghini et al., have shown that exposure to IL-6 leads to vasodilatation of rat cremaster arterioles (24), and TNF-alpha determines arteriolodilatation during the exposure to endotoxin. If this effect occurs in the renal microvasculature, it can reduce myogenic response and the autoregulation capacity. Recent studies have suggested that circulating proinflammatory cytokines may have a direct effect on the central nervous system by stimulating the sympathetic nervous system flow (25). Consequently, elevated levels of TNF-alpha and IL-6 can deter-

mine an imbalance between autonomic baroreflex response stimulation and decrease of baroreflex sensitivity in chronic kidney disease. TNF-alpha and IL-6 promotes the development of atherosclerotic lesions in large vessels that could directly affect baroreceptor sensitivity to the pressure (26).

CONCLUSIONS

Summarizing the above data, we can conclude that understanding the mechanisms by which inflammation in chronic kidney disease triggers the baroreflex dysfunction can open new possibilities of therapeutic approach of this disease.

HYPERTHERMIC INTRAPERITONEAL CHEMOTHERAPY – A CUTTING EDGE THERAPHY FOR ADVANCED OVARIAN CANCER?

Nowadays, it is well known the importance of hypertermic intraperitoneal chemotherapy in colo-rectal cancer, pseudomyxoma peritoneii and malign mesothelioma, but it's significance in advanced ovarian cancer isn't so certain so far. There were published the results of a phase II study performed at the Unit of General, Emergency and Transplant Surgery at Sant'Orsola-Malpighi Hospital, University of Bologna, Italy, the Unit of General Surgery and Gynaecologic Surgery of Papa Giovanni XXIII Hospital, Bergamo and the Unit of Gynaecology of the Jena University Hospital, Germany. Patients with primary, advanced (FIGO stage IIIC to IV), or recurrent EOC were eligible for the present study to be treated with cytoreductive surgery and HIPEC with Cisplatin (100 mg/m^2) and Paclitaxel (175 mg/m^2). It seems that using cytoreductive surgery and HIPEC, using cisplatin and paclitxel it is feasible and comparable with the other drugs regimens with similar mortality and morbidity rate. The benefit for the overall survival and for the morbidity and mortality rate, it seems that it's a statement for the treatment in ovarian cancer (Federico Coccolini, Luca Campanati, Fausto Catena et al. Hyperthermic intraperitoneal chemotherapy with cisplatin and paclitaxel in advanced ovarian cancer: a multicenter prospective observational study. *J Gynecol Oncol*. 2016 Jan;26(1):54-61).

SURGICAL TREATMENT OF POSTPARTUM ILIOFEMORAL DEEP VEIN THROMBOSIS -CASE REPORTS (Abstract): The writing committee for Antithrombotic Therapy for Venous Thromboembolic Disease of the 2008 ACCP guidelines made the following recommendations for thrombus removal strategies in patients with deep vein thrombosis (DVT): open surgical thrombectomy is recommended in patients with acute iliofemoral DVT to reduce symptoms and post-thrombotic morbidity; whenever available, catheter-directed thrombolysis is preferred to surgical venous thrombectomy, the risk of hemorrhage being diminished; surgical venous thrombectomy is recognized to be efficient in cases where catheter-directed thrombolysis is unavailable or the patients are not suitable candidates for such a procedure. Randomized studies comparing surgical thrombectomy and anticoagulant therapy in patients with iliofemoral DVT (IFDVT) showed that at 6 months, 5 years, and 10 years the patients in the thrombectomy group presented increased permeability, lower venous pressure, less edema, and fewer postthrombotic symptoms compared to the patients receiving anticoagulant therapy. In this article we present 3 cases of IFDVT in postpartum patients diagnosed by Doppler ultrasound of the deep venous system. The 3 patients received anticoagulant therapy prior to surgery. Surgery consisted in thrombectomy of the common, superficial and deep femoral veins, external and internal iliac veins, and femoral-saphenous arteriovenous fistula. The patients received postoperative antithrombotic therapy and were followed-up at 3,6 and 9 months by Doppler ultrasound of the deep venous system. **Keywords:** DEEP VEIN THROMBOSIS, DOPPLER ULTRSOUND, VENOUS THROMBECTOMY, ARTERIOVENOUS FISTULA, ANTICOAGULATION, POSTPARTUM.

Deep vein thrombosis (DVT) is clotting of blood in the deep venous system of the limbs to which a venous wall inflammatory response can be associated. The factors that predispose to venous thrombosis are the ones described by Virchow in 1856 and include venous stasis, vein wall injury, and hypercoagulability(1).The writing committee for Antithrombotic Therapy for Venous Thromboembolic Disease of the 2008 ACCP guidelines made the following recommendations for thrombus removal strategies in patients with DVT: open surgical thrombectomy is recommended in patients with acute iliofemoral DVT to reduce symptoms and post-thrombotic morbidity; whenever available, catheter-directed thrombolysis is preferred to surgical venous thrombectomy, the risk of hemorrhage being diminished; surgical venous thrombectomy is recognized

to be efficient in cases where catheter-directed thrombolysis is unavailable or the patients are not suitable candidates for such a procedure(2,3).The patients who underwent venous thrombectomy had greater permeability, lower venous pressure, less edema, and fewer postthrombotic symptoms compared to the patients treated with anticoagulants alone (4).

CASE REPORTS

We present 3 cases of DVT in postpartum patients.

Case 1.

A 28-year-old female with onset of DVT 12 postpartum. The patient was transferred from the Obstetrics Clinic to the Vascular Surgery Clinic where anticoagulant therapy with heparin 25,000/24h was initiated and then continued with oral anticoagulation with Sintrom 4mg/day, on admission the patient having an INR of 2.3.With this treatment the patient showed a slow improvement of symptoms. Doppler ultrasound of the deep venous system on admission showed cardiac and respiratory modulation of inferior vena cava blood flow, left iliofemoral-popliteal thrombosis, thrombosis at the arch of the internal saphenous vein (VSI) with collateral flow 11 cm from the valve, the remaining VSI being depressible. The patient continued to receive anticoagulant therapy with heparin 1000 UI/24h until surgery. Surgery consisted in thrombectomy of the common femoral vein (VFC), common iliac vein (VIC), external iliac vein (VIE), and a femoral-saphenous arterio-venous fistula (fig. 1, 2).

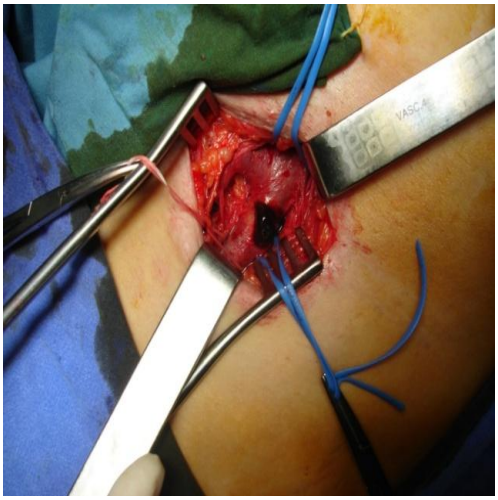

Fig. 1. VFC trombus

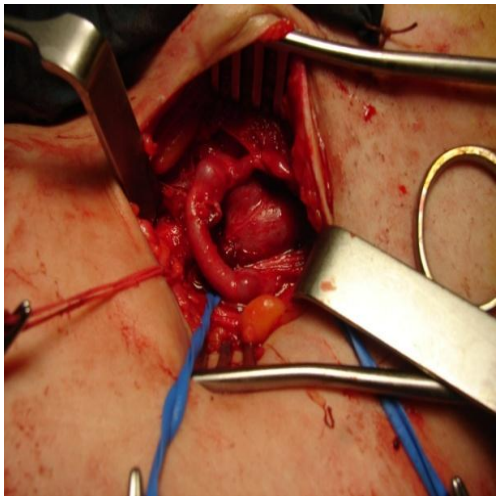

Fig. 2. Femoral-saphenous arteriovenous fistula

The immediate surgical outcome was favorable. Heparin therapy was continued for 7 days postoperatively followed by low molecular weight heparin for 4 days associated in the last 2 days with Sintrom, an INR of 2-3 being obtained. The anticoagulant therapy was associated with the elevation of the lower leg and elastic compression (18-21 mmHg). The long term follow-up (at 3, 6 and 9 months) showed favorable results with the remission of symptoms and permeable deep venous system demonstrat-

ed by deep vein ultrasound.

Case 2.

A 36-year-old female with DVT detected at 24h postpartum. The patient presented severe, continuous pain in the left thigh and calf, more intense during mobilization, significant edema of the left thigh and calf, positive Homans sign, imperceptible left anterior and posterior tibial artery pulse due to the edema but positive Doppler signal at the same level. Doppler ultrasound showed thrombosis of the common, superficial and deep femoral veins, external iliac vein, and partial thrombosis of the common iliac vein with blood flow in the inferior vena cava. Preoperatively, anticoagulant therapy with heparin 1000 UI/hwas administered via syringe pump. Surgery consisted in iliofemoral venous thrombectomy and left femoral-saphenous arterio-venous fistula. The postoperative outcome was unfavorable with recurrent common femoral vein thrombosis. Reoperation consisted in femoro-popliteal venous thrombectomy and left popliteo-popliteal fistula, with favorable surgical outcome. The follow-up Doppler ultrasound at 3, 6, and 9 months showed permeability of the iliac veins, common and deep femoral veins, popliteal vein, and recurrent thrombosis in the superficial femoral vein. Postoperatively the patient continued the anticoagulation therapy with Sintrom 4 mg per day, with the INR maintained at 2.5-3.5.

Case 3.

A 31-year-old woman who developed DVT detected by Doppler ultrasound 7 days postpartum. Anticoagulant therapy with heparin 1000 UI/h via syringe pump was initiated preoperatively. Surgery consisted in ilio-femoral venous thrombectomy aimed at recanalization of the right popliteal vein and femoro-femoral arteriovenous fistula. The immediate surgical outcome was favorable, ultrasound showing a permeable ilio-femoral venous axis. The patient continued the anticoagulation therapy postoperatively. The long term follow-up at 3, 6, and 9 months showed the recurrence of thrombosis in the superficial femoral vein but with permeable right iliac and popliteal veins.

DISCUSSION

In patients with ilio-femoral deep vein thrombosis Rutherford recommends the use of the techniques designed for thrombus removal: open surgery, thrombolysis or endovascular techniques, because of the increased risk of pulmonary embolism and post thrombotic syndrome due to the impaired valvular function (1).

Plate G. et al. demonstrated in 3 studies that patients who underwent venous thrombectomy show improvement in iliac vein permeability, reduced venous pressure, reduction of edema, fewer symptoms due to post thrombotic syndrome than patients who received oral anticoagulation alone. Also, in these patients the valvular function of the femoral-popliteal venous segment is preserved compared to those treated with anticoagulants (4, 10). This was also found by Killewichet al (5).

Rutherford suggests that before choosing the thrombus removal procedure, the risk of pulmonary embolism associated with that procedure has to be taken into account. Patients with free-*floating thrombus* in the inferior vena cave are at the highest risk of developing pulmonary embolism. Therefore, it is necessary to know the upper and lower limit of thrombosis and most particularly the level of involvement of the inferior vena cava (1,6,7).

The writing committee for Antithrom-

botic Therapy for Venous Thromboembolic Disease of the 2008 ACCP guidelines made the following recommendations for thrombus removal strategies in patients with DVT: open surgical thrombectomy has to be performed in patients who are not candidates for catheter-directed thrombolysis (high bleeding risk) or reside in communities where this method is not available.

CONCLUSIONS

Since catheter-directed thrombolysis is not available in our clinic we opted for surgical venous thrombectomy. During this procedure an arterio-venous fistula should be created to help maintain blood flow in the deep venous system, without it the rethrombosis rate being very high (8,9,10). Surgery has to be preferably performed within the first 14 days but not later than 3 weeks. Any aggressive method of thrombus removal or lysis is better than no interventional treatment. Even though some authors are strong supporters of anticoagulant therapy, interventional strategies (endovascular or surgical) allow early mobilization as soon as possible, thus meeting the wishes of some patients, particularly younger patients.

Postoperatively, the patients received anticoagulation therapy with vitamin K antagonists, INR being maintained between 2.0 and 3.0.

In all these 3 cases, the symptoms remitted with preservation of permeability of the iliac vein, deep common femoral vein and popliteal vein, rethrombosis in the superficial femoral vein occurring in 2 cases.

INTRAUTERINE GROWTH RESTRICTION – PREDICTIVE SERUM MARKERS (Abstract) **Aim:** To determine during the first trimester of pregnancy some serum and ultrasound markers that could improve perinatal morbidity and mortality in women with intrauterine growth restriction (IUGR). **Material and methods:** Prospective study of pregnant women gestational age 11 weeks and 0 days - 13 weeks and 6 days, consisting in the determination of pregnancy associated plasma protein (PAPP-A), mean platelet volume (MPV), and ultrasound appearance of placenta. **Discussion and Conclusions**: This study suggests that screening by detailed history and PAPP-A and MPV determination during the first trimester of pregnancy in women at risk for IUGR makes possible the prophylactic treatment and monitoring of pregnancy according to a given protocol and thus neonatal morbidity and mortality to be reduced. **Keywords:** INTRAUTERINE GROWTH RESTRICTION, PREGNANCY-ASSOCIATED PLASMA PROTEIN, MEAN PLATELET VOLUME.

Detection of IUGR risk in pregnant women in the first trimester is an important goal of research in modern obstetrics. It is known that fetuses diagnosed with IUGR are at high risk of perinatal morbidity and mortality by the complications that may occur (1,2,3).

In this context the early determination of the predictive markers for the risk of IUGR is essential. First trimester screening consists in the monitoring of pregnant women at risk according to a secondary prevention protocol and monitoring specific to each associated disorder so that the following two situations that affect fetal prognosis to be avoided:

- ✓ premature, unnecessary extraction of a healthy fetus
- ✓ delayed extraction due to fetal distress undetected on time and which can result in intrauterine fetal death

Evaluation of the predisposing/causative factors for IUGR is the first step and consists in history taking, thorough physical examination, ultrasound, and specific laboratory tests, all aimed at ultimately determining the presence or absence of the risk for IUGR (4-16)

PAPP-A is a protein secreted by the syncytiotrophoblast cells and maternal decidua, thus low PAPP-A levels are associated with abnormal placentation and fetal growth (17-22).

MPV – Increased MPV reflects en-

hanced platelet activation, which may be caused by impaired uteroplacental circulation, and inadequate trophoblastic invasion, associated with an implicit risk of preeclampsia (PE) and IUGR (23-25)

MATERIAL AND METHODS

This prospective study was conducted in 70 women 11 weeks and 0 days -13 weeks and 6 days gestational age monitoring their pregnancy at the Neamt County Emergency Hospital between August 1, 2014 and September 1, 2015.

Throughout their pregnancy the women included in the study received prenatal care:

- ultrasound examinations (at 12 -13 weeks - fetal morphology, fetal development and placental appearance, at 22-24 weeks – fetal morphology, uterine artery Doppler study, at 32-34 weeks – fetal well-being study), repeated depending on fetal status and pregnancy-related disease;

- laboratory tests according to the protocol: complete blood count, MPV, blood glucose level, urea, creatinine, uric acid, transaminases, anti-toxoplasma antibodies (Ab), rubella Ab, anti-herpes Ab, cytomegalovirus (CMV), urinalysis, repeated depending on pregnancy-related disease.
- double test as part of biochemical screening (PAPP-A and beta-human chorionic gonadotropin (B-HCG) hormone.

The study aimed to determine the PAPP-A, MPV and ultrasound placental changes, as potential predictors of the risk for IUGR.

Each participant signed and informed consent form approved by the ethics committee.

Inclusion criteria for participation in the study were:

– 11 weeks and 0 days -13 weeks and 6 days pregnant women at a craniocaudal length (LCC): 44,5 mm – 84.5 mm)

– Normal fetal morphology

Exclusion criteria:

– Double tests with high risk for trisomy 13, 18, 21

– Fetal abnormalities diagnosed with ultrasound in the first trimester

– Genetic abnormalities confirmed by chromosomal analysis of cells obtained by chorionic villus biopsy.

– Pregnancy achieved through in vitro fertilization (IVF)

– Twin pregnancy.

PAPP-A was determined as part of first-trimester biochemical screening for aneuploidy at a LCC of 44,5 mm – 84,5 mm. Samples were processed with Brahms Kryptor immunoassay analyzer. The results were expressed as multiples of median (MoM).

The data were imported into, processed and analyzed using the SPSS version 18.0, and were statistically significant at 95% confidence level. Chi-square test was used to determine statistical significance. Frequencies and mean values for the quantitative and qualitative determinations were calculated and Pearson and Fearman tests were used to find the correlations between several variables. The difference was considered statistically significant at $p < 0.05$.

RESULTS

This study was conducted in a group of 70 pregnant women monitored at the Neamt County Hospital in the interval August 1, 2014 - September 1, 2015. Pregnancies were dated by LCC at first ultrasound, LCC ranging from 44.5mm to 84.5mm.

Physical examination and history identified the following pregnancy-associated disorders and predisposing factors of IUGR: thrombophilia in 8 cases, uterine fibroma 1 case, pre-existing thrombocytopenia 1 case, iron deficiency anemia 7 cases, preexisting hypertension 11 cases, type 1 diabetes 7

cases, and smoking in 11 cases.

The 70 pregnant women included in this study gave birth to 41 small-for-gestational age pregnancy (SGA) and 29 normal weight babies (fig. 1). Of the 41 cases with IUGR, 30 had a first trimester PAPP-A <0.5 MoM, confirming the statistically significant correlation between maternal PAPP-A level and birth weight (p=0.016).

At the baseline ultrasound performed at 12-13 weeks gestation the ultrasound appearance of placenta was also assessed (presence of deciduous hematoma, areas of angiomatous transformation, detachment of placenta), which suggests impaired first wave of trophoblast invasion and thus a possible long-term placental insufficiency and implicitly risk of IUGR. In 25 cases such changes were identified.

Thirty of the infants had low birth weight and first trimester MPV levels > 10 fl, (fig. 2). A statistically significant correlation was found between birth weight and first trimester MPV level (p = 0.001).

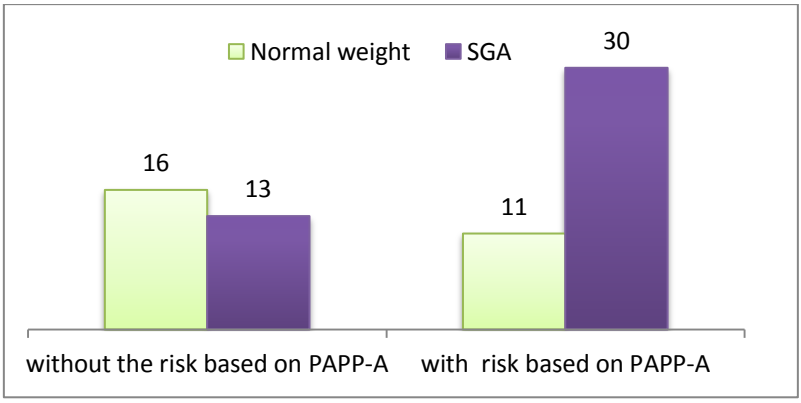

Fig. 1. Distribution of cases by birth weight and PAPP-A

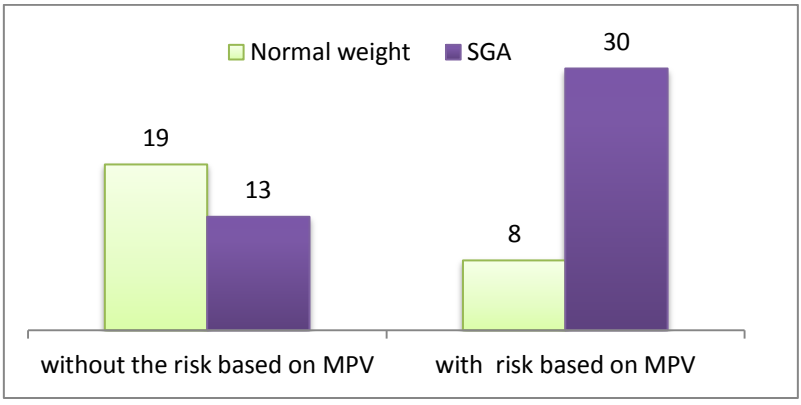

Fig. 2. Distribution of cases by birth weight and MPV

DISCUSSIONS

IUGR is a current problem and a research topic in modern obstetrics. In practice, IUGR has a statistical definition and is a fetal weight or fetal biometry below the 10th percentile or 2 SD below the mean for

gestational age (3, 4). According to the data in the literature, elevated PAPP-A levels are not correlated with increased risk of obstetric pathology, but it was found that a PAPP-A level below the 5th percentile is associated with increased risk of IUGR (17-22).

A study by M. Kwik in 894 women in the first trimester of pregnancy showed that serum PAPP-A levels <0.5 MoM have a sensitivity of 33% and a specificity of 89% in detecting fetuses with a weight below the 10th percentile. Low PAPP-A levels indirectly indicate abnormal placentation, that is a placental insufficiency which has effects on fetal growth (19).

In our study 30 of the pregnant women with IUGR had PAPP-A levels <0.5 MoM, suggesting a statistically significant correlation between IUGR and PAPP-A (p = 0.016).

Increased MPV reflects platelet activation caused by uteroplacental circulatory insufficiency, pathophysiological mechanism with repercussions on fetal growth. In this study it was found that 30 newborns had low birth weight and a first trimester MPV level > 10 fl, p = 0.001, data consistent with the literature (23-25).

A study by M. Kanakt-Pektas shows that MPV levels > 10 fl can predict IUGR with a sensitivity of 82.4% and specificity of 60% (24).

In our study, 41 pregnant women had PAPP-P levels <0.5 MoM and in 38 cases MPV level was > 10fl, which, according to the above mentioned literature data, can be used as markers for the early prediction of IUGR.

The ultrasound appearance of impaired first wave of trophoblast invasion is described as intra-and/or periplacental pathological areas which can be considered a possible cause of placental insufficiency, thus a risk of IUGR.

CONCLUSIONS

This study shows that the early detection of serum markers PAPP-A, MPV and placental changes detected at ultrasound and the detailed medical history obtained during the first trimester of pregnancy can be used as screening markers for the detection of cases at risk for IUGR. Identifying pregnancies at risk for IUGR during the first trimester requires the use of secondary preventive measures and monitoring of these cases in order to reduce neonatal morbidity and mortality.

CEPHALOMETRIC FEATURES OF CLASS III MALOCCLUSION (Abstract): **Aim**: The study aimed to identify quantitative and relational characteristics of bone, dental and soft tissue structures for Class III malocclusion, according to gender and age range. **Material and methods**: 60 conventional lateral cephalograms were divided into two groups according to ANB angle: the group of cases with skeletal Class III (n=36) and a control group with skeletal Class I (n=24). There were performed 53 digital cephalometric measurements according to Steiner, Tweed and Jarabak analyzes. The Kolmogorov-Smirnov, t-student and Levene tests were used to find the characteristics of Class III, using SPSS 16.0 for Windows. **Results**: We found 14 parameters that distinguished the two classes disorders (the angles SNB, SND, FMA, IMPA, MeGoOcP, Mand 1-MeGo, NSAr, ArGoMe, NGoMe and SNPog; the distances Ao-Bo and 1u-NPog; Holdaway and AFH ratios) and 3 parameters for the Class III age ranges (NGoAr angle, Ls-NsPog' distance and S-Ar:Ar-Go ratio) ($p \leq 0.05$). There were found no significant differences between genders for skeletal Class III. **Conclusion**: Emphasizing the cephalometric characteristics of Class III malocclusion, with the overall growth together with dental and occlusion development, requires early orthodontic therapy. **Keywords**: CONVENTIONAL LATERAL CEPHALOMETRIC RADIOGRAPHY, CLASS III MALOCCLUSION, DIGITAL CEPHALOMETRIC MEASUREMENTS.

Class III malocclusion is characterized by a mesial relation of the mandible compared to the maxillary, the cause beeing skeletal and its origin is usually hereditary (1). This anomaly shows a low prevalence at the white population (1-2%) and with an increased frequency in Asian countries like Japan (4-13%) (2).

Bourdet (cit by 3) was the first researcher who described the 1737 skeletal Class III pattern in children with mandibular prognathia. In such cases, lateral cephalometric radiography is essential in establishing the skeletal, dental and facial diagnosis in order to appropriately apply orthodontic or surgical treatment (4). Sagittal discrepancies are mainly due to excessive growth of the mandible with hyperdivergence growth pattern, resulting mandibular prognathia. Most studies of skeletal Class III malocclusion were performed on Eastern Asian populations (5-9). Diversity of opinion on parameters values of cephalometric characteristics of skeletal Class III are supposed to be the expression of the ethnic composition of the groups studied (10-12).

Our research was conducted in order to investigate the cephalometric characteristics of skeletal Class III malocclusion on a sample of patients without orthodontic treatment from the northeastern region of Romania. The aim of the study was to compare the cephalometric parameters of Class III with the skeletal Class I, to identify quantitative and relational differences of bone, dental and soft tissues structures, by gender and age range.

MATERIAL AND METHODS

This retrospective and case-control study was conducted for 60 conventional lateral cephalograms, from the Orthodontics Clinic at the Ambulatory Clinic of the "St. Spiridon" University Emergency Hospital, Iasi, Romania, during January 2006 and December 2014. The cephalograms' selection criterion was their good technical quality. All radiographs were performed with the same X-ray device, the STRATO-X Orthopantomograph with magnification factor of 11.8%.

The lateral cephalograms provided from patients from northeastern Romania, (28 - 47% males and 32 - 53% females), with ages between 7–26 years (mean 14.33±5.758 years), without previous orthodontic treatment. The patients cephalograms were divided in two groups, by skeletal class (ANB angle): cases group=36 (60%) patients with skeletal class III (ANB<2°), which were 17 (42%) males and 19 (53%) females, 26 (72%) with age <14 years and 10 (28%) with age >14 years; control group=24 (40%) patients with skeletal class I (ANB≤4°), witch are 11 (46%) males and 13 (54%) females. The patients with craniofacial dysostosis, craniofacial synostosis, endocrine and genetic syndromes were excluded. The informed consent was acquired from all subjects or the patients' parents. The study was conducted in accordance with the Helsinki Declaration of 1975, as revised in 2000.

The anatomical outlines of the lateral cephalograms were drafted on tracing paper with a 0.5mm diameter pencil. The tracing paper was scanned (MFD Canon Pixma MP280) in digital format (JPG File), after which it was stored on a computer (Asus Eee PC 1015BX) (13). The digital cephalometric analysis was performed with Onyx Ceph™ (Onyx CEPH 2.7.18 (174) Image Instruments GmbH, Chemnitz, Germany). The landmarks were located with the mouse pointer directly on the digital paper image on the computer display (fig. 1).

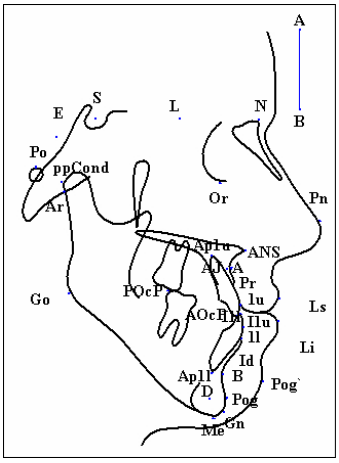

Fig. 1. Cephalometric landmarks: sella (S), nasion (N), E-point (E), L-point (L), porion (Po), condylion posterior (ppCond), articulare (Ar), orbitale (Or), gonion (Go), menton (Me), gnathion (Gn), pogonion (Pog), D-point (D), anterior nasal spine (ANS), A-point (A), A-point acc. to Jarabak (AJ), prosthion (Pr), infradentale (Id), B-point (B), upper incisor apex (Ap1u), upper incisor crown tip (1u), incision superior (I1u), incision inferior (I1l), lower incisor crown tip (1l), lower incisor apex (Ap1l), anterior point for the occlusal plane (AOcP), posterior point for the occlusal plane (POcP), pronasale (Pn), labrale superior (Ls), labrale inferior (Li) and pogonion soft tissue (Pog')

For each imagines there were measured 28 angles (°), 21 linear dimensions (mm) and 4 bone ratios (%), dental and soft tissues (n=53 measurements), using Steiner (14), Tweed (15) and Jarabak (16) analyses (fig. 2). Every single scanned paper was digitally measured under identical calibration conditions for the size of the cephalometric images. All data obtained were extracted and stored in the electronic format (Microsoft Office Excel 97-2003 Worksheet). The protocol included a quantitative evaluation of the skull basis, maxillary, mandible, and the relations between them, as well as with the dental and soft tissues.

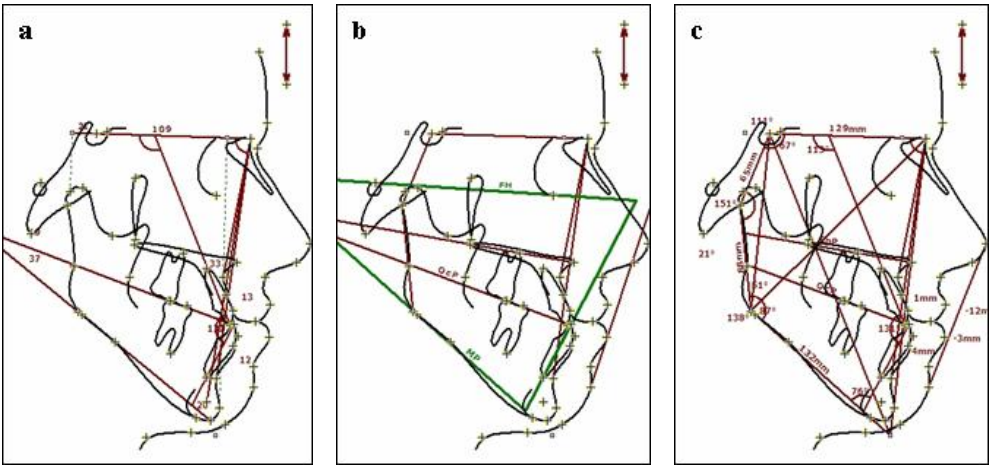

Fig. 2. Cephalometric parameters

(a) acc. Steiner: SNA, SNB, ANB, SND, II, SN-OcP, SN-GoGn, Max1-NA, Max1-SN, Mand1-NB, 1u-NA, 1l-NB, Pog-NB, Holdaway ratio, S-L and S-E. (b) acc. Tweed: FMIA, FMA, IMPA, Wits, PoOr-OcP, Z, PFH, AFH and AFH:PFH. (c) acc. Jarabak: MeGo-OcP, Mand1-MeGo, 1u-NPog, 1l-NPog, Ls-PnPog', Li-PnPog', NSAr, SArGo, ArGoMe, Sum, N-S, S-Ar, NGoAr, NGoMe, Ar-Go, S-Ar:Ar-Go, Go-Me, SN-GoMe, GoMe:NS, N-Go, S-Me, NSGn, S-Go, N-Me, SGo:NMe, SNPog and NAPog.

Statistical analysis was made with program SPSS 16.0 (SPSS Inc., Chicago, IL), for Windows. The numerical values were calculated according to the parameters of descriptive statistics (mean value, standard deviation (SD), error of standard deviation (SEM), minimum and maximum value). To compare the measured values of the two skeletal classes, sexes and age intervals, the Kolmogorov-Smirnov, t-Student and Levene tests for the equality of variances were applied, with $p \leq 0.05$ value, corresponding to the 95% confidence interval, beeing considered statistically significant.

RESULTS

There were measured the angles and distances between the bone structures, dental and soft tissues for each lateral cephalometric radiograph, using the three cephalometric analyses. The measurement mean values were compared between the two skeletal classes.

For the Steiner (14) analysis there were found statistically significant differences between skeletal classes for the sagittal position of the mandible to the anterior cranial base plane (SNB angle), sagittal position of symphysis mentalis to the ante-

rior plane of the cranial base (SND angle) and for Holdaway ratio (tab. I).

For the Tweed (15) analysis there were found statistically significant differences between skeletal classes for the mandibles' growth direction (FMA angle), sagittal position of the lower central incisor to the mandibular plane (IMPA angle), sagittal relation of maxillary-mandible (Wits or distance Ao-Bo) and for skeletal anterior height (AFH) (tab. II).

For the Jarabak (16) analysis there were found statistically significant differences between skeletal classes for inclination of the occlusal plane to mandibular basis (MeGoOcP angle), sagittal position of the lower central incisor to mandibular basis (Mand 1-MeGo angle), sagittal position of the upper central incisor to the Downs facial plane (distance 1u-NPog), temporo-mandibular joint and glenoid Fossae position (NSAr angle), type of condylar growth (ArGoMe angle), type of mandibular growth (NGoMe angle) and sagittal position of mandibular basis to the anterior cranial base plane (SNPog angle) (tab. III).

Other differences of angular, linear and ratios measured mean values were not significant.

The mean values of the digital measurements of skeletal Class III were compared between the two sexes and no statistically significant differences were found.

The mean values of the digital measurements of skeletal Class III were compared for two intervals of age <14 years and >14 years and there were found statistically significant differences for the type of mandibular growth (NGoAr), sagittal position of the upper lip (Ls-NsPog') and for the cranial base length and mandibular ramus height ratio (S-Ar:Ar-Go) (tab IV).

DISCUSSION

Our research has focused on the comparison of cephalometric measurements between skeletal Class III and Class I in order to identify the quantitative characteristics and bone structures relations, dental and soft tissues of Class III malocclusion, according to gender and age range. The skeletal Class was identified using the ANB angle value, beeing recognized by many authors as the skeletal discrepancies indicator (11, 13, 17, 18). We used three cephalometric analyzes used by orthodontists, in order to identify three aspects (skeletal, dental and soft tissues) characteristic to the Class III malocclusion. We chose efficient cephalometric analysis software for precision measurements.

Using statistical tests allowed us to find significant differences between skeletal Classes, which represented the defining parameters of skeletal Class III malocclusion for the studied population. Thus, we found 14 statistically significant measure-

ments (10 angular, 2 linear and 2 of percentage), that characterized the skeletal Class III: mandibular prognatia by the anterior sagittal position of the mandible to the anterior cranial base plane (increased SNB angle and decreased Ao-Bo distance); progeny by the anterior sagittal position of symphysis mentalis to the anterior cranial base plane (increased SND and SNPog angles and Holdaway ratio); mandible's hyperdivergent growth (increased FMA and NgoMe angles); lower dental retroclination (decreased IMPA and Mand 1-MeGo angles and 1u-Npog distance); occlusal plane tilting towards the mandible basis (increased Me GoOcP angle); anterior position of temporomandibular joint (decreased NSAr angle); posterior condylar growth, with the opening of the mandibular angle (increased ArGoMe angle); facial anterior height growth (increased AFH ratio).

Previous comparative studies (of Class I and Class III) reported similar parameters as prognathia, posterior mandibular rotation, forward position of the mandible and lower central incisor retroclination (3, 6-9, 19-22), as well as different parameters as cranial base shortening, underdeveloped maxillary, upper central incisor proclination and facial deficiency of the zygomatic region (11, 12, 23, 24). Results are still controversial and some authors argue that the cranial morphology in subjects with Class III does not differ from those with Class I (8, 25). Contradictions in existing trials results are due to the heterogeneity of ethnic, race and age diversity of studied groups and research methods.

In our study, the digital measurement values of skeletal Class III were compared between sexes and we did not find statistically significant differences. The literature reports significant differences between the sexes regarding the position of the upper lip (26).

In the present study, statistically significant differences between the two age ranges, prepubertal (<14 years) and pubertal-postpubertar (>14 years) of skeletal Class III, showed emphasis of several characteristics together with the growth dental-maxillofacial complex, at the studied population. Thus, we found 3 parameters that showed the emphasis of the vertical growth of the mandible (decreased NGoAr angle), mandible prognathia (decreased S-Ar:Ar-Go ratio) retrusion of the upper lip (decreased Ls-NsPog' distance). Previous studies show that specific Class III parameters are established from an early age and are maintained throughout the skeletal growth (6, 27), and puberty is of significant importance on the mandibular length growth, the maximum pubertal beeing extended in subjects with class III (10, 28).

Our study presents anthropometric importance in the population studied and has clinical-diagnostic value for a correct specialized orthodontic or surgical therapy (4).

CONCLUSIONS

The present study demonstrates that the Class III malocclusion shows a distinct pathology, characterized by a series of specific cephalometric parameters which set the diagnosis and indicate the morphological dental-maxillofacial segment that should be orthodontically corrected as early as possible.

Our study has particular importance for practitioners and suggests the necessity in their involvement in identifying at an early age these serious skeletal discrepancies. Future similar studies may extend to other types of skeletal malocclusion affecting facial esthetics and dental health of our young population.

HISTOPATHOLOGICAL VARIANTS IN RENAL TUMORS: FROM COMMON TO UNCOMMON SUBTYPES (Abstract): **Aim**: The assessment of renal tumors diagnosed in a department specialized in kidney pathology, following the correspondence between the identified histological subtypes and pathological background reported in the literature. **Material and Methods:** The study group included 219 patients diagnosed with renal tumors and surgically treated in the University Hospital "Dr. C.I. Parhon", Iaşi. Histopathological diagnosis was revalued reconsidering microscopic specimens consequent to analyzed cases. **Results:** In 204 (94.4%) of the 219 cases there were no differences between initial diagnosis and the diagnosis subsequent to revaluation. After microscopic examination, most cases were classified as clear cell renal cell carcinomas and urothelial carcinomas. For clear cell renal cell carcinoma and urothelial carcinomas we registered different percentages compared with data reported in literature (86.27% *vs.* 70-75%, 28.81% *vs.* 10% respectively). **Conclusions:** Our results point out the possibility of identifying epidemiological features with regional / national specificity. **Keywords**: RENAL TUMOR, HISTOLOGICAL SUBTYPE, CLEAR CELL RENAL CELL CARCINOMA.

The pathologist applies as a diagnostic operational tool the WHO histological classification of renal tumors which includes nine major classes: renal cell tumors, metanephric tumors, nephroblastic tumors, mesenchymal tumors, epithelial and mesenchymal mixed tumors, neuroendocrine tumors, hematopoietic and lymphoid tumors, germ cell tumors, and metastatic tumors (1). Additionally, should be considered the urothelial tumors category with renal pelvic origin, representing approximately 10% of renal tumors (1).

Renal cell carcinoma (RCC) represents approximately 3% of all human malignancies (2, 3) and approximately 90% of all kidney tumors. Analysis of incidence and mortality assigned to RCC shows a noticeable regional variability, which is probable the result of demographic, environment, and genetic factors influence. The efforts to identify the reversible factors that cause renal carcinoma development, have led not only to a better understanding of its etiology, but also of the genetic features associated to histological profile (4). RCC prognosis

is generally related with the tumor stage being proved that the survival of stage I is> 90% at 5 years, while of stage IV is <20-30%. Unfortunately, renal tumors often remain asymptomatic until advanced stages. Due to its origin in various tubular structures of the kidney parenchyma, RCC is characterized by a marked heterogeneity, being described many morphological subtypes (5). Clear cell RCC accounts for approximately 70-75% of cases, followed by papillary RCC (10-15%), chromophobe RCC (5%), collecting duct RCC (<1%) and unclassified form (<2%) (5-7). Sarcomatoid features can occur in all forms of RCC, as a sign of active epithelial-mesenchymal transition (5, 8).

Other rare histological types are: medullary RCC, translocation RCC, and mucinous tubular and spindle-cell RCC (5, 9). In the last years, new epithelial tumor subtypes were described: tubulocystic RCC, acquired cystic disease-associated RCC, clear cell tubulopapillary RCC, the microphthalmia (MiT) family translocation RCCs, and hereditary leiomyomatosis-RCC syndrome-associated tumors (5, 10), and 3 new entities with a provisional status were proposed: thyroid-like follicular RCC, succinate dehydrogenase B deficiency-associated RCC; and anaplastic lymphoma kinase translocation RCC (5, 10).

Our study aimed to analyze the renal tumors diagnosed in a department specialized in kidney pathology, following correspondence between identified histological subtypes and pathological background reported in the literature.

MATERIAL AND METHODS

The study group included a total of 219 patients diagnosed with renal tumors surgically treated in the Urology Department, University Hospital "Dr. C.I. Parhon", Iaşi during 2010-2013. The male patients accounted for 123 cases (55%) while female patients accounted for 101 cases (45%). The age interval ranged between 20 and 84 years (mean 62.98 years). Tissue samples from surgical procedures were processed in the Laboratory of Pathology using standard protocol in order to obtain microscopic preparations for histopathological diagnosis. A retrospective, descriptive study was initially performed, based on the existing pathology reports. Subsequent, all microscopic slides corresponding to the analyzed cases were cross-assessed by three pathologists, in order to review the diagnosis.

RESULTS

All cases were histopathologically classified according to the WHO histological classification of renal tumors (tab. I). For 204 (94.4%) of the 219 analyzed cases there were no differences between initial diagnosis and the diagnosis after re-evaluation. A total of 12 cases, 11 diagnosed as mixed renal cell carcinoma and 1 case diagnosed as renal cell carcinoma with high-grade anaplasia were assigned as clear cell renal cell carcinoma.

TABLE I

Distribution of histological subtypes

Histological subtype	Number of cases	Percentage
Cell clear renal carcinoma	132	60.27%
Urothelial carcinoma	63	28.81%
Oncocitoma	12	5.47%
Papillary renal cell carcinoma	9	4.10%
Angiomyolipoma	1	0.45%
Angiomyofibroma	1	0.45%
Metastatic digestive tumor	1	0.45%

The microscopic exam in cases classified as clear cell renal cell carcinoma (ccRCC) highlighted various aspects. Some cases

presented cystic and solid areas with infiltration limited to medulla or with cortex, capsule or perirenal adipose tissue invasion. Other cases of ccRCC showed large areas of sarcomatous transformation. We identified also ccRCC with multinodular appearance, with high index of nuclear atypia and large areas of necrosis and hemorrhage. In most cases, the large vessels hilum had no tumor emboli. In the 11 cases (5.02%) initially considered as mixed renal cell carcinoma, based on the association between clear cell renal cell carcinoma areas and large areas of tumoral cells with cytoplasm predominantly acidophile, or isolated chromophobe, with tubulo-papillary or papillary pattern, the histologic revaluation resulted in their classification as clear cell renal cell carcinoma, motivated by the certain presence of tumor cells with typical appearance of clear cell, even if in limited territories. The same diagnostic criterion was applied to 1 case initially diagnosed as renal cell carcinoma highly anaplastic.

In case of oncocytomas, *the microscopic exam* revealed the presence of round or polygonal cells arranged in nests or with alveolar or tubular pattern and rare microchystic areas, with abundant, intensely eosinophilic, and finely granular cytoplasm, and small, round, centrally located nuclei, with uniform chromatin and finely contoured nuclear membrane. The myxoid or hyalinized stroma included oncoblasts - small cell with minimum cytoplasm and small, hyperchromatic nuclei.

The microscopic structure of angiomyolipoma revealed myoide fusiform cells, areas of mature adipose tissue and dysmorphic thick walled blood vessels without elastic lamina. Areas represented by smooth muscle component showed hypercellular, atypical, pleomorphic or epithelioid appearance. We identified also necrosis and hemorrhage areas associated with stromal sclerosis. In the structure of angyomiofibroma we noted high cellular density and nuclear pleomorphism particularly in the myomatous areas.

In one case, the diagnosis was metastatic tumor. *The immunohistochemical profile* of undifferentiated tumor cells, with glandular and compact architecture, confirmed the digestive origin of the primary tumor.

The microscopic exam in urothelial carcinoma with renal pelvic origin showed papillary pattern, G2 or G3 degrees of differentiation, infiltrating adjacent renal parenchyma, with large areas of necrosis, commonly tumor emboli in lymphovascular spaces and perineural invasion in the hilum.

DISCUSSION

The classification of renal tumors registered significant changes in recent decades, due to progress in deciphering the molecular profile of this pathology (5, 9, 10). Genomic analysis demonstrated that the differences between tumor subtypes are not based only on histological criteria, but also on the specific genetic mutations (5, 11). Consequently, enhanced awareness of biological and genomic characteristics of different tumor subtypes enabled the development of targeted therapies (12). There are two aspects to be highlighted. First, although genetic alterations are important, 96% of all cases are sporadic forms of RCC and only 4% are hereditary (13, 14). Secondly, the predominant histological subtypes in the pathology of renal tumor are clear cell renal cell carcinoma and urothelial carcinoma (1, 15).

Our study complements the literature limited data on individual experience of regional centers specialized in renal tumor pathology (16-18). In this context, we draw attention to the fact that for clear cell renal carcinoma and urothelial carcinoma we

registered different percentages, higher compared to reported data in the literature (86.27% versus 70-75%, 28.81% versus 10% respectively). These figures point out the possibility of identifying epidemiological features with regional / national specificity, thus opening perspectives of deepening the study.

CONCLUSIONS

Although our study did not include uncommon or rare histological variants, their existence cannot be unnoticed - pathologist theoretical knowledge providing the basis for a diagnosis based on operational criteria of the most recent classification.

INTRAOCULAR BIODISTRIBUTION OF INTRAVITREAL INJECTED FLUORESCENT DEXAMETHASONE-CHITOSAN NANOPARTICLES IN RABBIT EYES (Abstract): **Aim:** To evaluate intraocular biodistribution of fluorescent nanoparticles composed of dexamethasone bound to chitosan after intravitreal administration in rabbit eyes. **Material and methods:** The chitosan and gelatin based nanoparticles were synthetized using a reverse emulsion-double crosslinking technique (ionic and covalent) and then dexamethasone was bound. Two units of 1% suspension of these nanoparticles in saline solution were injected intravitreally into rabbit eyes. The histologic sections obtained at 72 hours were analyzed by confocal microscopy. **Results:** The chitosan-fluorescein conjugate bound to dexamethasone was present in all ocular tissues at 72 hours. The nanoparticles were present in the retina and lens in a larger amount than in the other ocular tissues. **Conclusions:** The reverse emulsion-double crosslinking technique was efficient in synthesizing a biocompatible polymeric nanosystem. The *in vivo* study of intraocular biodistribution of fluorescein-marked nanoparticles capable of binding dexamethasone revealed their affinity for the retina and lens after intravitreal administration. **Keywords:** BIODISTRIBUTION**,** INTRAVITREAL, NANOPARTICLES, DRUG DELIVERY, CHITOSAN, DEXAMETHASONE

Nanoparticles are nanometer sized molecules that behave as a whole unit with respect to their properties and transport behavior. These molecules are beginning to be more frequently studied and used in the therapy of many diseases as safe and efficient drug carrier systems. Recent studies have demonstrated the ability of nanoparticles to overcome the eye barriers (cornea, conjunctiva, sclera and the blood-retinal barrier), thus being able to deliver therapeutic agents to the different ocular tissues. (1-5).

Current research trends in ophthalmology aim at developing intraocular drug delivery systems able of exerting their pharmacological effect over a longer period of time at a lower administration rate and with

a lower dose related toxicity rate.

The most recent therapies of choroidal and retinal neovascularization target the main pathogenic processes of the disease: inflammation and overexpression of pro-angiogenic factors. In addition to the anti-angiogenic and anti-inflammatory agents approved for use (ranibizumab, aflibercept, steroids) or widely used in "off-label" manner (bevacizumab) there are numerous ongoing researches on other potential pathogenic factors (platelet-derived growth factor, complement modulators).

The aim of this experimental study is to assess the intravitreal biodistribution of fluorescent chitosan nanoparticles loaded with dexamethasone and injected in rabbit eyes. These nanoparticle-dexamethasone systems are considered potential therapeutic agents for ocular neovascularization and its complications.

MATERIAL AND METHODS

1. Preparation of dexamethasone fluorescent nanoparticle. The polymers used for the preparation of nanoparticles were chitosan and gelatin. These polymers were chosen because they combine the benefits of proteins and those of polysaccharides, in order to obtain a good bioavailability and drug release capacity to target ocular tissues.

Chitosan is a linear polysaccharide obtained from crustacean shells. It is composed of randomly distributed β-(1-4)-linked D-glucosamine (deacetylated unit) and N-acetyl-D-glucosamine (acetylated unit). Gelatin is a polypeptide prepared by thermal, chemical and physical denaturation of collagen. In the preparation process a series of emulsifiers and surfactants were also used. A 10% fluorescein solution was used to mark the chitosan-gelatin nanoparticles.

Chitosan and gelatin nanoparticles were synthesized using the double crosslinking in the droplet method. This method was selected due to the low toxicity required by ophthalmic preparations.

The heterogeneous reaction system involved two emulsions. The aqueous phase of the first emulsion was represented by the solution of the two natural polymers, gelatin and chitosan (polymer concentration 0.5 %). The organic phase of the first emulsion, consisting of toluene and the specific amount of surfactant Span 80 was added to the aqueous solution and stirred at 15 000 rpm for 10 minutes. The thus obtained primary emulsion was dripped by syringe into a 600-ml Berzelius beaker, stirred ultra-fast for 10 minutes in order to obtain the secondary emulsion in the organic phase, represented by a volume of 260 ml toluene and the appropriate surfactant, Span 80, 2%.

After the emulsification of the two emulsions, ionic crosslinking was carried out using sodium phosphate (5%), while stirring (5000 rpm/10 min). Glutaraldehyde was dripped into the reaction vessel while stirring in order to complete the covalent crosslinking.

After the double cross linked particles were obtained, separation was done by centrifuging and purification of the particles in several stages consisting of successive cycles of washing with double-distilled water /acetone/n-hexane to remove traces of toluene and centrifugation (5000 rpm). Drying of nanoparticles was carried out in n-hexane at room temperature.

The nanoparticles were marked with fluorescein, which was covalently bound to chitosan. Fluorescence was necessary to assess the biodistribution of nanoparticles within the eye.

Chitosan–fluorescein conjugate was synthesized using a method adapted from

De Campos et al. (2004) (6). The resulting product was dialyzed using a dialysis membrane in the form of tubes with a pore size of 12,000 Da. The last step was the lyophilization of the product. Chitosan fluorescein staining was highlighted by infrared spectroscopy.

Using double crosslinking in the double emulsion process, as described above, fluorescent nanoparticles were obtained by introducing in the reaction a fluorescein-labeled chitosan.

Afterwards, dexamethasone was bound to the fluorescent nanoparticles by immersing 100 mg nanoparticles in 9 ml solution of dexamethasone for 48 hours. Then, the suspension was centrifuged and the supernatant weighed.

2. Study of in vivo release of dexamethasone loaded fluorescent nanoparticles. The study was conducted in accordance with the Declaration of Helsinki, the current modifications (Somerset West Amendment). We used a group of 5 rabbits bred in laboratory under the same conditions and fed with standard food. Each rabbit received a 0.03 ml intravitreal injection of 1% solution of dexamethasone-loaded nanoparticles in the right eye. Before performing intravitreal injections the animals were anesthetized with intraperitoneal ketamine 25 mg / kg.

The animals used in the experiment were sacrificed 72 hours after the injection of fluorescent nanoparticles after prior anesthesia with Ketamine 25 mg/kg. The right eye was harvested, transferred to ice and sectioned within 15 minutes.

The tissue samples were then treated with mouse anti-fluorescein monoclonal antibodies, which were washed after 48 hours followed by a new treatment with secondary goat anti-mouse antibodies and labeled with R- phycoerythrin.

The sections were then transferred to microscope slides and coated with the fluorescence medium. To highlight the fluorescence, a confocal microscopy setup was used, including an inverted Nikon Eclipse TE-300 microscope.Images capture was done using red fluorescence (for R-phycoerythrin) and transmitted light in order to distinguish the morphological features.

RESULTS

Analysis of the biodistribution of fluorescent dexamethasone loaded-nanoparticles within tthe eye. Following the intravitreal injection and analysis of the obtained histological sections, the fluorescent dexamethasone-nanoparticles were found to be uniformly distributed and present in all ocular tissues. Red fluorescence was present in all ocular tissues of the experimental animals at 72 hours (fig.1 A, B; fig.2 A, B; fig.3 A, B; fig.4 A, B).

The intraocular biodistribution of dexamethasone nanoparticles recorded the highest values in the lens and retina, as seen at both the microscopic examination of histological sections and RGB diagram. A fluorescence value of 17.35 ± 1.85 UA inside the lens and 13.08 ± 3.75 UA in the retina was recorded, showing a better fixation of the drug loaded nanoparticles within the tissues surrounding the injection site.

In the structure of cornea and sclera a significant amount of dexamethasone loaded nanoparticles was detected, but lower compared with the retina and lens. Recorded values were 9.75 ± 3.24 UA for the cornea and 11.78 ± 2.94 UA for sclera, thereby highlighting the migration of nanoparticles in all ocular tissues at 72 hours after injection.

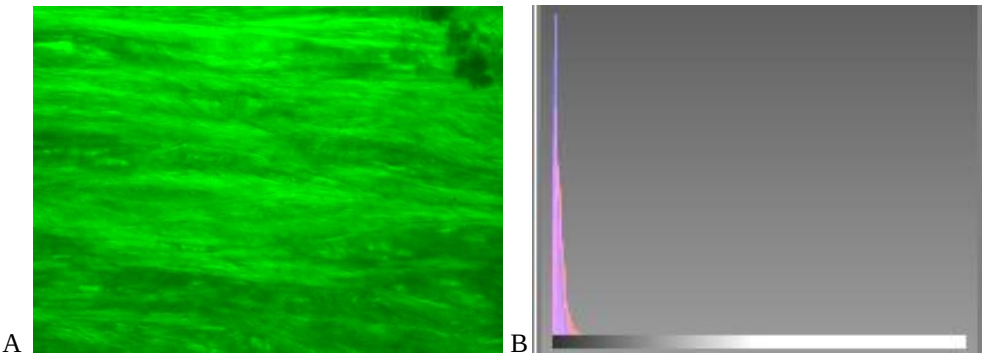

Fig. 1. A. Analysis of red fluorescence from cornea section of the right eye at 72 hours (40x) (9.75±3.24 UA, n = 5). B. Cornea RGB at 72 hours.
Red fluorescence is present at medium intensity.

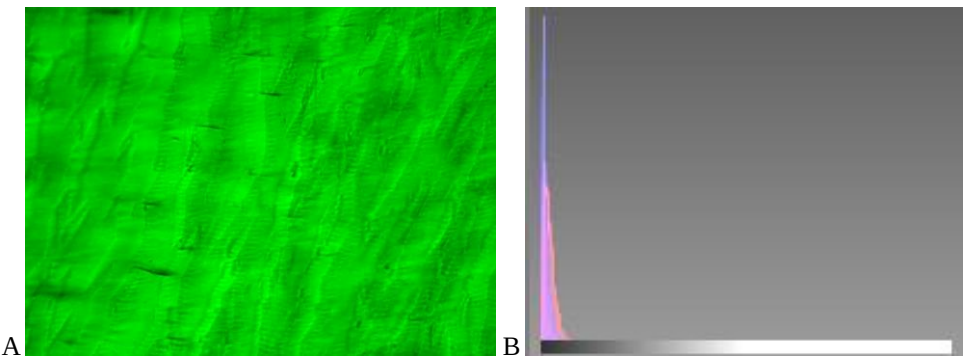

Fig. 2. A. Analysis of red fluorescence from lens section of the right eye at 72 hours (40x) (17.35 ± 1.85 UA, n = 5). B. Lens RGB at 72 hours.
Red fluorescence is present and intense.

DISCUSSION

Nanoparticles are currently studied in terms of efficiency as carriers of many drugs with application in ophthalmology and other medical specialties. Specific controlled release properties depend on the physicochemical properties of the drug, the chemicals used in the synthesis of the nanoparticles, as well as the methods of preparing such polymer systems. In general, when using optimal drug loaded nanoparticles the ocular bioavailability of many drugs significantly increases compared to conventional formulations. Increased ability for overcoming the blood-retinal barriers and releasing biologically active principles in a safe and effective manner that opens new opportunities in the treatment of many ophthalmic diseases.

The blood-retinal barriers consist of an inner segment constituted of retinal endothelial cells, pericytes and astrocytes and an outer segment composed of the tight junctions between the retinal pigment epithelium cells. This barrier acts as a filter that restricts permeability of high molecular weight particles, including drugs, to the retina. Drug loaded nanoparticles of the appropriate size were proved to have favorable biological properties as prolonged residence time in the vitreal gel, higher availability of the drugs to the deeper layers of the retina and decreased toxicity (7-9). Also, these carriers can improve the availability of poorly water-soluble molecules to the retinal layers (10).

Nanopolimeric systems structured on chitosan and gelatin are used in the pharmaceutical composition of many hydrogels as drug carriers due to their property of being absorbed and metabolized without resulting toxic products. The blending of chitosan with gelatin increases the stability of the gel (11, 12).

Dexamethasone is a glucocorticosteroid with anti-inflammatory and immunosuppressive properties. In ophthalmology, is widely used in the topical treatment of various inflammatory diseases. The intravitreal administration of dexamethasone is used in the treatment of macular edema secondary to vascular occlusions, diabetes, uveitis. Its effectiveness in the treatment of disorders of the posterior segment of the eye is due to a reduction in vascular permeability and leukocyte accumulation, by acting simultaneously on both VEGF and cytokines path (13).

Particles stable in size and shape were obtained using the double crosslinking (covalent and ionic) in double emulsion technique. This method proved to be efficient due to covalent surface crosslinking. Also, the high swelling capacity of the nanoparticles is due to ionic crosslinking which enable a large diffusion capacity of drugs.

The histological samples were treated by indirect immunofluorescence to investigate the presence or absence of fluorescent drug- loaded nanoparticle in their structure. Tissue samples were then subjected to direct microscopy (by transmitted light) in order to highlight their morphological structure and confocal microscopy to assess the presence of fluorescently loaded nanoparticles inside ocular tissues. The presence of fluorescent dexamethasone nanoparticles was detected in the ocular tissues of experimental animals at 72 hours by marking red fluorescence.

Following intravitreal injection of fluorescently labeled polymer-drug nanosystems and analysis of the histological sections obtained from the rabbit eyeballs we found them to be uniformly distributed and present in all ocular tissues.

Comparing the results obtained at 72 hours after intravitreal administration of the fluorescent polymer-drug system with those achieved in our previous experimental study, in which only fluorescein loaded nanoparticles were injected in Wistar rat eyes, we concluded that the fluorescence values attained in the second experiment were higher (14). In both experiments the nanoparticles were predominantly fixed in the structure of retina and lens, but the fluorescence value was higher with a medium of 9 UA when dexamethasone was bound to the polymer. Although cornea and sclera presented a lower fluorescence than retina and lens in both experiments, higher values, in medium with 7 UA, were also registered when dexamethasone nanosystems were administered.

The higher values of fluorescence obtained in this experiment suggest that the dexamethasone carrier nanoparticles are stable and have the ability to persist in the tissues long enough to deliver the loaded drugs.

The results of this study are consistent with existing literature on the subject. Binding dexamethasone to polymeric nanoparticles systems has the effect of increasing the drug action period after intraocular injection. Experimentally, it was demonstrated that dexamethasone-loaded nanoparticles can inhibit the development of subretinal neovascularization, the effect being dose dependent (15). The bioavailability of the therapeutic substance is increased by its binding to the polymer carrier, dexamethasone nanoparticles are gradually released over a period of up to 50 days, with maintenance of stable therapeutic doses at least 30 days (16).

CONCLUSIONS

In our study dexamethasone carrier nanoparticles injected intravitreally were found mainly in the lens and retina at 72 hours after administration. Smaller amounts were found in the cornea and sclera at the same interval of time after administration.

We demonstrated the ability of drug-polymer systems to penetrate tissues in the immediate vicinity of administration site and migrate, especially in the retinal and lens structure, at 72 hour interval. Their stability is higher after drug binding to the polymeric structure. Also higher levels of

fluorescence were recorded in this case compared to the values obtained when only fluorescein-loaded nanoparticles were administered.

INTRAORBITAL FOREIGN BODY (Abstract): Penetrating orbitocranial injuries caused by intraorbital foreign body are a rare cause of morbidity being most common among young people. The term intraorbital foreign body refers to a foreign body that occurs within the orbit but outside the ocular globe. We report the case of a 12-year-old male child who sustained a right cranial facial trauma due to accidental fall on a piece of wood, which penetrated intraorbitally. Native cranial magnetic resonance imaging (MRI -1.5 T) revealed the presence of an intraorbital foreign body, 6 cm long and 1.5 cm wide, near the orbital apex. In our patient, early surgical extraction of the foreign body had a decisive role on his full recovery.In this case, although a large foreign body penetrated the entire length of the orbit, it did not cause damage to any intraorbital structure. Vision and right ocular globe function had an excellent prognosis. **Keywords:** INTRAORBITAL FOREIGN BODY, ORBITAL TRAUMA, VISUAL ACUITY.

CASE REPORT

We report the case of a 12-year-old male child who sustained a right craniofacial trauma due to an accidental fall while playing with another child on a stake set firmly in the ground. During the impact, a wooden fragment 6 cm long and 1.5 cm wide penetrated intraorbitally the anterior right maxillary sinus wall and then the right orbital floor up to the orbit apex.

On local examination, the external end of the foreign body was seen just below the right lower orbital rim. The right eye was painful and showed significant palpebral edema and erythema (fig. 1).

Fig. 1. The patient photography at the first examination: a wooden foreign body, below the right lower orbital rim.

The ophthalmologic examination revealed preservation of visual acuity of the

right eye (V.A.R.E.=1) and no pathologic changes on slit-lamp biomicroscopic and ophthalmoscopic examination.

Native cranial computed tomography (CT) scan showed a right intraorbital hypodensity with a trajectory parallel to the interior wall of the orbit, medial to the right internal muscle up to the orbit apex, involving the scleral wall and a temporal aerial bulla.

Native cranial MRI (1.5 T) revealed the presence of an intraorbital foreign body which did not cause damage to the intraorbital vascular and nerve structures (fig. 2, 3, 4).

The child was admitted and the administration of antibiotics (clindamycin and metronidazole) was initiated.

Fig. 2. Sagittal T1 MRI, intraorbital foreign body (arrow).

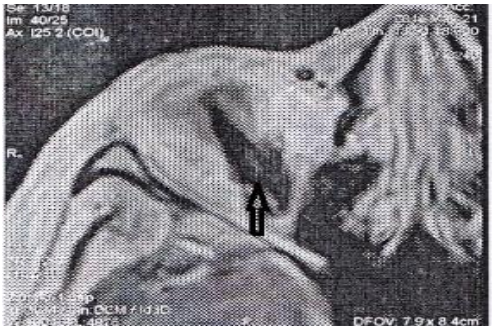

Fig. 3. Axial T1 MRI, intraorbital foreign body (arrow).

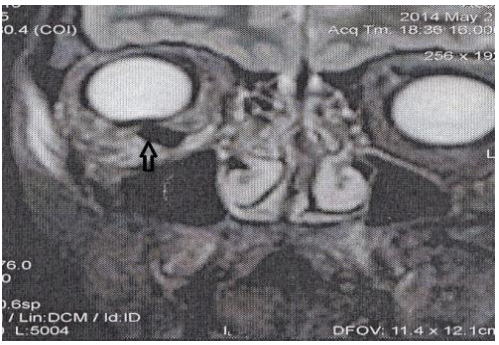

Fig. 4. Coronal T1 MRI, intraorbital foreign body (arrow).

Surgery was performed 24 h after the accident and consisted in the removal of the foreign body (wooden fragment) by enlarging the entry point (fig. 5, 6).

Fig. 5. Wooden foreign body extracted from the orbit.

Fig. 6. The post operative results.

The postoperative course was favorable, the patient being discharged 5 days after surgery.

Upon discharge, the patient showed diplopia, with left eye (L.E.) fixer and right eye (R.E.) sursumvergent +13°.

One month after discharge, diplopia remitted and visual acuity of the right eye remained 1.

DISCUSSION

Penetrating orbitocranial injuries caused by an intraorbital foreign body are a rare cause of morbidity and they occur mostly in children and adolescents.

Penetrating orbitocranial injuries are more common in people involved in military services, but they may also occur in civil life, where they usually take the form of accidents. The occurrence mechanism relies on high velocity forces like work accidents, injuries caused by weapons or even simple injuries (household accidents, play accidents). Accidents caused by intraorbital foreign bodies are more common in men than in women and young people, as compared to senior citizens.

Depending on the material, intraorbital foreign bodies may be classified into: inorganic metallic (iron, aluminum, steel, etc.), nonmetallic (plastic, glass, rock, etc.) and organic (wood, plants, thorns, etc).

The orbit is a cranial cavity where the eye and eyeball adnexa are located. Although the orbit is described as a pyramid, its walls are not exactly straight. The walls, tip and basis are curvilinear and they are pierced by foramens and fissures. An anatomical characteristic of the orbit is that structures are arranged in groups of seven: seven bones (frontal, ethmoid, lacrimal, sphenoid, zygomatic, palatine and maxillary), seven intraorbital muscles and seven nerves, respectively (1).

Foreign bodies located in the anterior 2/3 of the orbit may be approached extracranially, whereas those located in the apical area, especially in the medial section of the optic nerve, require a transcranial approach. Orbital injuries extending beyond the upper orbital fissure require a combined and complex surgical approach due to their closeness to the cavernous sinus.

The presence of the periorbita allows the classification of orbital injuries into intradural (deep in the periorbita) and extradural (when they are located between the periorbita and osseous orbit). In its turn, the muscular cone divides the orbit into two areas, the intraconal and the extraconal one. Whereas intraconal injuries are always intradural, extraconal injuries may be intra- or extradural. The intraconal area may also be divided in relation with the optic nerve into a medial, central and lateral area (2) (Figure 7).

The transcranial approach is preferred when the injuries are located at the top of the orbit and/or of the optic foramen. A direct approach through the lateral wall of the orbit requires lateral orbital margin and wall osteotomy and it is preferred when the foreign bodies are located in the upper, temporal or lower compartment and in the lateral side of the apex (3).

There are 2 basic types of surgical orbital approaches: transorbital, preferred by ophthalmologists, and extraorbital, preferred by neurosurgeons.

These are the primary transorbital approaches (3, 4):

-anterior orbitotomy without osteotomy:

-superior-incision through the eyelid, supra-orbital or sub-frontal incision,

-inferior-transconjunctival incision, subciliary incision or incision through the

lower eyelid,

-anterior orbitotomy with osteotomy of the upper orbital edge (for larger foreign bodies),

-lateral orbitotomy,

-medial orbitotomy,

-combination between lateral and medial orbitotomy.

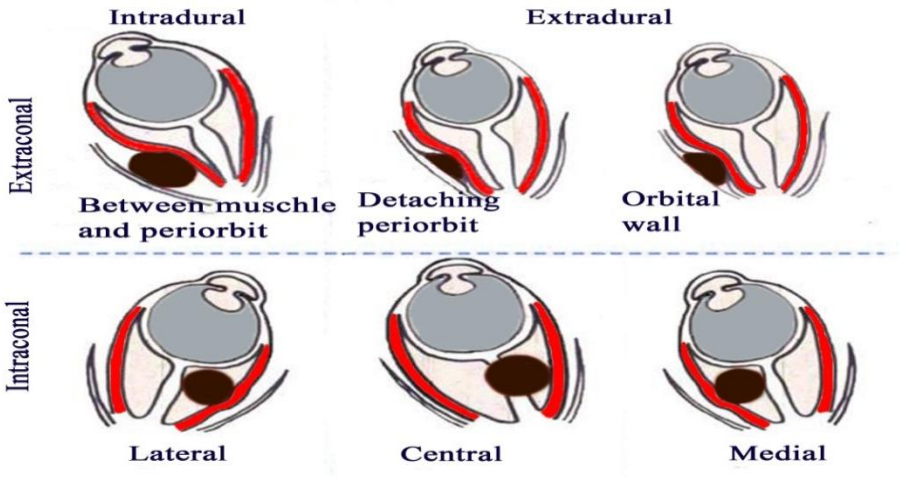

Fig. 7. Topographic classification of intraorbital lesions.

Extraorbital approaches are possible through a frontotemporal approach with or without orbital osteotomy and through a lower orbital approach. Extraorbital approaches may also be supported by endoscopic methods (4).

The approach path is set after the imaging assessment of the intraorbital injury, which reveals both the foreign body and its relations with the neighboring anatomical structures.

Eye Ultrasonography (US)

Although ophthalmic ultrasonography plays a well-determined role (5), as it provides real-time information about the eye and the orbit (especially about the intraocular structures), it may also be used during the surgical procedure. Here are some of the disadvantages of eye ultrasonography performed in case of injury caused by an intraorbital foreign body: foreign body migration (due to the probe moving around) and lack of information related to orbit fractures.

Computed Tomography (CT)

Unlike eye ultrasonography, computed tomography is available in most hospitals, does not require direct contact with the orbit, eyeball or foreign body, is superior to US in determining the size and shape of the foreign body, allows easier orbital fracture diagnosis, and is faster and cheaper than the MRI.

CT scanning should ideally observe the standard orbit examination protocol, according to which both the axial and coronal sections should be 1.0-1.5 mm. Nevertheless, foreign bodies smaller than 0.5 mm and plastic foreign bodies may be overlooked, whereas organic (wood) bodies

may have false negative results. Due to the air-containing wood cellulose matrix, the wood foreign body may be taken for pneumoorbita (6). Another disadvantage would be that orbit CT cannot be done in the operating room, the intraorbital structures are not viewed as by an eye US, and artifacts from metallic foreign bodies may occur. CT scan is recommended for: intraorbital foreign bodies, eye ball ruptures/dilacerations and orbit fractures (7).

Magnetic resonance imaging (MRI)

MRI exploration is indicated when a ferromagnetic foreign body or a foreign body of mixed organic-inorganic composition is excluded. Some of the advantages of examination by MRI are: axial, coronal and sagittal images and patient repositioning is not required (as in coronal CT sections), provides higher quality images of soft tissues compared to CT. The disadvantages of MRI exploration are: motion artifacts, long time of image acquisition and non-specificity for orbit fractures. The MRI characteristic aspect of dry or moist wood is the hypo dense signal related to intraorbital fat. T1 sections are more useful than T2 as they provide a better contrast between wood and intraorbital fat. Should there by the least suspicion of vessel injury, CT or MRI angiography are recommended to assess vascular integrity (3).

TREATMENT

The prevention of endophthalmitis is the main objective of early surgery, although recent studies found no difference between the surgery performed within the first 48 hours and surgery performed after this time interval. In all patients diagnosed with an intraorbital foreign body, antibiotic therapy must be initiated, due to the higher incidence of secondary orbital infections (5).

The surgical approach is selected based on the nature of the foreign body, its location (anterior or posterior orbit) and complications (infections, injury or compression of the optical nerve, injury to the extraocular nerves or intraorbital vessels). Asymptomatic metallic (mostly the small ones) and inert foreign bodies located within the posterior orbit may be left *in situ* and kept under control.

On the other hand, organic foreign bodies (wood or other vegetable matter) cause an intense inflammatory reaction and are not tolerated. Organic wooden foreign bodies determine a fast infection in the orbit due to its spongy texture and organic nature, which is a good environment for microbial agents (8). They may cause panophthalmia, intraorbital abscess or fistula, reason why their extraction is a surgical emergency (9).

A surgical challenge may be the transorbital penetrating intracranial injury. In this circumstance, only a multidisciplinary team may conduct a safe and successful surgery. In such cases, the upper orbital fissure and the optical channel may be gateways to the intracranial space, mostly to the cavernous sinus and the internal carotid artery (cavernous, clinoid and ophthalmic segment).

CONCLUSIONS

The patient presented to hospital immediately after the accident, which made possible the immediate initiation of antibiotic and antimycotic therapy, a possible endophthalmitis being thus prevented. The diagnosis was penetrating craniofacial trauma with a wooden intraorbital foreign body, the damage to the ocular globe supported by initial physical examination be-

ing refuted by radio-imaging investigations.

Surgical treatment is indicated in case of foreign bodies of large sizes, with cutting edges, in the presence of signs of inflammation or infection, intraorbital abscess or contrast medium uptake in the foreign body, palpable orbital mass, restricted motility, proptosis, chemosis, compression of the optical nerve, fistula, suspicion of a wooden, copper or vegetable foreign body (7).

The intraorbital foreign body as a result of a penetrating trauma is a therapeutic emergency, and the removal of an organic foreign body is a surgical emergency. The first recommended imaging method of diagnosis is computed tomography. The diagnosis and early surgical treatment influence the course and prognosis of patient's vision.

This case is peculiar because, although a large foreign body passed through the entire length of the orbit and important anatomic structures, it did not cause damage to any intraorbital structure. Vision and right ocular globe function had an excellent prognosis.

THE ROLE OF VITAL STAINING IN THE EARLY DIAGNOSIS OF ORAL CANCER (Abstract): The early diagnosis of oral cancer is a priority for the entire dental system. Dental specialists, who most often are the first to examine the patients with oral tumors, are responsible for their patients' future and it is not only expected but also desired that they fulfil their role with a lot of commitment, competence and professionalism. On the other hand, it is also essential to continue developing, assessing and improving the main means of primary and secondary prophylaxis and to identify and diagnose oral cancer at an early stage. Since nowadays the fight against oral and maxillofacial cancer can only be won if it is diagnosed at an incipient stage and it is followed by a radical multimodal and effective treatment, the population must be more sensitive to the oncogenic risk factors of the oral cavity and to the early manifestations of cancer. **Keywords**: VITAL STAINING, EARLY DIAGNOSIS, ORAL CANCER.

The early diagnosis refers to the diagnose made as soon as possible after a clinical manifestation when the lesion can be seen and/or palpated or when it can be noticed using laboratory tests, before reaching the maximum T_1limit, with N_0 and M_0 (1). The toluidine blue vital staining (RICHART) relies on its affinity for cell nuclei and for those nuclei undergoing mitosis (2, 3). Colour intensity is directly proportional with nuclei density, size and their division phase, that is, with their degree of malignity. The method can identify lesions of 1 mm^3 this way reducing the lower limit of detecting tumors up to the "infraclinical" stage, at an age of the tumor of almost 6 months (4).

In dentistry, toluidine blue vital staining is to be considered in the diagnostic process, completing in a useful and necessary manner the clinical examination. It requires further investigations of the suspected lesion (5, 6).

To ease the detection and the identification of risk lesions, additional methods have been introduced: toluidine blue vital staining is the most studied method that can support the early detection of premalignant lesions and squamous cell carcinoma (7, 8, 9). Toluidine blue is a cationic metachromatic dye that may selectively bind to free anionic groups such as sulfate, phosphate

and carboxylate radicals of large molecules (10). *In vivo*, toluidine blue stains nucleic and deoxyribonucleic acids which can be retained in intracellular spaces of dysplastic epithelium. Dysplastic and malignant tissues retain toluidine blue because of the loss of tumor suppressor genes that predict the progression of precancerous lesions towards carcinoma or represent the squamous cell carcinoma themselves during the diagnosis (11, 12).

MATERIAL AND METHODS

Toluidine blue is recommended for the following reasons:

- It determines premalignant oral lesions at risk of turning into squamous cell carcinoma;
- It identifies mucosal lesions with high risk molecular models with a significant potential of turning into cancer (for both high and low risk dysplasia) (13, 14);
- It evaluates the extent and the margins of carcinoma and premalignant lesions;
- It guides the biopsy site selection and accelerates the decision to biopsy (15).

The toluidine blue vital staining or the Richart test was used on 268 patients divided into three groups of physically examined patients (tab. I):

TABLE I

Groups of patients

	Patients
Group I	25
Group II	156
Group III	87
Total	*268*

From the total 268 clinical lesions, 53 had a hyperplastic vegetant appearance while 192 had an ulcerative appearance; 23 patients presented white lesions. The diagnosis made after physical examination is presented below (tab. II):

TABLE II

Diagnosis after clinical exam

Diagnosis	Patients
Traumatic ulceration on the lower lip, tongue, cheek	103
Chronic cheilitis	24
Herpetic ulceration	15
Post-burn ulceration (hard palate, tongue)	9
Aphthous stomatitis	9
Ulcerous stomatitis	23
Leukoplakia	21
Lichen planus	11
Hyperplastic benign tumors (lip, tongue, vestibule, gingivoalveolar)	53
Total	*268*

The Richart test was used for:

- completing the physical exam of benign lesions that still presented a certain degree of malignant suspicion
- identifying small, ulcerative relapse signs
- the stomatoscopic analysis of certain lesions.

The following work technique was used: we cleaned the lesion with a piece of gauze soaked in 1% acetic acid; after cleaning the area, using the water spray of the dental unit (dentior), we have isolated the lesion and dried it with warm air. The lesion was colored using a sponge saturated with toluidine blue aqueous solution. The dye was kept for 2-3 minutes after which the lesion was washed once again using the spray and then dried uniformly and without applying any pressure with a solution of 1% acetic acid.

Here are some of the cases where the Richart method was used.

1. I. I., Iasi town, came in for consultation for an ulcerative lesion, painful manifestation on the left cheek, and swelling of the surrounding mucosa, present for a few days (fig. 1). After cleaning the dye (fig. 2) we noticed a second ulcerative lesion of 2 cm in diameter which stained dark blue (positive reaction) (fig. 3). A 7 days treatment including rinses with 5% tetracycline solution led to the healing of the ulceration. The diagnosis was ulcerative stomatitis. Although the dye was retained in the central area leading to a misinterpretation of malignant lesion, in fact it was an inflammation of the oral mucosa. In this case, the toluidine blue response was false positive.

Fig. 1. The ulcerative lesion

Fig. 2. Toluidine blue aqueous solution

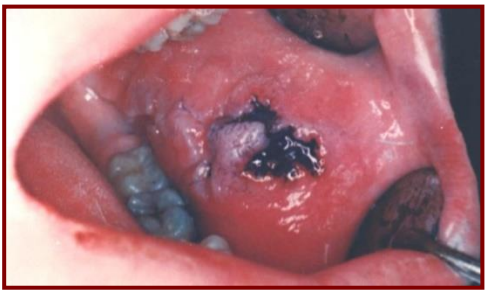

Fig. 3. Ulcerative lesion of 2 cm - stained dark blue (positive reaction)

2. S. N., Iasi county, pensioner, smoker for over 50 years and alcohol user presented with an ulcerative lesion of less than 1 cm in diameter, round, with slightly pronounced edges, without hardened base, unpainful, situated in the medial 1/3 segment of the lower lip, with the surrounding mucosa of normal appearance (fig. 3). The lesion had been present for almost 3 years. We proceeded using toluidine blue to dye the ulceration, washed the excess with acetic acid, and it resulted a dark blue stain (positive reaction) (fig. 4). Exfoliating cytology made the diagnosis of inflammatory smear with hematins, superficial and intermediary epithelial cells of normal appearance. Treatment: removal of the ulceration using a type "V" resection on the lower lip and suture of the margins.

Fig. 4. Dark blue stain (positive reaction)

The histopathological examination made the diagnosis of moderately differentiated squamous cell carcinoma with intense superficial ulceration. In this case,

the intense positive staining and the carcinoma diagnosis correlated well.

3. C. V., from Vaslui County, retired, smoker, was examined for an oval superficial ulceration of less than 1 cm in size, located on the red part of the lower lip, the surrounding mucosa having a whitish leukoplastic appearance. The lesion was noticed a few months earlier, increased in size gradually, and was slightly bleeding (fig. 5). Physical examination was completed with the toluidine blue vital staining which, after the removal of the extra amount of substance with acetic acid, remained fixed in the ulceration area. The toluidine blue vital staining was considered positive (fig. 6).

Fig. 5. Oval superficial ulceration

Fig. 6. Blue stain (positive reaction)

Treatment: excision of the ulceration from the lower lip until healthy tissue was reached. The histopathological examination led to the diagnosis of chronic ulcerative cheilitis. Although the lesion retained the dye, the reaction was *false positive* as, in the end, it turned out to be a chronic inflammation and not a malignant ulceration.

4. H. M., Iasi town, retired, non-smoker, presented with a leukoplastic area from the left edge to the ventral side of the tongue and for an ulceration of less than 1 cm in diameter on the dorsal surface of the tongue, evaluated as superficial and painful. We used the Richart test. After using acetic acid to remove the excessive dye the remaining area appeared atypical: the ulceration did not retain the dye (negative reaction) and the tip of the tongue and certain areas on the edge of the tongue as well as the leukoplastic area stained light blue (positive reaction). When analyzing the reaction 24 hours later we found that the entire area that reacted to toluidine blue regained its normal appearance (as before staining). Treatment: excision of the ulceration along with the leukoplastic area on the edge of the tongue. The histopathological examination led to the following diagnose: leucoplakia and dysplastic lesions and intraepithelial invasive carcinoma. In this case, the *atypical* Richart test was the reason why we decided to biopsy.

5. I. D., from Bacau County, smoker for 10 years, type II diabetes and third-degree obesity presented with a 1.5 cm-long ulceration situated on the ventral side of the tongue in the left half, near the tip of the tongue. The patient noticed the appearance of lesion almost a year before, but it became painful and increased in size recently. Physical examination revealed that the ulceration was highly connected to 3.5 (tooth in lingual position). The ulceration was stained with toluidine blue and then washed with 1% acetic acid solution. The ulceration did not retain the stain (negative reaction) and the surrounding mucosa

stained light blue. Exfoliative cytology demonstrated it was an inflammatory smear. Indeed it was a traumatic ulceration caused by the presence of tooth 3.5 in a vicious position and the ulceration healed in 10 days after tooth extraction.

6. C.I., Suceava County, retired, 40-year smoker and alcohol consumer on daily basis (200 g.), noticed for 3 months before the presentation the appearance of a small ulceration on the right side of the tongue in relation to 4.4 (with deep chronic marginal periodontitis), 4.3, 4.2, 4.1 (residual tooth roots). The lesion gradually increased in size developing a crater-like appearance. The Richart test was used. After removing the dye with acetic acid, the dorsal part of the tongue and the right edge along with the ulceration were stained light blue (very light) stained – the reaction being interpreted as negative. The cytological exam indicated tumor cells in the oral smear with free atypical cells and in placard. Treatment: surgical removal of the ulcer area. The histopathological examination made the diagnosis of undifferentiated squamous cell carcinoma developed deep in the chorion infiltrating strictly the muscle tissue. In this case, although the Richart test was negative, the ulceration was, in fact, a malignant lesion.

7. A. A., Iasi town, retired, smoker for 7 years, presented with a ulceration of 0.5 cm in diameter, irregular margins, the surrounding mucosa being slightly congestive, painful on palpation, situated on the edentulous alveolar crest corresponding to 4.8 (extracted 2 months earlier). During the examination the dental instrument was introduced 5 cm deep into the tooth socket. The dye was introduced and after washing it with acetic acid the ulceration appeared to have a normal (negative appearance). The cytological examination indicated an inflammatory smear. In this case, the negative result of the Richart test corresponded to the cytodiagnosis (inflammatory smear) and clinical course (the lesion healed 2 weeks later).

RESULTS

Considering the analyzed clinical lesions, the results for toluidine blue vital staining were as follows: (tables III-XI):

TABLE III

Clinical diagnosis versus true diagnosis: Ulcerations

Clinical diagnosis			***True diagnosis***		
Of 103 ULCERATIONS			87 malignant lesions and 16 inflammatory lesions		
Test	Stain	No. of patients	Lesion	No. of cases	Reaction
(+)	Dark blue	76	Malignant lesions	72	(+)
			Inflammatory lesions	4	False (+)
	Light blue	13	Malignant lesions	4	(+)
			Inflammatory lesions	9	False (-)
(-)	Uncoloured tissue	8	All cases were malignant lesions but did not retain the dye	8	False (-)
Uncertain	Atypical coloration	6	Malignant lesions	3	Atypical
			Mucosal inflammations	3	

TABLE IV

Clinical diagnosis versus true diagnosis: Cheilitis

Clinical diagnosis			***True diagnosis***
Of 24 CHEILITIS CASES			21 chronic inflammations and 3 cases that degenerated into carcinoma *"in situ"*
Test	Stain	No. of patients	
(+)	Blue	3	Carcinoma *"in situ"*
(-)	Uncoloured tissue	16	Cheilitis
Uncertain	Atypical coloration	5	Cheilitis

TABLE V

Clinical diagnosis versus true diagnosis: Leukoplakia

Clinical diagnosis			***True diagnosis***
Of 21 LEUKOPLAKIA CASES			12 leukoplakia and 9 cases that degenerated into carcinoma *"in situ"*
Test	Stain	No. of patients	
(+)	Dark blue	9	Carcinoma *"in situ"*
	Light blue	3	Leukoplakia – false reaction (+)
(-)	Uncoloured tissue	9	Leukoplakia

TABLE VI

Clinical diagnosis versus true diagnosis: Liken Planus

Clinical diagnosis			***True diagnosis***
Of 11 LICHEN PLANUS CASES			
Test	Stain	No. of patients	
(+)	Light blue	5	Lichen planus – false reaction (+)
(-)	Uncolored tissue	6	Lichen planus

TABLE VII

Clinical diagnosis versus true diagnosis: Herpetic ulcerations

Clinical diagnosis			***True diagnosis***
Of 15 herpetic ulcerations			
Test	Stain	No. of patients	
(+)	Dark blue	5	Ulcerations – false reaction (+)
(-)	Uncolored tissue	10	Ulcerations

TABLE VIII

Clinical diagnosis versus true diagnosis: Post-burn Ulcerations

Clinical diagnosis			***True diagnosis***
Of 9 post-burn ulcerations (hot food, cigars etc.)			
Test	Stain	No. of patients	
(-)	Uncoloured tissue	9	Ulcerations

TABLE IX

Clinical diagnosis versus true diagnosis: Aphthous stomatitis

Clinical diagnosis			***True diagnosis***
Of 9 APHTHOUS STOMATITIS			
Test	Stain	No. of patients	
(+)	Light blue	6	Aphthae (inflammation) – false reaction (+)
(-)	Uncolored tissue	3	Aphthae (inflammation)

TABLE X

Clinical diagnosis versus true diagnosis Ulcerative stomatitis

Clinical diagnosis			***True diagnosis***
Of 23 ULCERATIVE STOMATITIS			
Test	Stain	No. of patients	
(+)	Light blue	9	Inflammatory lesions – false reaction (+)
(-)	Uncoloured tissue	10	Inflammatory lesions
Uncertain	Atypical coloration	4	Inflammatory lesions

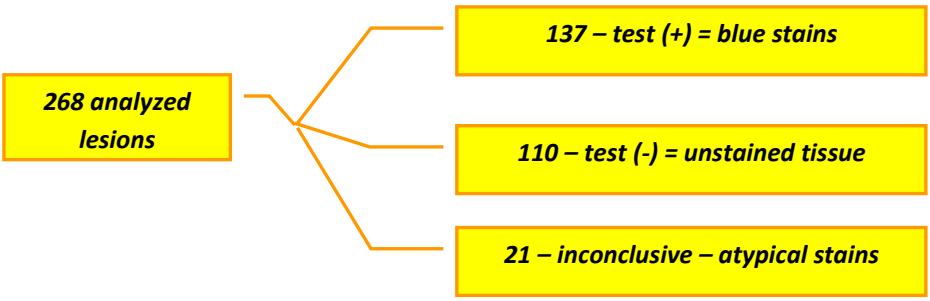
TABLE XI

Clinical diagnosis versus true diagnosis: Hyperplastic tumors

Clinical diagnosis			***True diagnosis***
Of 53 HYPERPLASTIC TUMOURS			*37 benign and 16 maligned*
Test	Stain	No. of patients	
(+)	Dark blue	6	Carcinoma *"in situ"*
	Light blue	2	Leukoplakia – false reaction (+)
(-)	Uncolored tissue	39	Benign lesions
			Malignant lesions – false reaction (-)

DISCUSSION

In conclusion, we can say that for the 268 analyzed lesions, the test results were:



From the total number of stains, some of them were *false*, as follows (tab. XII):

TABLE XII

Evaluation of the "blue stain" reaction

No of cases	Stain	No. of cases	Evaluation	%
137	stain (+) (for malignant and benign lesions)	96	Properly evaluated cases (+)	70%
		41	False cases (+)	21%
110	stain (-) (for inflammatory lesions, benign hyperplastic and malignant lesions)	94	Properly evaluated cases (-)	85%
		16	False cases (-)	12%
21	Atypical stain	3	Malignant lesions	
		18	Inflammatory lesions	

CONCLUSIONS

The dentist must diagnose and deal with precancerous lesions, and refer the patient, in useful time, to a specialized department of maxillofacial surgery (16, 17, 18, 19).

Toluidine blue staining must be considered a complementary method, useful to provide the dentist with an orientated diagnosis of pathogenic areas, that completes the physical examination.

If the false positive results do not provide the method a safety prerogative, we must then recognize its diagnostic role in locating abnormal areas on diffuse surfaces.

The simplicity of the method, the possibility of being used by any doctor, provides added value, positioning it among the techniques that should become usual in any dental office.

The main indirect form the dentist has to fight against cancer is dominated by prophylactic principles and consists in the competent practice of dental medicine.

The prophylactic principle must guide any procedure, dental or periodontal, prosthetic or surgical, for the removal of mechanical, chemical and thermal irritants from the oral cavity (20, 21).

All the above mentioned elements combined with oral septicity, on a carcinogenic background, turn into possible favoring factors for the development of oral cancer.

NEWS

INTRALEAFLET HEMORRHAGES ARE A COMMON FINDING IN SYMPTOMATIC AORTIC AND MITRAL VALVES

Worldwide, heart valve disease is an important clinical problem and responsible for a significant mortality and morbidity. Post inflammatory valvular disease, usually rheumatic of origin, is declining in the industrialized countries but still has a high incidence in developing countries, varying from 2.5 to 3.2 cases per 1,000. Traditionally, the pathogenesis of degenerative heart valve disease was thought to be the result of time-dependent "wear-and-tear" of the leaflets, which results in thickening of valve tissue due to fibrosis, calcification, and a low-grade inflammatory response. High rates of intraleaflet hemorrhage (ILH) have recently been reported in degenerative aortic valve disease. In that study, ILH was related to the severity of stenosis and preexistent valve tricuspid or congenitally bicuspid morphology. Hemorrhages in valve tissue, as noted by Akahori et al., could relate to "wear-and-tear" processes leading to small fissures, ruptures, or friction in the highly calcified valves. Alternatively, such hemorrhages could also relate to presence of microvessels since microvessels have been described in degenerative aortic valve tissue. Because nowadays, it is not known whether hemorrhages occur in degenerative aortic valves only or whether they can also be encountered in mitral valves and in other disease states such as rheumatic heart disease, the authors investigated the prevalence, extent, and age of ILH in a consecutive series of 105 surgically resected aortic and mitral valves. In addition, they investigated the presence of microvessels and the integrity of their vessel wall as a potential source of hemorrhages. Finally, all data were related to the pathological diagnosis of valve disease. The results showed, that the prevalence of ILH is very high in resected heart valves, both aortic and mitral valves presented an association of ILH with microvessels, microvascular leakage, and calcifications. The authors concluded that repetitive microvascular-leakage-related ILH may contribute to valve dysfunction on the (very) long term (Stam OCG, van Rijswijk JW, de Mol BAJM, van der Wal AC. Intraleaflet hemorrhages are a common finding in symptomatic aortic and mitral valves. *Cardiovascular Pathology* 2017, 30: 12-18).

FANCONI ANEMIA WITH CLEFT PALATE (Abstract): Fanconi anemia (FA) is a rare plurimalformative syndrome (1/350,000 newborns) presenting a large phenotypic heterogeneity, chromosomal instability and autosomal recessive inheritance (OMIM 227650). **Case presentation:** Male patient followed in the genetics service since infancy, till death. The child was referred for multiple congenital anomalies: bilateral aplasia of the radius and thumb, left kidney agenesis, cardiac malformation cleft palate, bilateral cryptorchidism, ear anomalies, which were associated, in time, with facial hyperpigmentation, anomalies of dental eruption, nasal septum deviation, and lumbar scoliosis. By the age of 10 years, he develop progressive pancytopenia, aplastic anemia. The diagnosis was completed by medulogram, immunogram, and karyotype. Treatment was primarily hematologic with substitution products, immunosuppressive, marrow stimulants, antibiotic therapy. Death occurred at age of 16 by infection and pulmonary hemorrhage occurred in severe pancytopenia. **Conclusions:** It is presented a rare case of Fanconi anemia customized by the clinical association with cleft palate and instructive clinical and evolutionary complexity. **Keywords**: FANCONI ANEMIA, CLEFT PALATE, CHROMOSOMAL INSTABILITY.

Fanconi anemia (OMIM 227650) is a rare plurimalformative syndrome presenting a large phenotypic heterogeneity, chromosomal instability and autosomal recessive inheritance. Recent determination of the carrier frequency gave an estimate of more than 1/200, with an expected prevalence at birth of at least 1/160,000. In certain populations, the carrier frequency is much higher, due to founder mutations. Until now, more than 2000 cases have been reported in the literature (1).

CASE PRESENTATION

A 16 year old boy, the first child in family, born at term, birth weight 2900 g; APGAR score 8/9. The parents are young and healthy and they are non-related. From past medical history: cleft palate (DP) operated at 1 year and; at 3 years old he was operated for cryptorchidism (orchiopexy). The boy was in evidence of Genetics Department from birth with plurimalformative syndrome (cleft palate, anomalies in size and shape of upper limbs).

Physical examination at 16 years old reveals: growth retardation, pallor; on the face presents ephelides and hyperpigmentation. Craniofacial dysmorphism (fig. 1): microcephaly, long face, microphthalmia,

epicanthus, anteverted ears, sharp nose, long neck. Oral cavity: palate with keloid scar after surgery. Upper limbs: bilateral, symmetrical shortening of the forearm (shortened to half of the normal size), forearms were a single long bone with bilateral thumb agenesis; lumbar scoliosis (fig. 2).

Fig. 1. Craniofacial dysmorphism, dental anomalies, keloid scar after surgery correction of cleft palate

Fig. 2. Size and shape anomalies of the upper limbs

Laboratory investigations showed: count blood cells (CBC): severe tricyto-penia; elevated levels of urea, creatinine and urine density. Bone marrow aspirate showed global marrow hypoplasia, marrow with fat tissue. Immuno-phenotyping revealed low number of NK cells; very low levels of lymphocytes B. In absolute value: lympho-penia with a marked decrease in lymfocyte B accompanied by a moderate decrease in NK cells. CD4/CD8 ratio is at the lower limit of normal. X-Ray: bilateral agenesis of the radius; lumbar scoliosis. Abdominal ultrasound: moderate hepatomegaly, absent left kidney and right kidney is hypoplastic and misaligned. Computer tomography (CT): absence of left kidney and pelvian position of the right kidney; dextroconvex lumbar scoliosis.

Interdisciplinary checkups: cardiologic exam including EKG: minor right arterial block. ENT exam: nasal septum deviation. Psychological evaluation: IQ 90.

Genetic investigations**:** We performed karyotype from peripheral blood: it was normal: 46, XY, but does not excluded the existence of chromosome breakages. Bone marrow karyotype showed a fragile site on the long arm of chromosome 12 band q14 (fig. 3).

The differential diagnosis include: the VATER/VACTERL association, Holt-Oram syndrome and TAR syndrome (thrombocytopenia and radial agenesis) mainly due to the radial abnormalities. Other conditions to be considered include the Blackfan -Diamond anemia (especially because of the hematological features), and other chromosomal instability syndromes such as the Bloom syndrome and the atax-ia-telangiectasia syndrome (2).

Treatment was as follows: *substitution*: red cell transfusions; *bone marrow stimula-*

tion: androgens, growth factors G-MSC (Neopogen); *immunosuppressant*: Prednisone, *symptomatic*: antibiotics, vitamins, Calcium, Magnesium, Aspacardin. Marrow transplant was not performed because no compatible donors.

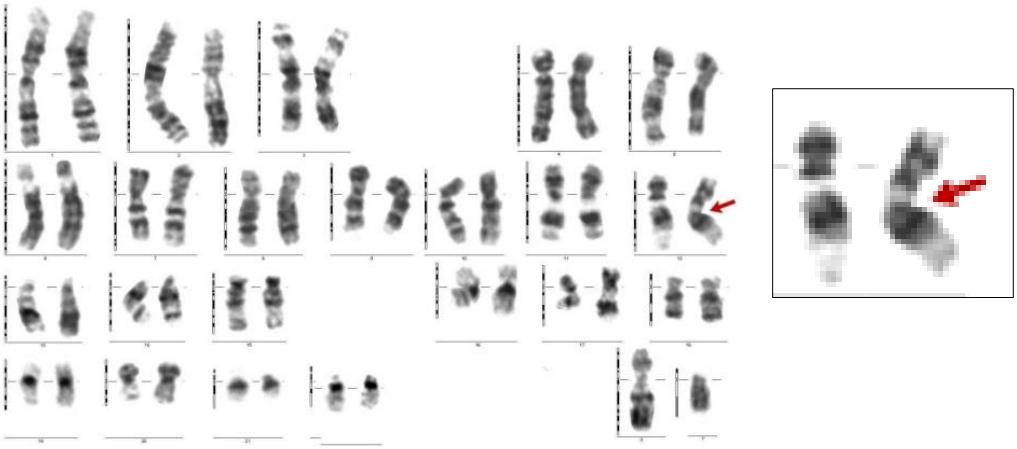

Fig. 3. Bone marrow karyotype

Evolution: at the age of 16 ½ years dies due to sepsis with multiple organ dysfunctions leading to severe pulmonary hemorrhage

DISCUSSION

Fanconi anemia, ataxia - telangiectasia and Bloom syndrome are hereditary disease resulting from mutations in genes that contribute to genome stability. Genomic instability promotes chromosomal breaks and rearrangements which is evidentiable by light microscopy examination of metaphase cells (3, 4, 5).

Today are identified 16 FA or FA-like genes: FANCA, FANCB, FANCC, FANCD1, FANCD2, FANCA, FANCF, FANCG, FANCA, FANCJ, FANCL, FANCM, FANCN, FANCP and RAD51C, XPF. Proteins codified by FA genes play a role in cellular response to oxidative stress, in cell cycle regulation, in DNA repair and chromosomal stability in tumor suppression. Majority patients have mutations in group A (60%), C (15%) or G (10%) of rest of 15% belongs to other subtypes (6, 7).

Most persons with Fanconi anemia develop malignancy, usually acute myeloid leukemia; 90% of patients develop bone marrow failure by the age of 40 years.

In 1927 Guido Fanconi described a family with three boys who had various birth defects and who subsequently developed pancytopenia (8). The syndrome is characterized by developmental defects, bone marrow failure and increased risk of cancer.

It is autosomal recessive inheritance in 99% of cases. Only FANCB gene is located on chromosome X such that its transmission will be recessive X linked (9).

The frequency in the general population is 1/350,000 births. FA occurs in all ethnic groups, but with a higher frequency (1/100 individuals) in Ashkenazi Jews and African population from South Africa (10, 11).

CONCLUSIONS

Fanconi anemia is a very heterogeneous condition clinically and patients can have a wide variety of abnormalities. Particularity of this presentation consists in associating with cleft palate, rarely described in the literature. The clinicians must recognize the considerable overlap of the FA phenotype with other malformation syndromes, and the need for applying a specific laboratory diagnostic test.

IN VITRO EVALUATION OF ANTIBACTERIAL EFFICACY OF PINEAPPLE EXTRACT (BROMELAIN) ON PERIODONTAL PATHOGENS

Periodontitis represents an inflammatory disease resulting in the destruction of periodontal tissues. Various treatment modalities (mechanical and surgical therapy) have been tried. Antimicrobial agents have been used as a monotherapy and as an adjunct with mechanical debridement. As antibacterial agents have been used different plant extracts. Pineapple extract (Bromelian) is one such agent. The aim of the study was to assess the antibacterial efficacy of Bromelain on aerobic and anaerobic periodontal microorganisms. Minimum inhibitory concentration (MIC) of Bromelain was tested on isolated strains of *Streptococcus mutans*, *Enterococcus fecalis*, *Aggregatibacter actinomycetemcomitans* (Aa), and *Porphyromonas gingivalis* (Pg) using serial dilution broth method. The results of the study showed that *S. mutans* showed sensitivity at the lowest concentration of 2 mg/ml as compared to *E fecalis* (31.25 mg/ml) while *P gingivalis* showed sensitivity at the lowest concentration of 4.15 mg/ml as compared to *Aggregatibacter actinomycetemcomitans* (16.6 mg/ml). In conclusion Bromelain exerts an antibacterial effect against potent periodontal pathogens; hence, it may be used as an antibacterial agent. To validate this result further trial has to be conducted. (Praveen NC, Rajesh A, Madan M, Chaurasia VR, Hiremath NV, Sharma AM. In vitro Evaluation of Antibacterial Efficacy of Pineapple Extract (Bromelain) on Periodontal Pathogens. *J Int Oral Health*, 2014; 6 (5) : 96-98).

*Corresponding author. E-mail: ciobotaru.marian@yahoo.com

SURGICAL MANAGEMENT OF PULMONARY HYDATIDOSIS IN CHILDREN (Abstract): Cystic echinococcosis (CE), the most common manifestation of the infestation with the larval form of the tapeworm Echinococcus granulosus, is a public health problem in endemic areas such as Moldavia. **Aim:** To retrospectively analyze pediatric patients who underwent surgery for pulmonary hydatid cyst over a 5-year period in order to assess the need for extensive lung resection. **Material and methods:** In the interval January 2007 – January 2012 30 pediatric patients with pulmonary hydatid cyst were surgically treated in the Department of Pediatric Surgery at the Iasi "St. Maria" Children's Hospital. We retrospectively reviewed the medical records of these patients **Results:** Patient age ranged from 3 to 14 years, and 21 patients (70%) came from rural areas. Respiratory symptoms (cough, chest pain, hemoptysis, fatigue, and dyspnea) were the main complaints. Chest radiography, computed tomography and serological tests made the diagnosis in all cases. The most common location of cystic lesions was the left lower lobe (40%). All patients were treated by enucleation and capitonnage of the residual cavity. Postoperative complications occurred in 5 cases (16.67%) and in one case (3.33%) a new hydatid cyst was diagnosed in the right lung after 2 years. **Conclusions:** The surgical treatment of choice was cyst enucleation with capitonnage, thus sparing the pulmonary parenchyma. Major lung resections are to be avoided in children when no severe lung destruction is detected. **Keywords*:*** PEDIATRIC PATIENTS, PULMONARY HYDATID DISEASE, ECHINOCOCCUS GRANULOSUS, ENUCLEATION, CAPITONNAGE

Cystic echinococcosis caused by *Echinococcus granulosus* is a very serious social, medical and public health problem in Romania with a yearly incidence of more than 3 cases/100.000 population in some geographical areas (1).

Echinococcosis is an anthropozoonosis with worldwide distribution caused by a small tapeworm of genus Echinococcus that can infect humans in its larval state. By passing through the intestinal wall into the portal circulation, the larva can locate itself into various organs of the intermediate host, the humans. Four types of *Echinococcus (E. Granulosus, E. Multilocularis, E. Vogeli, and E. Oligarthrus)* cause infection in humans. *Echinococcus granulosus* and *Echinococcus multilocularis* are the most common, causing cystic echinococcosis and alveolar echinococcosis, respec-

tively. Echinococcus Vogeli and E. oligarthrus cause polycystic echinococcosis and are less frequently associated with human infection (2, 3). Liver is the most commonly involved organ in more than 60% of cases, followed by lungs (10-40%), muscles, bones, peritoneum, kidneys, spleen and brain. Unlike in adults, in children the pulmonary tissue is the most commonly involved site and, unfortunately, does not have specific symptoms (4, 5). During the cystic stage the disease may remain asymptomatic for a long period of time. When symptoms occur, they are related to parasite size, location and load and caused by compression and complications (rupture, infection).

Preoperative diagnosis is based on a combination of methods such as history, physical examination, medical imaging procedures, laboratory and serological tests. Pulmonary hydatidosis is usually managed surgically or by combining surgery with administration of antiparasitic drugs. Medical treatment alone is rarely used and controversial (6, 7).

The aim of our paper was to retrospectively analyze the pediatric patients who underwent surgery for pulmonary hydatid disease over a 5-year period in order to assess the need for extensive lung resection surgery.

MATERIAL AND METHODS

The clinical records of 30 patients who underwent surgery for pulmonary hydatid disease in the interval January 2007 – January 2012 at the Department of Pediatric Surgery at St. Maria Children's Hospital, Iasi, Romania were analyzed. Hydatidosis was diagnosed based on physical findings, clinical symptoms, radiological examinations (chest X-ray and computed tomography), ultrasound, laboratory and serological test results (eosinophilia, enzyme-linked immunosorbent assay) and histopathological examination of surgical resection specimens.

Clinical, epidemiological, and laboratory data were analyzed together with surgical protocol details. IgG antibodies against *Echinococcus granulosus* were measured using commercially available enzyme-linked immunosorbent assay (ELISA) kit RIDASCREEN® Echinococcus IgG (produced by R-Biopharm AG, Landwehrstr. 54, D-64293 Darmstadt, Germany) that uses purified antigens bonded to a microwell plate. Antibodies in patient serum attach themselves to the antigens and are determined during the second phase of the test by using enzyme-labelled anti-human antibodies. The enzyme converts the colorless substrate to a blue end product, the final measurement being performed in a photometer.

Histopathological examination was performed on fragments collected during surgery, fixed by immersion in a 10% formaldehyde solution and embedded in paraffin blocks. Routine Hematoxylin and Eosin (H&E) staining was performed on sections cut from these blocks.

Surgical intervention was performed through posterolateral thoracotomy in most cases, and staged thoracotomy was the preferred surgical approach in bilateral cases. The cyst was surrounded by iodine-soaked gauze packs to prevent spillage and dissemination to surrounding structures. After neutralizing the cyst and aspirating its content, the intact germinative membrane was removed. The laminated layers were removed and then capitonnage of the residual cavity was performed. All patients received prophylaxis with Albendazole (15

mg/kg/day given orally in 2 divided doses) for 3–6 months postoperatively, in cycles consisting of 45 days of treatment alternating with 14 drug-free days). Patients were regularly followed-up postoperatively at 1 month after discharge and every 3 months thereafter for a period of 6–18 months. These visits included clinical examination, abdominal US, chest X-ray / CT if necessary, laboratory and serological tests in order to evaluate disease recurrence during the follow-up period.

RESULTS

The current study was performed in order to evaluate the clinical characteristics and surgical management of children with pulmonary hydatidosis. Of the 30 patients, 16 (53.33%) were males, 14 (46.67%) were females, and age ranged from 3 to 14 years (mean age 9.3 years). Most patients (21 cases - 70%) lived in rural areas and interacted daily with domestic animals, mainly dogs. Epidemiological investigation revealed that hydatidosis was previously diagnosed among family members of 8 (26.67%) patients. The patients presented for respiratory symptoms in 20 (66.67%) cases: cough (12 patients), chest pain (8 patients), hemoptysis (3 patients), fatigue (11 patients), and dyspnea (6 patients). A palpable abdominal mass was present in 2 (6.67%) patients having concomitant hepatic hydatid cysts. Lung hydatidosis was correctly identified on chest X-ray in 27 (90%) patients, 3 patients undergoing a computed tomography (CT) examination (fig. 1).

Laboratory test results showed eosinophilia in 21 (70%) patients, and erythrocyte sedimentation rate was elevated in 23 (76.67%) patients. Serological tests (ELISA kit RIDASCREEN® Echinococcus IgG) were performed in 12 patients and 10 (83.33%) of them were found positive, thus allowing an accurate preoperative diagnosis. The 2 patients with negative tests had uncomplicated cysts of 5.5 and 7.8 cm, respectively.

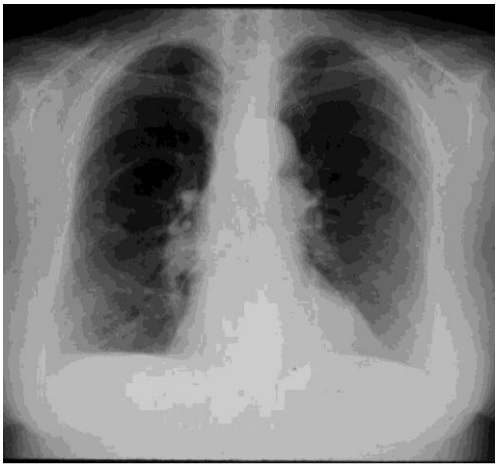

Fig. 1. Hydatid cyst located in the right lung

Cysts were located in the left lung in 14 (46.67%) patients, right lung in 12 (40%) patients, and 4 (13.33%) patients had bilateral cysts. The most frequent location was in the lower lobes, 21 (70%) patients (fig. 2).

Preoperative abdominal ultrasound was performed in all cases as part of the standard preoperative evaluation protocol, and identified concomitant liver hydatidosis in 6 (20%) patients, 2 of them with palpable masses. In 3 patients with hepato-pulmonary hydatidosis, the two locations were treated in a single operative time.

In 21 (70%) patients surgery was performed through an axillary thoracotomy; in 5 (16.67%) patients through an anterolateral thoracotomy; in 3 (10%) patients through a posterior thoracotomy; and only in one (3.33%) patient through an anterior thoracotomy. The cyst was intact in 18 (60%) patients. Bronchial fistulas were identified

in 13 (43.33%) patients and were repaired with absorbable material (Vicryl). In all cases the surgical technique consisted in enucleation and capitonnage of the residual cavity after previous inactivation with saline solution (30% NaCl) for 5-10 minutes.

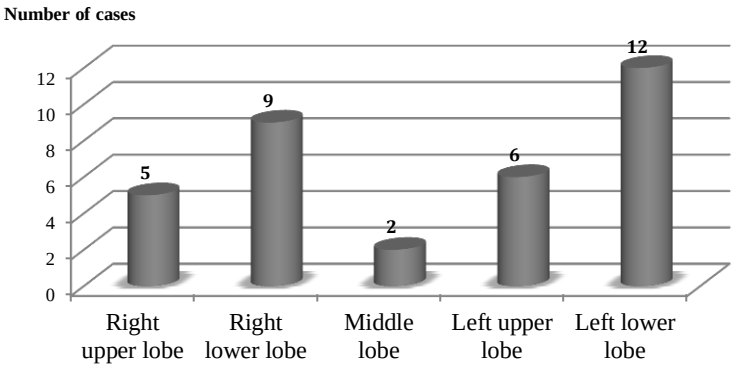

Fig. 2. Location of diagnosed hydatid cysts

Postoperative complications occurred in 5 (16.67%) patients: infection (abscess) of the residual cavity in 2 patients, treated conservatively with antibiotics; pneumothorax due to reopening of bronchial fistula in 2 (40%) patients, and atelectasis of the left lung in 1 patient. No patient required reoperation, but bronchoscopy with mucus plug aspiration was required in the patient with left lung atelectasis. Hydatidosis recurrence was recorded in one patient 2 years after the first intervention; the new hydatid cyst was located in the same lung (right), and reoperation was needed despite medical treatment with Albendazole one year after the first surgery.

Mean hospital stay was 12.7 days (range 10-25 days) with a 0% mortality rate. Mean follow-up period was 2.9 years (2 months to 5 years) by chest X-ray at a 6 months interval in the first postoperative year and then annually.

DISCUSSION

As previous studies stated, 10-20% of pulmonary hydatidosis cases are diagnosed during childhood, the statement that in children the lung is the most commonly affected organ by cystic echinococcosis being controversial (8, 9).

As in other locations, pulmonary hydatid cyst may be asymptomatic for a long period of time and diagnosed incidentally, or manifest itself only when voluminous or complicated. Pulmonary hydatidosis in children becomes symptomatic more easily compared to liver hydatidosis, due to the compressible nature of lung parenchyma, its higher vascularity and lower negative pressure (10). In endemic areas, general practitioners as well as specialist doctors (pediatrician, pediatric surgeon, general or thoracic surgeon), should be aware and suspect hydatidosis in all cases at risk (rural area, animal contact, eosinophilia, non-specific respiratory or digestive symptoms, palpable abdominal mass, acute abdomen) and rule out this disease. Chest radiography is a simple yet essential method in diagnosing lung hydatidosis as well as an ideal tool for localization and surgical planning (11). In the present study, pulmonary involve-

ment appears to be slightly more prevalent in boys (53.33%), possibly because they get into contact with infected materials more often than girls. As in order studies, pulmonary infestation is encountered more frequently in children older than 9 years (mean 9.3 years) (12).

The most frequently encountered symptoms in patients with pulmonary hydatidosis are determined by the mass effect exerted on surrounding tissues, rupture or supra-infection of the cyst causing pneumothorax, pleural effusion, or empyema. In the present study, patients were admitted with nonspecific respiratory symptoms in 2/3 of cases (20 patients – 66.67%). Serological tests like IgG ELISA can be used for diagnosing hydatidosis, but they should always be doubled by other methods as false negative results occur in uncomplicated lung cysts as it was noted in our study. In the present study, hydatid cysts were most frequently located in the lower lobes (21 patients – 70%), similar results with the ones reported in the literature (2, 5, 6).

Currently, there is no standardized treatment for pulmonary hydatidosis, the aim of any treatment being parasite eradication and recurrence prevention, while the additional aims of surgical treatment are prevention of intraoperative rupture and obliteration of the residual cavity (capitonnage). Surgical options in pulmonary hydatidosis are represented by enucleation with or without capitonnage, wedge resection, lobectomy and pneum-ectomy.

The aim of the surgical treatment is complete excision of the cyst with maximum preservation of the lung tissue. In pediatric patients there is no need to perform major lung resections like lobectomy or pneumectomy as adjacent lung parenchyma destruction is rare. In peripherally located cysts, wedge resection may be performed with minor or no sequels. In our study group, all patients were treated by enucleation with capitonnage of residual cavity. The low rate of complications, conservatively manageable, supports this type of surgical approach. Large pulmonary resections may be more deleterious to the patient and cause future morbidity.

Initially, concomitant pulmonary and hepatic hydatidosis was treated in two-stages (3 patients), enucleation of the pulmonary cyst being the first intervention due to the high risk of rupture during abdominal surgery. With the progress of anesthetic methods and better postoperative management, which allows early intensive physical therapy, hepatic and pulmonary hydatidosis have been addressed in a single surgical time (3 cases).

Axillary thoracotomy was the preferred surgical approach in our study group as it allows entering the chest only by sectioning intercostal muscles, thus producing less postoperative pain and facilitating an early recovery, crucial in pediatric surgery. At the same time, aesthetic results are better, as the scar is located in an inconspicuous area and there are no long-term sequels like scoliosis. Thoracoscopic procedures and percutaneous drainage have been tried by several authors but they are not worldwide accepted due to the high risk of dissemination and anaphylactic reaction (13).

In our study postoperative recovery was favored by an early started respiratory physiotherapy.

The use of antiparasitic drugs like Mebendazole and Albendazole has been shown in several studies to be helpful in preventing relapses (14). Their efficacy when used as a single primary treatment is debatable, as the drug has to reach the germinal layer, a process achievable only in

small cysts with thin walls. In our study, Albendazole was prescribed in 3 high-risk patients (bronchial fistulas), one of them being re-operated after two years for a new hydatid cyst in the same lung. However, due to insufficient availability of this resource and limited compliance to treatment in rural areas, a complete therapy cannot be ensured in all cases.

CONCLUSIONS

The preferred surgical treatment of pulmonary hydatidosis in our study group was cyst enucleation and capitonnage of the residual cavity, thus sparing pulmonary parenchyma. Major lung resections were avoided, as severe lung destruction is rare in children. Surgical treatment should be completed by administration of antiparasitic drugs in high-risk patients, when hydatidosis may disseminate by fistulas or secondary to perioperative complications. Pulmonary hydatidosis should be carefully considered in the differential diagnosis of respiratory or digestive symptoms in endemic areas.

EPIDEMIOLOGY OF B/C VIRUS INFECTION HEPATITIS IN THE NORTHERN MOLDAVIAN CORRECTIONAL FACILITIES-RISK FACTORS (Abstract). **Aim.** To identify the specific risk factors for chronic hepatitis B/C virus infections in the correctional system in Moldova (Romania). **Material and methods.** The study included 533 subjects imprisoned in three correctional facilities located in the Northern region of Moldova. The subjects were divided into 2 groups: HBV/HBC group – 108; Control group – 425. **Results**. The risk factor for transfusion-contracted HBV/HCV was 3.73; the empirical treatment of the HBV/HBC group resulted in a relative infection risk of 2.62; syringe sharing in the HBV/HBC group accounted for a risk factor of over 4 (OR=4.33); tattooing induced a relative risk factor of 1.25, and piercing was a risk factor of approximately 2 (OR=1.97); sharing personal care items represented a risk factor of over 2 (OR=2.02). Injection drugs induced a relative risk of over 4 (OR=4.33). In the HBV/HCV group, self-aggression represented a risk factor of 1.65. **Conclusions** Prison environment, by its specific and nonspecific contamination modalities (shared with the rest of the population but more common) causes that inmates to be 2-4 times more exposed to hepatitis B/C infection. **Key words:** B/C HEPATIC VIRUS, IMPRISONED POPULATION, RISK FACTORS, EPIDEMIOLOGY

This study on inmate specific diseases and prevention possibilities reflects the epidemiological permanent concern for the needs of people deprived of their freedom. The expected impact is the reduction of morbidity and mortality among *people deprived of their freedom* (PDF) under conditions specific to the correctional system and in correlation to the trend of these indicators in the general population. The aim of this study was to identify the specific risk factors for chronic hepatitis in the correctional facilities located in North Moldavia, the seroprevalence among the studied population, and their correlation with national and international statistical data.

MATERIAL AND METHODS

The informed consent was obtained from every PDF included in the study. An epidemiological questionnaire was used to

determine the risk factors. The research was performed in the medical offices of correctional facilities in Northern Moldavia and included new inmates but also inmates sentenced to more than 5 years already in prison for some time who met the ***se****lection criteria.* The selection criteria were: age over 18; decision-making abilities; newly admitted inmates or transferred to serve their sentence; freely-expressed consent. *Exclusion criteria:* age under 18; no decision-making ability; pregnancy. 533 inmates were enrolled in this study conducted in the interval October 2010– October 2012 in three correctional facilities in Northern Moldavia. 479 (89.9%) inmates in Iaşi correctional facility and 49 (4.5%) inmates in Tg. Ocna correctional facility were subjected to epidemiological screening. Also included in the study were 30 female inmates in Bacau correctional facility. The sampling methods demonstrated that compared to the total number of inmates in Romania (n=31,720), with a sampling error of ± 4.2%, the study group was representative. Depending on the presence or absence of hepatitis B/C virus infection, the study group was divided into 2 subgroups: HBV/HCV – 108 subjects found positive; Controls – 425 subjects found negative for hepatitis B/C virus.

The study was transversal, presenting the situation at one specific point in time in study population. In order to measure the intensity of the associations between the monitored parameters we used as analytical technique the estimation of the relative risk (OR). The advantages of this type of study are: easy to perform, moderately expensive, performed in a given population easy to approach and observe, and is reproducible. This last advantage opens the perspective of using the method as a working tool for this type of population, with the aim of targeting the population to be tested and possibly diagnosed with hepatitis virus infection. To assess the specificity of the risk factors the Receiver Operating Characteristic (ROC) curve was generated by minimizing the distance between the ideal sensitivity (100%) and the 1-specificity point (0%). The data were uploaded and processed with the help of the statistical functions of *SPSS 13.0* software.

RESULTS

Medical Risk factors. 42.6% of the subjects in the HBV/HCV group and 34.4% of those in the control group had surgical interventions (p=0.139). In both groups, approximately 8% of the subjects had frequent hospital admissions, without significant differences in frequency distribution (p=0.882). The percentage of subjects who received blood transfusions was significantly higher in the HBV/HCV group (p=0.001) as compared to the control group (16.7% *vs.* 4.5%). Empirical treatment was used significantly more frequently in the HBV/HCV group (11.1%) as compared to controls (4.2%) (p=0.011). 36.1% of the HBV/HCV subjects and 27.1% of the controls had dental treatments the frequency distributions being statistically insignificant (p=0.083). Accident-related risk factors were found in 15.7% of the subjects in the HBV/HCV and 1.3% of the controls (p=0.273) (tab.I).

The ROC curve highlights that blood transfusions and use of empirical treatment were the main risk factors for hepatitis B or C virus infection (fig.1).

TABLE I

Risk factors by study subgroups

Risk factor	HBV/HCV (n=108)		Controls Lot (n=425)		Significance		OR	CI 95%
	n	%	n	%	χ^2	p		
Medical risk factors								
Surgical interventions	46	42.6	146	34.4	2.19	0.139	1.24	0.96÷1.60
Frequent hospital admissions	9	8.3	36	8.5	0.02	0.882	0.98	0.49÷1.98
Blood transfusions	18	16.7	19	4.5	17.99	**0.001**	3.73	2.03÷6.86
Empirical treatment	12	11.1	18	4.2	6.39	**0.011**	2.62	1.30÷5.27
Dental treatment	39	36.1	115	27.1	3.01	0.083	1.33	0.99÷1.79
Accident	17	15.7	48	11.3	1.20	0.273	1.39	0.84÷2.32
Non-Medical Risk Factors								
Syringe sharing	11	10.2	10	2.4	11.97	**0.001**	4.33	1.89÷9.93
Cosmetic treatment	9	8.3	30	7.1	0.06	0.804	1.18	0.58÷2.41
Tattoos	70	64.8	220	51.8	5.40	**0.020**	1.25	1.06÷1.48
Piercing	49	45.4	98	23.1	20.36	**0.001**	1.97	1.50÷2.58
Sharing personal care items	40	37.0	78	18.4	16.37	**0.001**	2.02	1.47÷2.77
Toxic substances consumption								
Daily alcohol intake	70	64.8	216	50.8	6.23	**0.013**	1.28	1.08÷1.51
Injection drug	11	10.2	10	2.4	11.97	**0.001**	4.33	1.89÷9.93
Cocaine	8	7.4	18	4,.2	1.25	0.264	1.75	0.78÷3.91
Pain killers	32	29.6	82	19.3	4.87	**0.027**	1.54	1.08÷2.18
Tuberculosis medication	11	10.2	46	10.8	0.04	0.986	0.94	0.50÷1.75
Hepatotoxic medication	19	17.6	66	15.5	0.14	0.707	1.13	0.71÷1.80
Accidental poisoning	13	12.0	14	3.3	11.93	**0.001**	3.65	1.77÷7.54
Psychiatric treatment	23	21.3	85	20.0	0.03	0.869	1.06	0.71÷1.60
Aggression								
Sexual	2	1.9	12	2.9	0.05	0.820	0.66	0.15÷2.89
Physical	20	18.5	68	16.0	0.23	0.628	1.16	0.74÷1.82
Self-aggression	42	38.9	100	23.5	9.62	0.002	1.65	1.23÷2.21

Non-medical risk factors. The proportion of HBV/HCV subjects sharing syringes was significantly greater (p=0.001) as compared to controls (10.2% *vs.* 2.4%). The frequency distribution of the subjects who had cosmetic treatment was reduced in both study groups (8.3% *vs.* 7.1%), without statistically significant percentage differences (p=0.804). The frequency of tattoos was high in both study groups, 51.8% in the control group

and 64.8% in the HBV/HCV group, but the proportion of HBV/HCV subjects was significantly higher (p=0.02). Significantly more HBV/HCV subjects had piercing (45.4% *vs.* 23.1%) (p=0.001). 37% of the HBV/HCV subjects and only 18.4% of the controls shared personal care items, statistically significant percentage differences (p=0.001). The ROC curve showed that sharing syringes and personal care items were the main risk factors for hepatitis B or C virus infection (fig. 1).

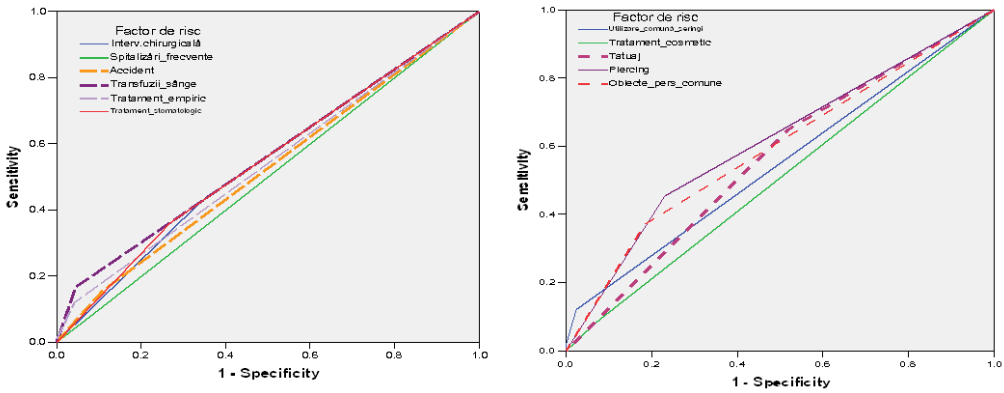

Fig. 1. The specificity of medical and non-medical risk factors

Only 28.6% of drug users had no prior criminal history, the remaining 71.4% having previously served sentences with deprivation of freedom. Of all tattooed subjects only 23.5 % had no prior criminal history, getting tattoos when free, possibly in tattoo parlors, and 76.5% got tattoos in the correctional facility, in the absence of the equipment and access to sterile tattoo instruments. Moreover, there were inmates who got tattoos while serving their twelfth sentence with deprivation of freedom, although they had not done it while serving previous sentences. Nevertheless, the majority of inmates get tattoos when serving their first sentence in a correctional facility and report current tattoos upon subsequent imprisonments (fig. 2).

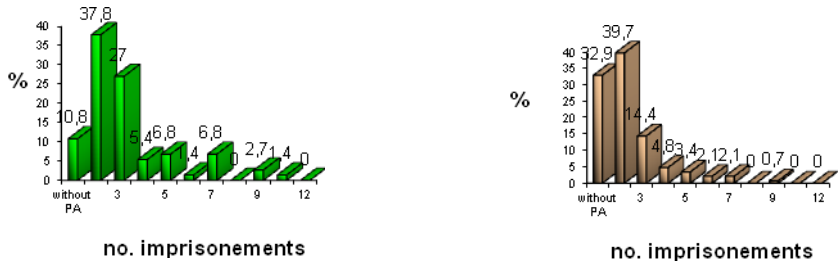

Fig. 2. Distribution of subjects with tattoos and piercings according to the number of imprisonments

As in the case of tattoos, the great majority of inmates start wearing piercings at the beginning of their „imprisonment career" (fig. 3).

Fig. 3. Distribution of subjects who commonly use personal objects, according to the number of imprisonments

Intake of toxic substances. 64.8% of the subjects in the HBV/HCV group and 50.8% of the controls reported daily alcohol intake, the percentage difference being statistically significant (p=0.013). The daily alcohol intake was of over 60 g in 62.9% of the HBV/HCV subjects and 53.7% of the controls. The frequency of subjects who use injection drugs was significantly higher in the HBV group (10.2%) as compared to the control group (2.4%) (p=0.001). Declaratively, crack cocaine sniffing was rare in both study groups (7.4% *vs.* 4.2%), the difference not being statistically significant (p=0.264). In the study series we noticed a significantly increased frequency (p=0.027) of the use of pain killers in the HBV/HCV group (29.6%) compared to the control group (19.3%). The frequency of tuberculostatic drugs use showed no significant differences between the study groups (p=0.986), being of approximately 10-11%. There were no significant differences in the intake of hepatotoxic substances between the study groups (p=0.707): 17.6% in the HBV/HCC group and 15.5% in the controls. Significantly more HBV/HCV subjects (p=0.001) experienced accidental poisoning than controls (12% *vs.* 3.3%). In both study groups approximately 20-21% of the inmates underwent psychiatric treatment. ROC curve identified daily alcohol intake of and pain killers as the main risk factors (fig. 4).

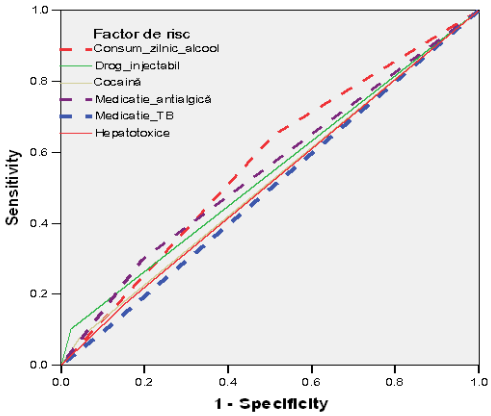

Fig. 4. Specificity of toxic substances intake as risk factors

62.8 % of inmates who drank alcohol daily had prior criminal history (fig 5).

Fig. 5. Distribution of subjects who drank alcohol daily according to the number of imprisonments

The distribution of subjects shows that 57.9 % of injection drug users and 73.1% of those who sniffed cocaine had previous criminal history.

59 % of those who chronically take pain killers, 69 % of the inmates who reported treatment with tuberculostatic drugs and 65 % of those who take psychiatric medication have been imprisoned before (fig. 7).

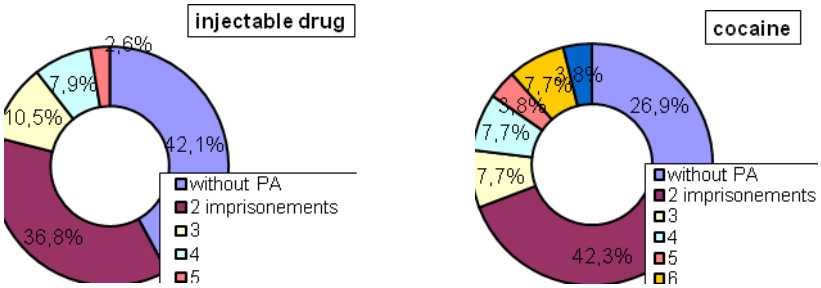

Fig. 6. Distribution of injection drug users and crack cocaine sniffers according to the number of imprisonments

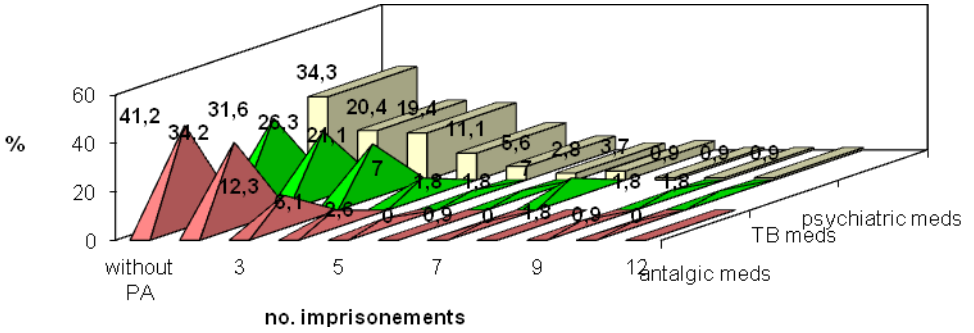

Fig. 7. Distribution of subjects by medication types according to the number of imprisonments

Other risk factors – Aggressions. 1.9% of the subjects in the HBV/HCC group and 2.8% of the controls reported they had been sexually abused, differences statistically insignificant (p=0.820). Physical aggression was reported by 18.5% of the HBV/HCV subjects and 16% of the controls, without significant difference in frequency between the study groups (p=0.628). Self-aggression was significantly more common in the HBV/HCV group (38.9%) as compared to the control group (23.5%) (p=0.002).

According to aggression type, the ROC curve confirmed that self-aggression is a main risk factor (fig. 8).

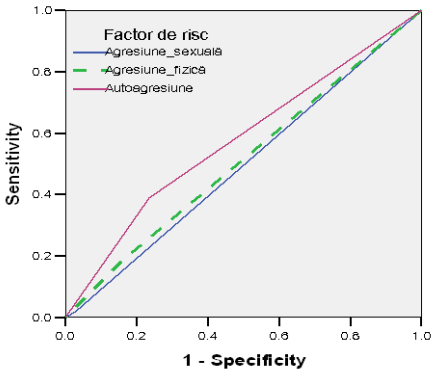

Fig. 8. Specificity of aggression as a risk factor

Physical aggression was present in 57.1% (57.1% *vs.* 42.9%) of the inmates

with criminal history, sexual aggression in 73% (73% *vs.* 27%), whereas self-aggression was more frequent in inmates who had been in prison before (58.5% *vs.* 41.5%).

DISCUSSION

Chronic liver infection is an important health problem worldwide, the strategies to prevent infections, by delivering safe blood products to injection drug users are essential and applied in most countries starting with 2000 (1,2). Many inmates are not aware that they carry the virus and are identified in the chronic stage of liver disease or in the phases of complications related to over-infection or malignant change (3). In Romania there are few nationwide evaluations of the risk of hepatitis B and C virus infection, and in the correctional system only the new acute cases reported to the Public Health Authority without identifying with certainty the infection source because of inmates' lack of trust in the health system are known. If worldwide vaccinating inmates against hepatitis B manages to keep under control this form of hepatitis, in Romania, because of the precarious situation of the public health system this prophylactic measure does not exist (4). Aggression and self-aggression are risk factors specific to correctional facilities, committed for obtaining material and non-material goods, but also a hierarchical positioning among the inmates. Many times this is a form of protest against detention conditions but also a way to emotionally touch or blackmail the staff. Self-harm is done with hand-made, improvised, and shared objects: self-made knives, needles or nails made from mattress springs, iron in the structure of furniture pieces, metal door and window parts and even glass pieces. The contamination risk is extended not only to the inmates sharing this object, but also to prisoner escort officers and security staff and even to the medical staff if aggressed by inmates or upon periodical checks of inmate personal property – accidental piercing. Minor surgical procedures as well as dental treatments represent a real epidemiological danger because they are numerous and are performed by a small number of doctors and nurses. Tattooing is another common way inmates are getting hepatitis B or C. It is a common practice among inmates, 76% of the tattooed individuals obtained it while in a correctional facility, of whom 37.8% during serving their first sentence. Tattoos are made with non-sterile, self-made and shared objects. In correctional facilities piercing is also empirically-performed, the earrings and even the piercing needle being self-made (5, 6, 7).

CONCLUSIONS

Blood transfusions account for a risk factor of 3.73; the empirical treatment induced in the HBV/HCV group a relative risk of infection of 2.62.

Sharing syringes was for the HBV/HCV group a risk factor of over 4 (OR=4.33); tattooing induced a relative risk of 1.25 in the HBV/HCV group and piercing was a risk factor of approximately 2 (OR=1.97); sharing personal care items represented a risk factor of over 2 (OR=2.02). Injection drugs induced a relative risk of over 4 (OR=4.33). In the HBV/HCV group, self-harm represented a risk factor of 1.65. Even though the frequency of crack cocaine sniffing in the HBV/HCV group was not significantly higher as compared to the

control group (7.4% *vs.* 4.2%), the calculated relative risk of infection with hepatic viruses was of 1.75 in the HBV/HCV group.

Accidental poisoning caused a relative risk of OR=3.65 in the HBV/HCV group. Psychiatric treatments had a statistically insignificant study group distribution (p=0.869).

For subjects in the HBV/HCV group self-harm was a 1.65 times stronger risk factor as compared to the control group.

EFLECTANCE CONFOCAL MICROSCOPY FOR MEASURING *DEMODEX* DENSITY

A study by Turgut Erdemir *et al* compared the effectiveness of standardized skin surface biopsy (SSSB) and the reflectance confocal microscopy (RCM) for measuring the *Demodex* mite density. Forty-seven healthy controls and 48 patients with pityriasis folliculorum, papulopustulary rosecea and erythema-telengiectatic rosacea were enrolled in the study. The area with the most intense erythema on the right cheek was selected for imaging with RCM (VivaScope 3000) and SSSB. RCM identified demodicosis in 48 patients (100%), while 42 patients (85.7%) showed high *Demodex* density (> 5 mites/cm2) with SSSB. The mean Demodex density measured with RCM was significantly higher than SSSB. The results demonstrate that reflectance confocal microscopy is a fast and noninvasive method, superior to SSSB, for *Demodex* mite detection (Turgut Erdemir A, Gurel MS, Koku Aksu *et al*. Reflectance confocal microscopy vs. standardized skin surface biopsy for measuring the density of *Demodex* mites. *Skin Res Technol*. 2014. doi: 10.1111/srt.12137).

SUBACUTE FUNGAL ENDOCARDITIS DUE TO *ACREMONIUM SPP*: A CASE STUDY AND REVIEW OF THE LITERATURE

3. Institute of Cardiovascular Diseases Iasi

SUBACUTE FUNGAL ENDOCARDITIS DUE TO *ACREMONIUM SPP*: A CASE STUDY AND REVIEW OF THE LITERATURE (Abstract): A 52 years old patient is hospitalized in June 2007 in the Cardiology Clinic of Cardiovascular Diseases Medical Institute in Iasi with suspected subacute infectious endocarditis. Echocardiography shows mobile vegetation on the pulmonary valve. *Acremonium* spp is isolated from blood cultures after 2 weeks of incubation. The patient was treated with fluconazole, but died after 3 months due to renal failure.
Keywords: SUBACUTE FUNGAL ENDOCARDITIS, *ACREMONIUM SPP*, ECHOCARDIOGRAPHY.

Acremonium species are widespread in soil and are recognized as plant and insect pathogens rarely cited in humans and other mammals infections. Human infections typically occur after penetrating skin injuries, so infections are mostly in the extremities, especially mycetomas after traumatic inoculations (1).

Other sites of infection include eye, lung and gastrointestinal tract colonization, osteomyelitis, sinusitis, arthritis and peritonitis. Disseminated infections (meningitis, endocarditis, brain abscess) were rarely reported before, especially after valve replacement, dialysis, transplantation and hematologic malignancies in patients with other types of cancer (2, 3, 4, 5). In recent years the number of infections caused by *Acremonium* spp increased considerably due to predisposing conditions: invasive medical techniques, new impaired immune system conditions (6).

In what follows we will describe a case of native valve endocarditis in an immunocompetent patient.

CASE REPORT

Patient BV of 51 years without cardiopulmonary history, was admitted the Tecuci Hospital in 29.06.2007 with febrile syndrome, chest pain, cough with mucopurulent expectoration, dyspnea. The patient was diagnosed with lobar pneumonia; septic status and congestive heart failure according to NYHA class III. He received treatment with ampicillin + gentamicin, but the fever and congestive heart failure phenomena persisted. The patient was transferred to the hospital in Galati where a transthoracic echocardiography (TTE) was

performed. The echocardiography revealed:

- Increasing right heart cavities;
- Moderate pulmonary hypertension, dilatation of the aortic ring with second degree aortic insufficiency.

For furher investigation the patient was transferred to the Departament of Medical Cardiology of our institute on 2.08.2007. The patient underwent CT examination with the following results:

- On right lower lung: echodense formation, non-homogeneous, with invasive character;
- Pleural effusion in average quantity.

These elements raise the suspicion of lung cancer.

Because of persistent febrile syndrome and the congestive heart failure, the patient is still investigated for suspected endocarditis, which is why he performed a transoesophageal echocardiography (TEE) highlighting a new set of issues:

- Aortic valve: mild calcification;
- Mitral valve: normal morphology, first degree mitral insufficiency;
- Pulmonary valve: destroyed by two oscillating vegetations of 2.3 cm and 2.4 cm, third degree pulmonary valve insufficiency;
- Tricuspid valve: abnormal, modified, possible vegetation on the septal cusp, third degree tricuspid valve insufficiency.

Four sets of blood cultures were drawn (each set included one aerobic and one anaerobic bottle). Blood cultures remain negative at 9 days, but because of suspected endocarditis, we prolonged the cultures up to 3 weeks.

Early consultation with a cardiac surgeon was recommended in order to determine the best therapeutic approach. The cardiovascular surgeon decided that the surgical intervention could be postponed to allow the antibiotic treatment to take effect and avoid contamination of the prosthesis.

The patient was discharged with instructions to make fibrobronchoscopy and admission to Infectious Diseases Hospital for treatment: vancomycin 1g x 2/day + gentamicin 80mg x 2/day for 1 week and nistatin for 2 weeks.

After 14 days of incubation *Acremonium* spp was isolated from all 4 cultures and the patient received treatment with fluconazole 400mg x 2 / day intravenously for 30 days. At the beginning of treatment the patient had a second episode of pulmonary embolism.

On 10.12.2007 the patient returned for a review, in a state of afebrility but symptomatic for fatigue and dyspnea on moderate physical effort. TEE shows non oscillating vegetations on pulmonary and tricuspid valves. Blood cultures collected at that moment were negative.

In December 2007 the patient was admitted for a new episode of endocarditis, initially interpreted as acute renal failure, but blood cultures were positive for methicillin-sensitive *Staphylococcus aureus*. He received treatment with oxacillin + ciprofloxacin, but renal function (oliguria <0.5 L / day and creatinine 4 mg %) cannot be improved and the patient dies.

DISCUSSION

We found very few (only 10 studies) reporting endocarditis caused by *Acremonium* spp (7, 8, 9, 10, 11), most of them prosthetic valve endocarditis (mechanical prosthesis St. Jude no. 27, infective endocarditis on pacemaker, dura mater prosthesis). Infection in our patient affected native valve (pulmonary valve and tricuspid valve). We could not identify the gate of entry (mycetoma or trauma history). Note

that the patient was a professional driver and had a flaky lesion on the right foot, but no mycological examination was performed at the level of the injury.

Infection developed slowly over 2 months with prolonged febrile syndrome and pulmonary embolism, due to the vegetation being located in the right heart. Diagnosis of infective endocarditis was made based on TEE, blood cultures were positive after 10 days of incubation; identification of the fungus was performed after another 4 days.

Acremonium gender diagnosis is quite easy to make based on the microscopic and culture characteristics: growing moderately fast (but not more than 3 cm in 10 days), yellowish-white colonies, fasciculate (spiky), glabrous or moist. Conidiogenous cells solitary, slender (ca, 2µm wide), mostly unbranched, awl (needle-shaped) phialides. Conidia one celled, straight or curved, in slimy masses (fig.1, 2).

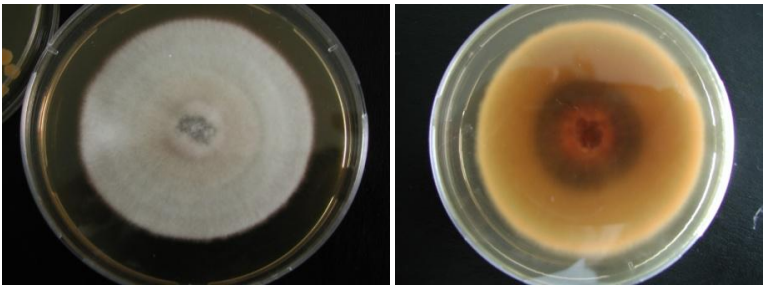

Fig 1. Appearance of culture on Sabouraud medium after 7 days of incubation (obverse and reverse)

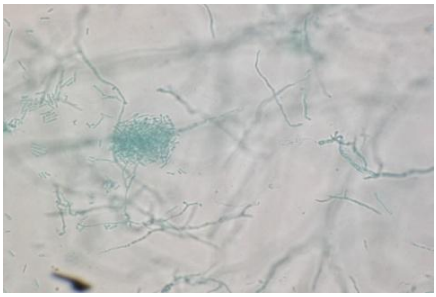

Fig. 2. Microscopic Appearance - wet preparation, 400

Acremonium species are morphologically very similar so that their identification is extremely difficult; therefore in most clinical cases etiologic agents are confused with *Acremonium* spp. This is the main reason why the actual incidence of *Acremonium* species is still unknown.

Identification of clinical isolates of *Acremonium* spp based on modern molecular methods are difficult to perform mainly due the absence of a public database of reference nucleotide sequences required for comparison for great genetic diversity of *Acremonium* spp, means that it suffers from a yearly taxonomic reshuffle. (13). We have sent our isolate to a reference laboratory, but it could not be identified to species level.

According to CLSI (M38-A2) (Clinical Laboratory Standard Institute) antifungal susceptibility should be made by the plate dilution method, a method that could not be done in our laboratory. Although, the literature data (13, 14) describes a decreased susceptibility to fluconazole (and imidazoles in general) in isolates of *Acremonium* spp. The literature generally recommends the use of amphotericin B. Because the lack of availability of this drug, the patient received i.v. fluconazole 400 mg x 2/daily for 30 days. Following this treatment, the clinical condition improved and the trans-esophageal echocardiography performed for control showed decreasing vegetation.

CONCLUSION

Acremonium spp can cause native valve endocarditis in immunocompetent persons. Fluconazole given intravenously for 30 days, two weeks more than the short-term therapy described in the literature (14), may improve the clinical condition of the patient with endocarditis.

THE INFLUENCE OF ASOCIATING GREAT PHYSICAL EFFORT WITH NIGHT SHIFTS ON HYPERTENSIVE PATIENTS

S. Morariu[1], Brânduşa Constantin[2]
University "Vasile Goldis"- Arad
1. Faculty of Medicine
University of Medicine and Pharmacy "Grigore T. Popa"- Iasi

2. Discipline of Occupational Medicine

THE INFLUENCE OF ASOCIATING GREAT PHYSICAL EFFORT WITH NIGHT SHIFTS ON HYPERTENSIVE PATIENTS (Abstract): A great physical effort associated with work during night shifts can lead to negative effects on the worker's health. **The aim** of our study is to evaluate the risk of associating great physical effort with night shifts in hypertensive patients. **Material and methods**: We have studied 2 groups of hypertensive patients, each group being consisted of 20 male patients, age 30 to 50, that have been diagnosed with mild hypertension during the periodical medical exam, group I being consisted of subjects that performed great physical effort, and their work program implied night shifts. Group II consisted of workers that performed work that implied mild effort during day shifts. **Results and discussions**: At the end of the 2 year study period, 8 patients from group I (great physical effort associated with night shifts) developed a severe increase in blood pressure (beyond 160/100 mmHg), as well as an increase in basal cardiac frequency, whilst only one patient from group II presented such modifications. **Conclusions**: Night shift work associated with great physical effort can lead to a significant rise in blood pressure and heart rate, all the more if the subject suffers from hypertension thus predisposing the patients to coronary events. **Keywords**: WORK, NIGHT SHIFTS, HYPERTENSION, OCCUPATIONAL HEALTH

It is well known that great physical effort, performed in uncontrolled situations can lead to an increase in blood pressure and heart rate (1). Work during night shifts disrupts the circadian rhythm (2). Associating great physical effort with night shifts can have a negative impact on worker's health.

The aim of our study is to evaluate the risk of associating great physical effort with night shifts in hypertensive patients.

MATERIAL AND METHODS

We have studied 2 groups of hypertensive patients, each group being consisted of 20 male patients, age 30 to 50, that have been diagnosed with mild hypertension during the periodical medical exam.

Group I consisted of subjects that performed great physical effort and their work program implied shifts, including night shifts.

Group II consisted of workers that performed work that implied mild effort during day shifts.

The subjects of the 2 groups were monitored by Holter (blood pressure and heart

rate). All subjects had the following blood tests taken at the debut and end of our study: urea, creatinine, uric acid, glycemia, cholesterol and triglycerides. The following types of patients were excluded from our study: patients with behavioral risk factors (coffee, alcohol, smoking, excessive salt intake), as well as hypertensive patients undergoing medical treatment.

The subjects of the 2 groups were monitored for a period of 2 years, having their blood pressure, heart rate and blood tests periodically determined.

RESULTS

At the end of the 2 year study period, 8 patients from group I (great physical effort associated with night shifts) developed a severe increase in blood pressure (beyond 160/100 mmHg), as well as an increase in basal cardiac frequency. These persons necessitated immediate implementation of medical treatment, as well as modifying their program into day shifts (fig. 1).

Only one patient from group II, implying mild physical effort associated with day shifts had a severe increase in blood pressure and heart rate (fig. 2).

We noticed that night shift workers frequently experienced rises in glycemia, dyslipidemias (2) and significant rises in heart rate, which betray a sympathetic hyperactivity.

All these increased biological values represent risk factor for developing coronary events.

One of the patients from group I suffered a myocardial infarction during the study period, and a further two developed diabetes.

TI	37	M	135/90	VA	38	M	140/90

DISCUSSION

Comparing systolic and diastolic blood pressures in patients of the 2 groups at the end of the study period, we observed a significant difference in systolic blood pressure as well as diastolic blood pressure, patients that performed great physical efforts associated with night shifts having significantly increased values compared to those performing mild effort during day shifts.

Increased physical effort determines a rise in cardiac output and cardiac frequency. Physical effort determines activation of the sympathetic nervous system. Moreover, night shifts increase blood pressure and affect the variability of heart rate (2).

All these mechanisms lead to an abnormal increase in blood pressure, increase that implies the necessity of medical treatment, the modification of the work program to day shifts with mild effort.

A rise in systolic blood pressure can lead to a decrease in the individual's effort limit and an increase of myocardial oxygen consumption.

CONCLUSIONS

The results of our study have important contributions in the practice of occupational medicine, referring to active hypertensive employees who work in terms of high professional physical effort and night shifts.

We have demonstrated that the association between work night shifts and high physical efforts leads to marked increases in blood pressure and heart rate, patients in question being frequently prone to coronary events.

Our research results have to be materialized in medical and administrative measures: workplace changing, decrease of working hours or occupational reorientation, the occupational physicians taking decision in supervision of hypertensive employee.

THE CLINICAL-EPIDEMOLOGICAL STUDY OF DRUGS USED TO TREAT ARTERIAL HYPERTENSION AND COMORBIDITIES ASSOCIATED

Maria-Magdalena Leon, F Mitu
University of Medicine and Pharmacy "Grigore T. Popa" - Iasi
Faculty of Medicine
Department of Internal Medicine
Discipline of Medical Semiology
Clinical Hospital of Rehabilitation Iasi

THE CLINICAL-EPIDEMOLOGICAL STUDY OF MEDICINE USED TO TREAT ARTERIAL HYPERTENSION AND COMORBIDITIES ASSOCIATED (Abstract): **Aim:** The objective of this study was to investigate the drug treatment of AHT according to the grade and associated comorbidities: diabetes, chronic kidney disease, angina pectoris. M**aterial and methods:** This study is a retrospective one, comprising a total of 1064 patients admitted to the Clinical Rehabilitation Hospital Iasi, Cardiovascular Rehabilitation Clinic between 01.01.2011 - 31.12.2012. We noted the epidemiological data on the distribution of AHT according to area of origin, sex, age, and the pharmacological treatment according to the AHT grade and related diseases. **Results:** The results obtained were statistically analyzed by comparing drugs used together, their number depending on the AHT grade and associated comorbidities in order to achieve target values of blood pressure and reduce cardiovascular risk. The strategies used to control blood pressure were the gradual increase of the dose of drug or its replacement, switching from monotherapy to combination therapy, starting treatment with two drugs or administration of fixed combinations. **Conclusions:** The most used antihypertensive drugs were the angiotensin receptor blockers, ACE inhibitors, calcium blockers, diuretics and beta blockers. Some patients have even received triple therapy. **Keywords**: ARTERIAL HYPERTENSION, DIABETES, ANGINA PECTORIS, CHRONIC KIDNEY DISEASE.

Arterial hypertension (AHT) is a major risk factor for cardiovascular and renal diseases, being considered the leading cause of death. Worldwide, the disease prevalence reaches 40%, and 44.92% in Romania, prompting the need for guidelines use in order to optimize treatment (1.2). The fundamental objectives of AHT treatment are getting target values of blood pressure (BP) and reducing cardiovascular risk (3, 4). A meta-analysis that aimed at 147 clinical trials highlighted the need of lowering BP, as a reduction of 10 mm Hg of systolic blood pressure and of 5 mm Hg of diastolic one causes a decrease of 20% in the risk of coronary heart diseases and of 32% in the risk of cerebrovascular accidents in a year (5, 6).

MATERIAL AND METHODS

The aim of this study was to investigate the drug treatment of AHT according to

AHT grades and associated co morbidities: diabetes, chronic kidney disease and angina pectoris. This is a retrospective study, based on data obtained from observation sheets of a total of 1064 patients hospitalized at the Clinical Rehabilitation Hospital Iasi, Cardiovascular Rehabilitation Clinic between 01.01.2011 - 31.12.2012. This study evaluated the association of antihypertensive drugs and their effect on blood pressure value. Most hypertensive patients required more than one antihypertensive agent, so we started with the lowest dose (for patients without risk or low risk) and in patients with uncontrolled BP, doses were increased gradually until the onset of maximum effect or associated with other antihypertensive drugs.

RESULTS AND DISCUSSION

The prevalence of AHT is 38.72% men and 61.28% women aged 40-80 years (fig. 1), as follows: 21.52% under the age of 55, 40.70% between 55-65 years and 37.78% over the age of 65, being moderately prevalent in women, rural 51.03% (48.97% urban) (fig. 2, 3).

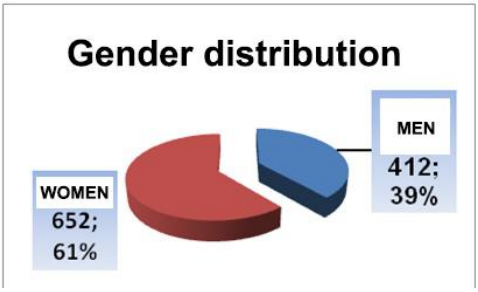

Fig. 1. Gender distribution

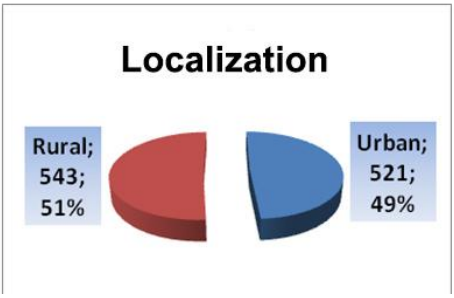

Fig. 2. Distribution on backgrounds

Consistent with literature data the age group most affected by AHT presence remains 55-65 years, predominantly females, as this age group lacks hormonal protection (fig. 4).

A a growth of AHT grade 3 of 47.84% was showed as compared with AHT grade 2 -28.29% and AHT grade 1 - 23.87% grade 1, but the difference is not statistically significant.

According to this study, associated morbidities are found in the following percentages: 26.50% diabetes mellitus (DM) 18.61% angina pectoris (AP), 14.66% peripheral artery occlusive disease (PAOD), 6.02% chronic kidney disease (CKD) (fig. 5).

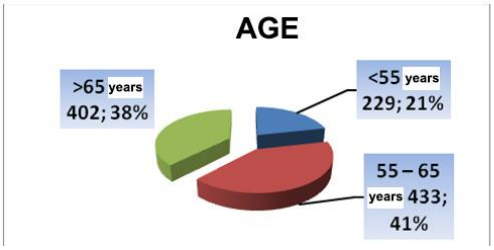

Fig. 3. AHT distribution on age

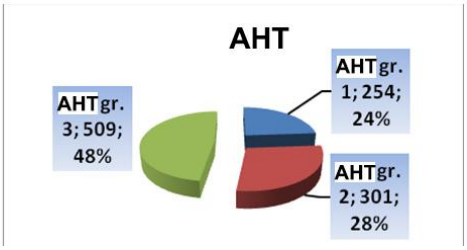

Fig. 4. Distribution on AHT grades

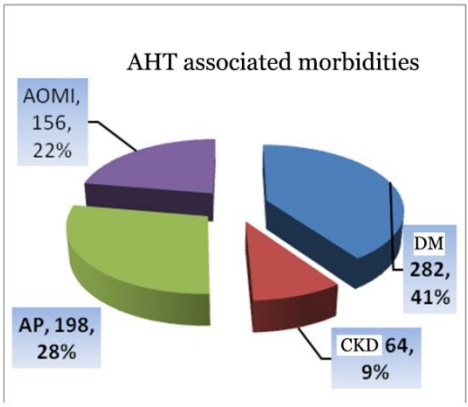

Fig. 5. Morbidities associated to AHT

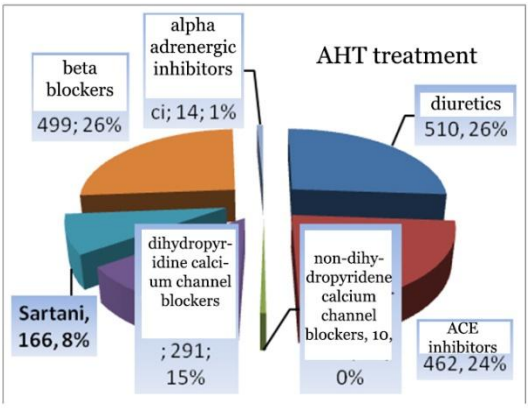

Fig. 6. AHT treatment

AHT treatment guidelines developed by the European Society of Cardiology (ESC) in 2007 and updated in 2009 support the importance of a "customized" therapy to the detriment of "staged" therapy, and recommend the use of different classes of antihypertensive and certain preparations of each class, with certain features (tab. I):

TABLE I

Treatment of HTA and co morbidities according to guidelines

HTA+comorbidities	**Recommendations therapeutic classes guidelines**
Angina pectoris	BB, CCB
Heart failure	Diuretics, BB, ACE inhibitors, ARBs, antialdosterone
Chronic kidney disease	ACE inhibitors, ARBs, loop diuretics
Diabetes mellitus	ACE inhibitors, ARBs

ACE inhibitors= Inhibitors of angiotensin converting enzyme; BB= Beta-blockers;
ARBs= angiotensin receptor blockers II /sartans; CCB= Calcium channel-blockers

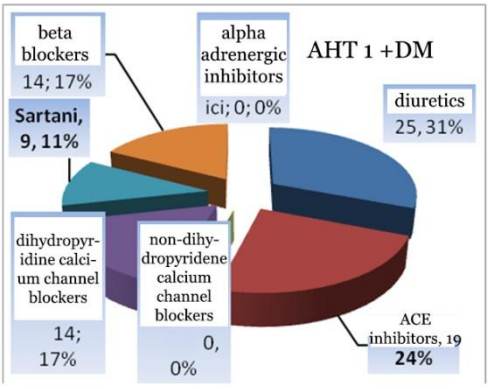

Fig. 7. Treatment of AHT grade 1 associated with DM

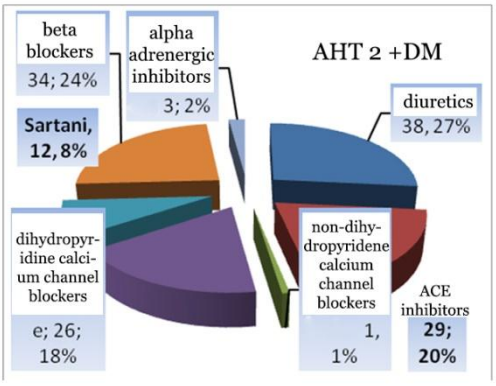

Fig. 8. Treatment of AHT grade 2 associated with DM

In our study we used different classes of antihypertensives, depending on the AHT grade and the presence of DM. along with AHT grade, the percentage of patients treated with alpha adrenergic inhibitors increases, but the increase is minimal (0 vs. 3.2% vs. 4.1%). The most significant change for all AHT grades can be found in case of beta blockers, which double at every increase in AHT grade (14.17% vs. 34.24% vs. 76.21%) ($p < 0.01$). Diuretics increase moderately from grade I to II (25.31% vs. 38.27%), and subsequently they have an exponential growth (38.27% vs. 93.26%) ($p < 0.01$), statistically significant. The same trend can be found in ARBs (9.1% vs. 12.8% vs. 42.12%), ACE inhibitors (29.2% vs.. 19.24% vs.. 83.23%), dihydropyridine calcium blockers (14.17% vs. 26.18% vs. 55.16%). In statistical terms, the greatest increase from grade I to grade III can be found in case of beta blockers (the other increases are also statistically significant) (fig. 6, 7, 8).

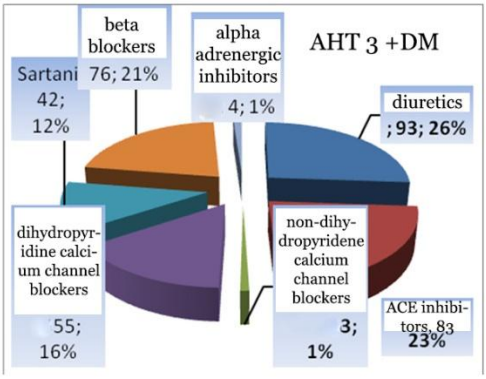

Fig. 9. Treatment of AHT grade 3 associated with DM

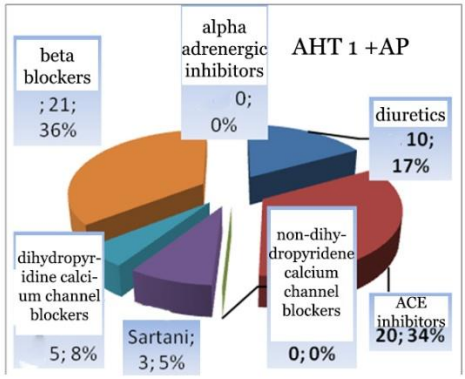

Fig. 10. Treatment of AHT grade 1 associated with AP

In our study, for the treatment of AHT associated with angina pectoris we used different medications, whose percentage ranges from one AHT grade to another. Thus, non-dihydropyridine calcium channel blockers were not used in the treatment of AHT grade 1 and 2, and a small percentage of 3.1% received these drugs in case of AHT grade 3 associated with AP. The same trend was found and the use of alpha adrenergic inhibitors (fig. 9, 10).

Diuretics were used in all grades of AHT (10.17% vs. 22.29% vs. 33.15%), and a statistically significant increase could be noted. ACE inhibitors were administered in case of AHT grade 1 in 20.34% of patients, then the percentage was dropped in case of AHT grade 2 (16.21%), and in AHT grade 3 it had a statistically significant increase (58.26%). Beta blockers were given in similar percentages in case of AHT grades 1 and 2 (21.36%, 24.32%) and in AHT grade 3 an exponential increase, statistically significant appeared (63.29%). Sartans have a similar tendency to beta blockers in all grades of hypertension (fig. 11, 12).

In case of a combination between CKD and HTA, we did not use as a treatment for AHT grades 1 and 2 alpha adrenergic inhibitors and non-dihydropyridine calcium channel blockers while in case of grade 3 percentage is minimal (2.3%, 1.1%) (fig. 13, 14).

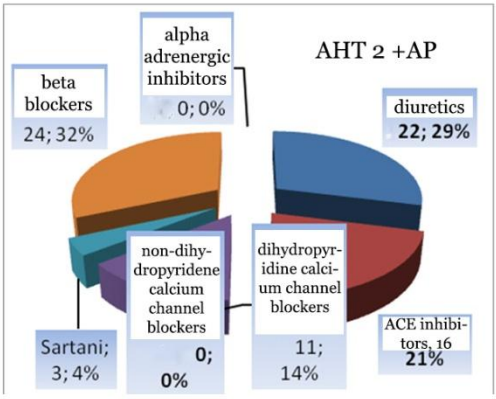

Fig. 11. Treatment of AHT grade 2 associated with AP

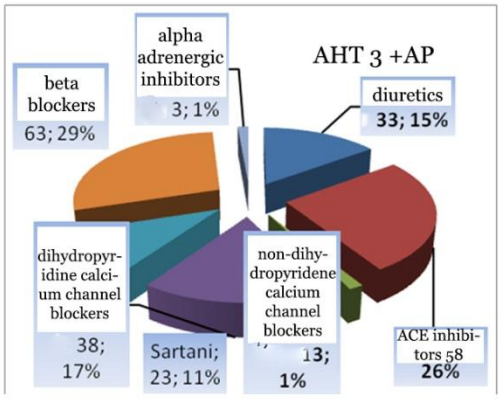

Fig. 12. Treatment of AHT grade 3 associated with AP

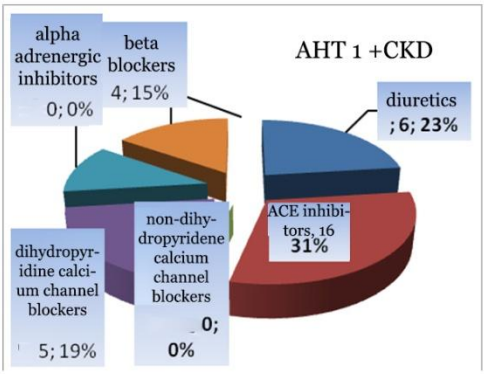

Fig. 13. Treatment of AHT grade 1 associated with CKD

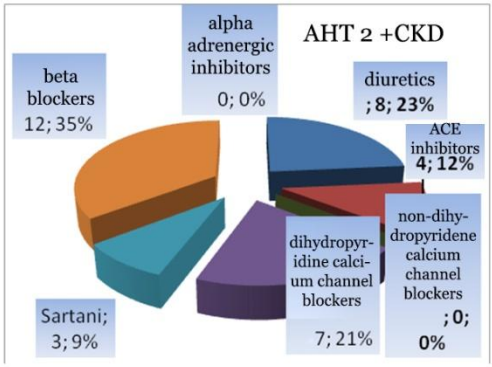

Fig. 14. Treatment of AHT grade 2 associated with CKD

Diuretics have a linear increase in HTA grades 1 and 2 (6.23% vs. 8.23%), subsequently exponential, statistically significant (21.26%). The same trend is observed in case of dihydropyridine calcium blockers and ACE inhibitors. Beta blockers significantly increase along with the AHT grade (4.15% vs.. 12.35% vs.. 19.24%) (fig. 15).

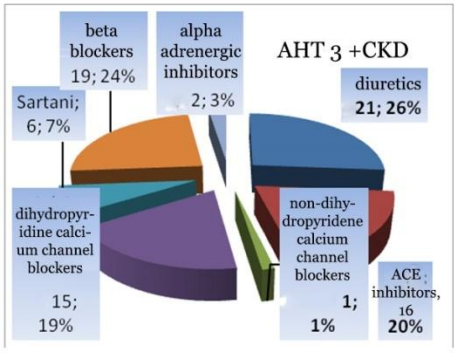

Fig. 15. Treatment of HTA grade 3 associated with CKD

CONCLUSIONS

According to current guidelines, clinical and laboratory evaluation of hypertensive patients aims to improve lifestyle through the identification of cardiovascular risk factors or clinical conditions that may influence the AHT prognosis and treatment, identification and exclusion of secondary causes of AHT and determination of the presence of target organ damage and quantification of its grade. Treatment of hypertension is also a challenge. Hypertension therapy involves both behavioral changes regarding living arrangements and customized pharmacological treatment. But hypertension can coexist with other co morbidities and thus treatment should be individualized as to not interfere with other diseases.

According to the study, AHT has a greater incidence in diabetic patients as compared to non-diabetic population of the same age. It is often associated with obesity, insulin resistance and hyperinsulinism. The AHT presence in a diabetic patient increases five times the incidence of myocardial infarction and stroke. Note that the occurrence of DM in a hypertensive patient puts the latter in a high risk group with the highest cardiovascular risk.

The goals of the pharmacological treatment of angina pectoris are to improve quality of life by reducing the severity and frequency of symptoms and thus patient's prognosis.

AHT is both a consequence and a cause of renal disease (6.02%), regardless of etiology. AHT is a major determinant of renal disease progression. Accelerated or malignant hypertension, renal artery stenosis and arterio-embolic disease are important causes of the kidney disease.

Strategies used to control blood pressure were moving from monotherapy to combinations, starting treatment with two drugs or administration of fixed combinations. Most used were angiotensin receptor blockers, ACE inhibitors, calcium blockers, diuretics and beta blockers. Some patients received even triple therapy to obtain normal values of blood pressure.

PHYSICAL ACTIVITY MONITORING ADVANCES AND LIFESTYLE INTERVENTIONS IN OBESITY

Obesity represents a strong risk factor for developing chronic diseases. Strategies for disease prevention often promote lifestyle changes encouraging participation in physical activity. However, determining what amount of physical activity is necessary for achieving specific health benefits has been hampered by the lack of accurate instruments for monitoring physical activity and the related physiological outcomes. Activity monitors have evolved from step counters and measuring devices of physical activity duration and intensity to more advanced systems providing quantitative and qualitative information on the individuals activity behavior. The novel techniques can monitor modes of sedentary behavior as well as the engagement in specific activity types that helps to evaluate the effectiveness of lifestyle interventions. In conclusion, advances in activity monitoring have the potential to support the design of response-dependent physical activity recommendations that are needed to generate effective and personalized lifestyle interventions for health promotion. (Advances in physical activity monitoring and lifestyle interventions in obesity. A G Bonomi, K R Westerterp. Journal: International Journal of Obesity - *Int J Obesity*, vol. 36, no. 2, pp. 167-177, 2012).

HAND, FOOT AND MOUTH DISEASE – OUTBREAK IN ROMANIA? (Abstract): Hand, foot and mouth disease (HFMD) is a viral illness usually occurring during the summer months in children younger than 5 years of age. In the North-East area of Romania the incidence is usually low, each dermatologist reporting 1-2 cases or even less per year. The diagnosis is usually based on the characteristic clinical aspect: vesicles and papules on the hands and feet and superficial oral ulcers. HFMD is typically a benign and self-limiting disease that resolves in approximately 7 days; in Asia there have been few reported severe cases that developed neurological complications and even death, while in certain areas of China this disease is a more and more serious public health problem. In the summer of 2012 in North-East Romania numerous cases of disease have been reported, some with atypical clinical manifestations and most of them with mild or moderate forms of disease. The present article is a discussion on one of these cases. The diagnosis was made based on lesions location and clinical appearance. An outbreak of HFMD should be confirmed by virology tests. **Keywords**: HAND, FOOT AND MOUTH DISEASE, EPIDEMIC

Hand, foot and mouth disease (HFMD) is a viral infection that produces vesicles and papules on the hands and feet and superficial oral ulcers (1).

Enteroviruses are RNA viruses belonging to the *Picornaviridae* family; more than 100 human serotypes are described in the literature, including 3 polioviruses, 23 coxsackie viruses A, 6 coxsackie viruses B, 31 echoviruses and 39 enteroviruses (EV68-71, EV 73-102, EV 104-107 and EV 109). From a phylogenetic point of view, there are four species of enteroviruses: A, B, C, and D (1).

The highest incidence of severe forms of disease and also the longest delay from the onset of symptoms to disease diagnosis is recorded in children. Boys are generally more susceptible to catching this disease, and a single day delay in diagnosis could increase the risk for severe forms of illness by approximately 40% and of death by

54% (2). All cases suspected of HFMD in North-East Romania in the summer of 2012 were mild and healed completely.

The disease is mainly transmitted by fecal-oral (HFMD being one of the dirty hands spread diseases) and respiratory routes. HFMD is highly contagious, especially with children 2 years old or younger, but also family members of even community. In literature cases of re-infection among brothers have been described. A person is most contagious during the first 7 days of illness, although enteroviruses persist for 1 to 4 weeks in the nose or pharynx and up to 18 weeks in stool (1).

CASE REPORT

We present a case of hand, foot and mouth disease in a 4-year-old boy.

According to his parents the boy presented a prodromal fever. At physical examination we discovered a skin eruption consisting of small papules and round-oval vesicles located periorally and on the tongue (fig. 1), palms (fig. 2), sole side of the feet (fig. 4), upper and lower limbs, and buttocks (fig. 5). Onycomadesis (fig. 3), a non-painful shedding of the nail beginning at its proximal end in one or several fingers that resolves without complications, was also present in our patient. Submandibular lymphadenopathy, common finding in this disease, was not seen in our patient.

The diagnosis was made only on clinical grounds, because we could find no laboratory able to identify the virus in our case.

DISCUSSION

HFMD is a viral disease that affects the skin and oral mucosa.

Coxsackie virus A16 (CA16) was the first viral agent isolated from patients with HFMD; subsequently CA4, CA6, CA9 and CA10 as well as Coxsackie virus B (CB) were demonstrated as pathogens in HFMD (4). HFMD caused by EV71 has a higher incidence of neurological complications including aseptic meningitis, acute flaccid paralysis and encephalitis. Outbreaks of HFMD have occurred in Malaysia (2000-2003), Taiwan (1998-2005), Singapore (2000), Brunei (2006), Thailand (2008-2009), Korea (2008-2009) and Hong Kong (2008); therefore, the development of EV71 vaccine has become a national priority in Japan and China (3).

Human enterovirus 71 belongs to the human enterovirus A species of *Enterovirus* genus within the family of *Picornaviridae*; it is considered the major causative agent of HFMD, especially in children younger than 5 years of age, with children ages 1.0 to 2.9 years old being the most susceptible (5). EV 71 is more frequently associated with severe forms of disease or death.

Fig. 4 Plantar vesicles and lesions of lower limbs

Fig. 5. Buttock lesions

The diagnosis is clinically suspected in more than 90% of the cases, especially in the outbreak context, in our patient being made based on lesion location and clinical appearance. In Romania, the incidence of HFMD is usually low, with only 1-2 or even no cases diagnosed per year by every dermatologist. Nevertheless, in the summer of 2012 in North East Romania there was a three- or even four-fold increase in the number of reported cases. The diagnosis of certainty relies on virology lab tests: PCR for the detection of enteroviruses in blood, nasopharynx, and stool. Despite that, to our knowledge, there are no laboratory-based molecular studies on HFMD outbreak in Romania; the initially suspected outbreak has to be confirmed.

HFDM starts with a prodrome of fever, malaise, anorexia, and oral mucosal pain. These prodromal symptoms are more common in children younger than 5 years of age and precede the onset of specific lesions by 24-72 hours. In our case, the patient presented prodromal fever (5).

Skin rush manifests with small papules and especially round-oval vesicles classically located on palms and sole side of the foot; however they can be also present on the upper and lower limbs, buttocks, periorally, and even sporadically on the trunk. The typical appearance described in reference books, with lesions located solely on palms and accompanied by oral lesions, is today more rarely noticed, our case also presenting lesions located in other regions than classically described. The rash was neither pruritic nor left scars, while the vesicles were surrounded by an inflammatory halo.

Oral lesions are classically described on the anterior oral mucosa and tongue and are reported as being extremely painful, the vesicles progressing rapidly to superficial ulcers that heal typically without scars in approximately 7 days. When presenting to the dermatologist our patient had ulcerative lesions of the oral cavity and perioral vesicular lesions covered by crusts. Although in some cases cervical and submandibular lymphadenopathy may be present, our patient was lymphadenopathy-free (5).

Onycomadesis, a non-painful total separation of nail plate from the nail bed that begins at the proximal area and progresses to the free edge with nail shedding as a result of the temporary cessation of nail formation, was also present in our patient. Onycomadesis accompanying outbreaks of Coxsackievirus and enterovirus 71 has been reported in 2008 in Spain and Finland to be associated with HFMD (6). The mechanism of onycomadesis occurrence in HFMD has caused numerous debates, and it still remains a pathogenic hypothesis with several possible causes: selective tropism of certain viruses for the nail matrix; systemic effect of sepsis (nevertheless fever is not constant in HFMD), or maybe post-inflammatory consequence of periungual vesicles (7).

CONCLUSIONS

HFMD has variable expressivity, and its early diagnosis (now by modern molecular techniques) helps initiate control measures aimed at stopping virus transmission. Routine public health surveillance programs could be useful in understanding and monitoring the epidemiology of HFMD in Romania.

NEW THIAZOLES DERIVATIVES AS POTENT ANTIMICROBIAL AGENTS

Thiazoles are a familiar group of heterocyclic compounds possessing a wide variety of biological activities, and their usefulness as medicines is well established. Bondock et al. synthesized a series of novel 2-(3- pyridyl)-4,5-disubstituted thiazoles and characterized them by spectral and elemental analyses. The newly synthesized compounds were evaluated for their *in vitro* antimicrobial activity against ten bacterial and five fungal human pathogenic strains using the disc diffusion assay. The results clearly revealed that the substituted 2-(3-pyridyl)thiazoles exhibited good antimicrobial activity. The best antimicrobial activity was observed for 5-acetyl- 4-methyl-2-(3-pyridyl)thiazole followed by 4-methyl-2-(3-pyridyl)thiazole. Increasing the size of the substitutions either at position 4 or 5 on the thiazole nucleus decreased the antimicrobial activity. Among the synthesized compounds, 5-acetyl-4-methyl-2-(3-pyridyl)thiazole exhibited two-fold antibacterial activity of ampicillin in inhibiting the growth of *Staphylococcus epidermidis* (MIC=0.24 mg/mL) and also showed equipotent antifungal activity with amphotericin B against *Geotricum candidum* (MIC=0.48 mg/mL). In conclusion, the authors synthesized and investigated the antimicrobial activities of some new 2-(3-pyridyl)-4,5-disubstituted thiazoles with the aim of discovering new structures that could be used as potent antimicrobial agents (Bondock S, Naser T, Ammar YA. Synthesis of some new 2-(3-pyridyl)-4,5-disubstituted thiazoles as potent antimicrobial agents. *Eur J Med Chem* 2013; 62: 270-279).

EXPRESSION OF BMI-1 PROTEIN IN CERVICAL, BREAST AND OVARIAN CANCER (Abstract): B-cell-specific Moloney murine leukemia virus integration site 1 (Bmi-1) is a member of polycomb group, which participates in axial patterning, hematopoiesis, cell cycle regulation, and senescence. Overexpression of Bmi-1 has been reported in various human cancers and proved to be associated with poor survival. **Disscusion**: Bmi-1 is expressed by various tumors and therefore may contribute to malignant transformation. Bmi-1 not only can lead mammary epithelial cells to senescence and immortalization, but also plays a key role in breast cancer. A significant correlation was observed between Bmi-1 expression and axillary lymph node metastases in lymph-ductal breast cancer. Bmi-1 is expressed in cervical cancer and correlated with a poorer prognosis, suggesting that this protein participates in the development and progress of cervical cancer. Regarding ovarian cancer, the results of several immunohistochemical studies revealed overexpression of Bmi-1, especially in poorly differentiated ovarian carcinoma. There is a strong correlation between histological grade, clinical stage and its expression. **Conclusions**: Human genes of polycomb group correlated with various hematological and epithelial cancers identify new mechanisms of malignant transformation and pave the way for developing new cancer treatments and identify new diagnostic markers. Bmi-1 and its expression in tissues taken from patients with cervical, breast and ovarian cancer could be a marker for diagnosis and prognosis, and not least a potential target of antitumor therapy. **Keywords**: BMI-1 PROTEIN, IMMUNOHISTOCHEMISTRY, ANTITUMORAL THERAPY

B-cell-specific Moloney murine leukemia virus integration site 1 (Bmi-1) is a member of the polycomb group, involved in hematopoiesis, cell cycle and cell aging. Recently, Bmi-1 overexpression has been reported in many cancers and was associated with a low survival rate (1). Human polycomb group genes related to various hematologic and epithelial cancers, identify new mechanisms of malignant transformation and open a path to developing new cancer treatments and identifying new diagnostic markers.

Polycomb group proteins are silent genes with key roles associated with body development by at least two multimeric complex: polycomb repressive complex 1 (PRC1) and repressive complex 2 (PRC2). Bmi-1 protein, a core member of PRC1 complex, was identified as oncogene and

together with c-myc initiates the occurrence of lymphoma. Bmi-1 gene is located on human chromosome 10p11.23 and extends over 4.9 kb, comprising 10 exons and 9 introns. It contains a RING finger domain type in its N-terminal end, and a central helix-turn-helix motif, which is required for inducing telomerase activity and immortalization of human epithelial cells (2).

It has been shown that Bmi-1 would be involved in several biological processes, such as embryonic development, organ formation, tumorigenesis, stabilization and differentiation of stem cells (3). Bmi-1 is expressed ubiquitously in almost all tissues and its expression was found to be slightly higher in the brain, spinal cord, kidneys, lungs, gonads, and placenta. However, several studies have shown that Bmi-1 expression is frequently increased in various human cancers, including lung cancer, ovarian cancer, acute myeloid leukemia, nasalpharyngeal carcinoma, breast cancer, and neuroblastoma, indicating that Bmi-1 could play important roles in the initiation and progression of cancer. The oncogenic feature of Bmi-1 was also reported to be associated with cell protection from apoptosis (4).

DISCUSSION

***Ovarian cancer*.** Prognosis of ovarian cancer has not improved substantially by standard classical treatment, in spite of new surgical techniques, chemoresponsivness of this malignancy to classical cytostatic agents, and efforts to detect it in early stages, accounting for the current global interest in ovarian cancer research. Recent molecular biology and genetic researches focus on the detection of molecular-genetic defects associated with this type of cancer, and their relation with morphopathological and clinical-imaging aspects and distinct clinical developments, which ultimately have direct therapeutic implications: molecular treatment targeting the molecular defect, customized treatment, with impact on survival (5).

Ovarian cancer has the highest mortality rate of all gynecologic malignances (6). Despite an initial response to surgery and first-line platinum- or taxane-based chemotherapy, most tumors eventually develop drug-resistant relapse. Evidence suggests that resistance to cipslatin may be the result of a defective apoptotic program. In this case, increased levels of DNA damage would be required to induce apoptosis initiation signal (7).

To investigate whether the abnormal presence of Bmi-1 is involved in the pathogenesis of ovarian carcinoma in a study conducted at the Oncology Laboratory of Sun Yat-Sen University, China in 2010, protein expression was first examined immunohistochemically in normal, benign, and borderline ovarian tissue and tissues from epithelial ovarian cancers. The results demonstrated that Bmi-1 expression in all normal ovary specimens was absent or low. In ovarian tumor specimens, a significantly increased Bmi-1 expression was observed in benign cystadenoma to borderline tumor, and carcinoma. Moreover, it was found that the frequency of Bmi-1 expression in undifferentiated ovarian carcinomas was significantly higher than in other types of carcinoma. Higher Bmi-1 expression in ovarian cancers was strongly correlated with tumor histological grade and clinical stage (pT / pN / pM). These findings suggest that Bmi-1 overexpression in ovarian carcinoma may be an acquired feature of the malignant phenotype (8).

Breast cancer is the most common malignancy in women, its mortality and morbidity continuing to grow despite the re-

markable progress in diagnosis and therapeutic approach in recent years. In the past decades, there was a continuous concern for the early detection of breast cancer and development of effective treatment modalities which to lead to a decline in breast cancer deaths and improved quality of life for women struggling with this disease. Along with conventional histopathological diagnosis of malignant breast tumors, which grades and classifies them into microscopic subtypes, significant progress in assessing the prognosis of these patients was made with the investigation of some immunohistochemical markers involved in tumor carcinogenesis.

Invasion and metastasis processes that cause great mortality are extraordinary distinctive features of breast cancer progression. Although lymph node metastases, tumor size, and histological grade of differentiation are usually considered to be prognostic markers for metastases, these occur at distant sites in 20-30% of the patients without lymph node involvement (9). So far, Human Epidermal Growth Factor Receptor (HER-2/neu), c-myc, and HOXB9 emerged as metastasis risk predictors in breast cancer. Their aberrant expression can induce the expression of growth and angiogenic factors, resulting in higher local concentrations of these factors in the tumor microenvironment, thus favoring tumor progression (10).

Bmi-1 overexpression increases motility and invasive properties of mammary immortalized epithelial cells, which is concomitant with increased expression of mesenchymal markers and decreased expression of epithelial markers. Consistent with these observations, Bmi-1 repression in metastatic breast cancer cells remarkably reduces cell motility, invasion, and transformation, as well as metastasis and tumorigenesis in mice. It has been demonstrated that Bmi-1 promotes invasion and metastasis of breast cancer and predicts poor survival (11).

Bmi-1 mRNA is significantly higher in adjacent normal breast tissue in breast cancer patients compared with normal breast tissue from patients with non-cancerous lesions. By contrast, Mel-18 mRNA level is lower in normal tissues of patients operated for breast cancer compared with breast tissue from mammoplasty. When protein expression in these two genes was evaluated, it was noticed that most epithelial cells were positive for Bmi-1 in both groups of tissue samples, although expression intensity was stronger in the normal tissue of cancer patients. Bmi-1/Mel-18 ratio can be used as a tool to stratify women at risk for developing malignancies (12).

Early detection of breast cancer is critical for improving patients' chances of survival. Techniques designed to detect recurrent or metastatic disease in the preclinical stages can contribute to this goal. The presence of Bmi-1 oncogene in plasma was assessed in a wide range of primary breast carcinomas with the aim at investigating its correlation with tumor clinicopathological parameters and survival rate. Study results suggest that Bmi-1 expression may be a marker of poor prognosis and clinically it may become a noninvasive diagnostic marker (13).

Cervical cancer. Despite significant progress in the etiology, diagnosis and treatment of cervical cancer, its incidence and epidemiology factors were not correspondingly influenced its resurgence in parallel with increased mortality both in as our country and worldwide being recognized. The reality is hard to justify and, especially, to accept, since it is the only

cancer with known etiology, viral, sexually transmitted, and cured 100%, of course in early forms, by complex, multimodal treatment. Without minimizing the undeniable progress in its etiopathogenesis, diagnostic and therapeutic means, and methods of prevention and early detection, we believe that in this field modern medicine owes, and stronger action must be taken for decreasing the incidence and improving the treatment of the disease at curable stage. It is noteworthy that this is a cancer benefiting from early detection and prevention and coded therapy, likely to cure the patients. Cervical cancer is the second most common cancer in women worldwide, with approximately 500,000 new cases diagnosed and 250,000 deaths each year. Almost 80% of cases are from developing countries (14).

Virtually all cervical cancers (99%) are related to HPV (Human Papilloma Virus) infection. In our country, every year approx. 2,800 new cases are detected, situation similar to that in developing countries from Africa, Asia and South America. According to a study by the World Health Organization, the mortality rate in Romania is 2 to 2.7 times higher than in most Central and Eastern European countries, and 6.3 times higher than EU average, the main cause responsible for this high mortality being the same factor: late diagnosis, and absence of mass screening programs, respectively. And this, in the conditions of a well organized and equipped network for the current practice of cervicovaginal exfoliative smear cytology. The natural corollary of the high incidence of cervical cancer mortality in our country is its proportional mortality, which, constantly in the last two decades, is the highest in Europe: 11.01 to 100,000 women (14).

The role of neoadjuvant chemotherapy in locally advanced cervical cancer has been studied in the past 25 years; this therapy reduces tumor size and lymph node positivity and allows minimizing the postoperative radiation therapy (15). Neoadjuvant chemotherapy, which can reduce the size and thereby increase tumor resectability, has been proposed as treatment of locally advanced cervical cancer. A study on a series of 110 patients, of which 68 received neoadjuvant chemotherapy and 42 were subjected to surgical procedure as the first therapeutic choice was conducted at the Peking University "People" Hospital. The results showed that 70.6% of patients achieved complete or partial response to neoadjuvant chemotherapy. Estimating the blood loss, duration of intervention, number of lymph nodes removed, the rate of complications during and after surgery, no significantly differences between the 2 groups were recorded. However, the rate of lymph-vascular space involvement was lower in the group who received neoadjuvant chemotherapy (16).

Neoadjuvant chemotherapy together with radical surgery increase the disease-free interval (DFS) and overall survival (OS) of patients with locally advanced cervical cancer compared with surgery as the first therapeutic act (17).

Bmi-1 is expressed in cervical cancer and correlates with a poorer prognosis, suggesting that this protein could participate in the development and progression of cervical cancer. It can be an independent prognostic of overall survival rate (18).

In a study by the Department of Gynecology and Obstetrics, University of Wurzburg, Bmi-1 expression in ovarian, breast, cervical and endometrial cancer tissues was determined by Western blot and

immunohistochemistry techniques. The results showed that Bmi-1 protein was significantly increased (19).

CONCLUSIONS

Bmi-1, polycomb group gene, regulates the proliferative activity of normal stem and progenitor cells. It is also essential for self-renewal of neural cells and hematopoietic stem cells. Bmi-1 is frequently increased in ovarian cancer and correlates with clinical stage, presence of lymph node metastasis, and poor prognosis.

Bmi-1 protein expression is more pronounced in primary breast cancer tissues compared to adjacent non-cancerous tissues. Increased Bmi-1 expression is correlated with advanced clinicopathological classifications (T, N, M) and clinical stage. In addition, high Bmi-1 levels indicate a lower overall survival and serves as a marker of increased risk for breast cancer.

Polycomb group genes related to various hematological and epithelial cancers identify new mechanisms of malignant transformation and open the door to developing new cancer treatments and identify new diagnostic markers.

Bmi-1 expression in tissues collected from patients with cervical, breast and ovarian cancer could be a diagnostic and prognostic marker, and last but not least a potential target of antitumor therapy.

UNIVERSAL DNA VACCINE VECTOR

Kong *et al*. describe the development of recombinant attenuated *Salmonella Typhimurium* strains that can be used as universal platform for delivering DNA vaccines to stimulate mucosal, systemic and cellular protective immunities. These *S. Typhimurium* strains have features that enable them to colonize host tissues and allow the release of bacterial contents after lysis. The purpose of the study was to transform a recombinant attenuated *Salmonella* vaccine (RASV) strain into a universal DNA vaccine-vector. The strains were genetically modified to display a hyperinvasive phenotype, in order to maximize host entry and cell internalization, to enable endosomal escape and release of the DNA vaccine into the cytosol and to decrease *Salmonella*-induced apoptosis. This will allow efficient nuclear trafficking of the DNA vaccine for synthesis of encoded protective antigens. According to this study, a DNA vaccine encoding influenza virus HA antigen, delivered by RASV strain, induced complete protection to mice against influenza virus (Kong W, Brovold M, Koeneman BA et al. Turning self-destructing Salmonella into a universal DNA vaccine delivery platform. *Proceedings of the National Academy of Sciences*, 2012; DOI: 10.1073/pnas.1217554109).

CORRELATIVE STUDY OF PMA SCORING IN A GROUP OF ROMANIAN PATIENTS SUBMITTED TO TOTAL HIP REPLACEMENT (Abstract): Elective hip and knee prosthetic surgery represent the ultimate treatment option for pain and disabilities caused by arthrosis with these particular localizations. **Material and methods**: We conducted a preliminary retrospective study on a series of 47 patients investigated and operated at the Orthopedic Clinic of the Iasi Rehabilitation Hospital in the interval March 1, 2009- March 1, 2010. **Results**: A good correlation between the general preoperative and 3 month-postoperative PMA scores (r=0.746) was found, even though the correlations between individual parameters were only moderate. **Conclusions**: The obtained results show that mean preoperative PMA scores statistically differ from the scores recorded 3 months after surgery. **Key words**: TOTAL HIP REPLACEMENT, PMA SCORE, CORRELATION, QUALITY OF LIFE.

Elective hip and knee prosthetic surgery represent the ultimate treatment option for pain and disabilities caused by the arthrosis with these particular localizations (1). The prevalence of both diseases continues to increase mainly in economically developed countries due to surgical techniques improvement and general population ageing. This trend led to increased expenses for health services, and also to longer waiting lists and implicitly waiting time for the required elective surgery.

Clear and objective criteria must be defined for the selection of patients accepted or directed to these waiting lists; also, standard diagnostic tools should be defined to determine the priorities on these lists, and to accurately assess the true emergencies and optimal benefit for the patient. Chronologic criterion should not be considered alone, but in relation with the clinical and social impact of delayed surgery effects.

In 1994, in USA, about 124,000 total hip replacements were performed as compared to 119,000 interventions in 1990. While the frequency of surgical interventions increased by 4% from 1990, the mean hospital stay decreased by 33.3%, from 10.8 to 7.2 days on average. Also, during the same interval, the number of total knee replacements increased by 62% from 129,000 to 209,000, while mean hospital stay decreased by 35%, from 10.5 to 6.8 days (2-4). Even though this information is useful to evaluate

the money spent for health services, these are enough. More specific info is required mainly regarding changes in preoperative and postoperative patient health status in order to determine how much health we can buy for the spent money.

Large joint replacement (hip, knee) is efficient in most patients, being one of the most cost-effective interventions in all surgical domains. However, some problems may occur mainly in young patients and long-term results (5, 6).

The need for hip functional assessment by a numerical score came from the declared purpose to obtain accurate data regarding operative indications and postoperative results (7). Some scores are excessively detailed and complex, thus being difficult to use. As an example, the Harris Hip Score, a hip-specific instrument, evaluates pain, function, activity, and motion on a 0–100 scale (where 100 is the best). It allows easy data collection and electronic assessment, but its main drawback consists in the fact that only 5 points are awarded for mobility; thus, a bilateral, not painful ankylosis in extension is scored 50 to 100 points, while following arthroplasty a 60 degrees flexion with 2 Canadian crutches, slight pain in sitting position will determine a score of only 32 of 100 points.

Postel Merle d'Aubigne (PMA) score, first published in 1946 by Robert Merle d'Aubigné and Michel Postel (8), is a simple scoring system, three aspects of hip function being scored 0 to 6; thus, this score was adopted world-wide. In 1990, PMA score was modified, form used by us in the present study. The main changes consist in the introduction of two new elements without changing the original principle. Practically, the incidence is determined by the level of pain, and stability is dependent on walking quality, that is separate scores for each hip. This new PMA scoring system includes 3 items scored 0 to 6: pain, mobility and stability (with unilateral load bearing, including walking) for each hip.

MATERIAL AND METHODS

We conducted a preliminary retrospective study on a series of 47 patients investigated and operated between March 1, 2009 and March 1, 2010 at the Orthopedic Clinic of the Iasi Rehabilitation Hospital.

Statistical analysis was made with the help of SPSS17 software. Statistical analysis was based on the total numerical score of each parameter and not on the clinical staging. We performed a descriptive statistical analysis together with a correlative study were carried out in order to evaluate the relation between preoperative and 3 month-postoperative PMA scores.

In this patient series we have applied the PMA scores pre- and postoperatively in order to evaluate the results and the follow-up in total hip replacement surgery. The mean patient age was of 65.49 years. Most patients were from rural areas (70.21%). All patients were retired, this not being an absolute rule but a limitation of our study group.

The mean body mass index in our study group was of 27.1, indicating that most of our patients were overweight. The body mass index may be an essential indicator in preoperative, immediate or late postoperative assessment.

Continuous variables (interval) were characterized by calculating the main statistical indicators (mean and confidence interval 95%, median, standard deviation, dispersion).

RESULTS

In our study group there was an even gender distribution of the cases (23 males –

48.94% and 24 females – 51.06%), standard deviation (SD) of 0.505. Gender distribution is important to define the allowed post-surgery activities.

Age-group distribution is also important in the evaluation using PMA scores. In our patients mean age was of 65.49 years, with a standard deviation of 7.448 for a confidence interval of 95%. The youngest patient was 49 years-old, while the oldest was 81 years-old; the true mean age varied between 63.30 and 67.68 years and median age was of 65 years. Most patients belonged to the 60-70 years age group. The follow-up of quality of life parameters depends directly on gender, activity, occupation, and social integration level of each particular patient.

Rural-urban distribution of patients is an important factor to be considered as, at least in Romania, it may directly influence the level of individual activity and also the type of the activity to be developed.

In our study group a Pearson correlation index of 0.746 was obtained, suggesting a direct powerful correlation, as this result is very close to value 1. Sig. corresponding value is equal to 0.000 - that is we have obtained a significant correlation coefficient of 0.01, meaning that there are less than 1% chances to be wrong if we claim that between the two variables there is a significant correlation. Thus we may assert that there is a powerful correlation between preoperative and 3 month-postoperative PMA scores. Therefore, the lower the preoperative PMA score, the lower the chances for postoperative PMA score to get closer to 18 (meaning excellent results). However, some debatable aspects should be considered, such as the techniques and implants available in 2009 and other subjective factors that may influence the outcome.

We have also calculated the Spearman correlation coefficient on total and partial PMA scores of the 47 study patients. Spearman correlation scores were interpreted according to the following scale (9): low correlation (rho < 0.3); moderate correlation (0.3 < rho < 0.6); good correlation (0.6 < rho < 0.8); excellent correlation (rho > 0.8)

Analysis of the obtained PMA scores showed a good correlation (r = 0,746) between preoperative and 3-month-postoperative scores. This shows that the used method can evaluate with good accuracy specific aspects of life quality in total hip replacement patient. Nevertheless, some technical aspects remain difficult to separate during scoring evaluation, according to this scoring system. Next step was to perform individual correlations between the pre and postoperative PMA scores for pain, mobility, and stability.

For the pain score, correlation analysis showed the following results: preoperative PMA scoring showed a mean of 3.45 (scale 0-6), with a standard deviation (SD) = 0.686; postoperative PMA scoring showed a mean of 5.81, with a standard deviation (SD) = 0.398; preoperative pain showed a mean score of 3.45 (min=2, max=5) with a SD=0.686; postoperative pain showed a mean score of 5.81 (min=5, max=6) with a SD=0.398

A high symmetry of Spearman score (rho = 0.541) and Pearson (0.560) index was found. A moderate correlation between the scores for preoperative and 3-month-postoperative pain was noted. Thus, pain, as a subjective but relevant factor that may influence patient's quality of life requires detailed and further attention. Individual results illustrate a main subjective component in evaluating this score, while at 3 months postoperatively most patients show good pain scores. The lack of correlation between pre and postoperative scores

shows a random evaluation of preoperative pain and a uniform positive evaluation of the postoperative pain (mild to no pain).

For the range of motion (ROM) score, correlation analysis showed that: preoperative PMA scoring showed a mean of 4.11 (range 3-6), with a standard deviation SD = 0.890; postoperative PMA scoring showed a mean of 5.60, with a standard deviation SD = 0.496; preoperative ROM scoring showed a mean of 4.11 (min=3, max=6) with a SD=0.890; postoperative ROM scoring showed a mean of 5.81 (min=5, max=6) with a SD=0.496

We may observe a high uniformity for Spearman (rho = 0.493) and Pearson coefficients (0.496). As for the pain, there was a moderate correlation between the obtained scores for pre and 3-month-postoperative ROM.

ROM should also be considered for further detailed evaluation with special references to surgical technique and/or implant type.

As to the functional score (walking/stability), the correlation analysis provided the following results: preoperative PMA scoring showed a mean of 4.00 (range 3-6), with a standard deviation SD = 0.834; postoperative PMA scoring showed a mean of 5.43, with a standard deviation SD = 0.5; preoperative functionality recorded a score of 4 (min=3, max=6) with a SD=0.834; Postoperative functionality recorded a score of 5.81 (min=5, max=6) with a SD=0.5.

We may observe a high uniformity for Spearman (rho = 0.446) and Pearson (0.496) indices. As for the pain, there is a moderate correlation between the scores for pre and 3 month-postoperative functionality.

DISCUSSION AND CONCLUSIONS

A good correlation between the general PMA scores applied pre and 3 month-postoperatively (r=0.746), even if the correlations between individual parameters were only moderate.

The results obtained in the evaluation of our patient group show that the mean preoperative PMA scores statistically differ from the scores recorded 3 months after surgery. Thus, applying PMA questionnaires may be useful for a functional evaluation, but cannot highlight the importance of a specific implant or surgical technique. We have noticed that this questionnaire cannot make the difference between different prosthesis types and various surgical techniques that may represent important impact factors on patient's quality of life, mainly long-time after surgery. The used prosthesis influences the dynamic articular behavior and the indices for different scoring systems (PMA, Harris, AAOS).

Study groups should be organized so to include prospective and retrospective studies and further detailed statistical analysis will show the flaws of classic scoring systems.

NEWS

O ENZIMĂ ÎNDELUNG IGNORATĂ SE DOVEDEŞTE A FI CHEIA PENTRU A UCIDE BACTERIILE PATOGENE

Noi cercetări arată că o enzimă care a fost mult timp considerată relativ inutilă răspunsului imun are un rol important în determinarea celulelor sistemului imunitar să ucidă bacteriile care cauzează infecții. Cercetătorii de la Ohio State University au stabilit că această enzimă, numită caspase-11 la şoareci, permite componentelor celulare ale sistemului imunitar să fuzioneze şi să degradeze bacteriile care cauzează un tip de pneumonie numită boala legionarilor. Fără formarea fagolizosomului, aceste bacterii pot provoca boala. Nu se ştie dacă efectul este acelaşi şi contra altor bacterii. La om, enzima similară este o combinație de caspases 4 şi 5. Cercetătorii au stabilit că bacteria *Legionella pneumophila* suprimă activarea acestor două enzime din celulele umane. Dar, în cazul în care enzimele au fost reintroduse în celulele sistemului imunitar, au apărut aceleaşi evenimente de fuziune - observate şi la şoareci - care vor ucide bacteriile. Rezultatele ar putea duce la dezvoltarea de medicamente non-antibiotice concepute pentru a lupta împotriva anumitor infecții bacteriene prin activarea acestor enzime. Cei mai vulnerabili la boala legionarilor sunt fumătorii, vârstnicii, persoanele cu boli cronice sau compromise imunitar, inclusiv pacienții cu cancer şi SIDA. Majoritatea studiilor publicate până în prezent susțineau că fagocitoza era inițiată de o enzimă diferită, caspase – 1, iar caspase- 11 era necesară doar pentru activarea caspase- 1. Această concluzie se explică prin faptul că testele s-au făcut pe şoareci modificați genetic care nu aveau caspase- 1 dar nici caspase- 11 deoarece genele care codifică cele două enzime sunt situate foarte aproape una de alta. Datorită acestor studii, caspase-1 a fost considerată o țintă atractivă pentru tratament. Dar activarea caspase- 1 poate determina ca reacție adversă, o inflamație extinsă care nu apare la activarea caspase- 11, făcând din cea din urmă o ținta terapeutică mai dorită de companiile farmaceutice. Pentru noile studii, cercetătorii au utilizat culturi de celule umane şi şoareci modificați genetic, astfel încât aceştia să nu producă caspase-11. Ei au demonstrat că formarea fagolizosomului este activată de către caspase- 11 prin fosforilarea unei proteine țintă numită actin iar în celulele umane, bacteria *Legionella* a suprimat activarea caspases 4 şi 5, dar când au adăugat cele două enzime înapoi la culturile de celule imune ce conțin bacterii Legionella, bacteriile nu au mai supraviețuit. Activarea fagocitozei de către aceste enzime nu s-a produs în cazul altei bacterii patogene (*Salmonella*) ceea ce sugerează ca poate exista o diferențiere a acestor enzime funcție de tipul de bacterie (Anwari Akhter, Kyle Caution, Arwa Abu Khweek et al. Caspase-11 Promotes the Fusion of Phagosomes Harboring Pathogenic Bacteria with Lysosomes by Modulating Actin Polymerization. *Immunity*, 2012; DOI: 10.1016/j.immuni.2012.05.001Ohio State University (2012, June 11; Long-ignored enzyme turns out to be key to killing infectious bacteria. *ScienceDaily. MYASTHENIA GRAVIS ASSOCIATED WITH THYMOMA AND TOXIC MULTINODULAR GOITER. A CASE REPORT (Abstract): Adequate antithyroid drug treatment or surgery usually generates remission of myasthenia gravis (MG) in patients with thymus hyperplasia associated with Graves' hyperthyroidism. The case of a 46-year-old woman diagnosed with MG based on the clinical picture, anticholinesterase drug test and positive electromyography (EMG) is presented. The cervico-thoracic computer tomography revealed a compressive nodular goiter and normal antero-superior mediastinum and led to the diagnosis of MG secondary to the hyperthyroidism. An uneventful total thyroidectomy was performed, but postoperatively the MG symptoms worsened. Tc^{99m} tetrofosmin scintigraphy revealed an area of hyperfixation in the antero-inferior mediastinum, suggestive for thymoma, as confirmed by a repeated thoracic CT scan. Following a longitudinal sternotomy, a well incapsulated tumor of approximately 6/5 cm located in the antero-inferior mediastinum was found and an extensive thymomectomy was performed. The postoperative course was uneventful and the patient was discharged 9 days later with complete remission of myasthenia. The pathology report of the specimen revealed a mixt thymoma or AB thymoma after Muller-Hermelink and WHO classification, with invasive capsular foci corresponding to Masaoka II stadium. In conclusion, scintigraphy proved to be useful in the diagnosis and decision making of a thymoma. **Key words**: SCINTIGRAPHY, HYPERTHYROIDISM, MYASTHENIA GRAVIS, THYMOMA

The association between thyroid and thymus diseases, especially between Graves' hyperthyroidism and thymus hyperplasia with myasthenia gravis is reported in the literature but no standardized therapeutic standard is established. Both conditions can aggravate each other and a case tailored management is made by a multidisciplinary team.

The aim of this case report was to emphasize the role of a non-invasive imagistic investigation which resulted in operative decision making regarding a thymus lesion with a fatal potential if left untreated.

CASE REPORT

A 46-year-old woman, with a 2 years history of ocular, bulbar and limb muscles

weakness was admitted to the neurology department with inquiry myasthenia gravis.

Clinical examination, positive anticholinesterase drug test and positive EMG established the diagnosis of myasthenia gravis. The cervico-thoracic CT scan revealed a compressive nodular goiter (fig.1) and normal antero-superior mediastinum (fig. 2).

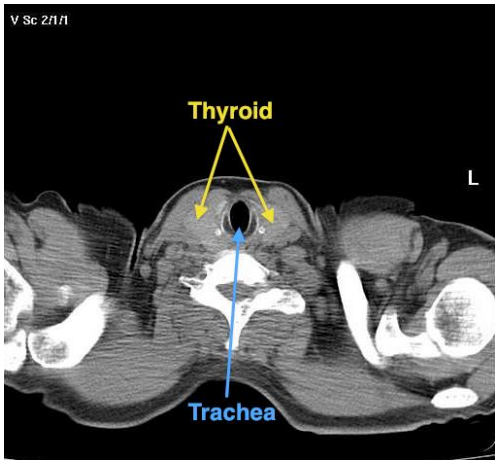

Fig. 1. The cervico-thoracic CT scan revealed a compressive nodular goiter

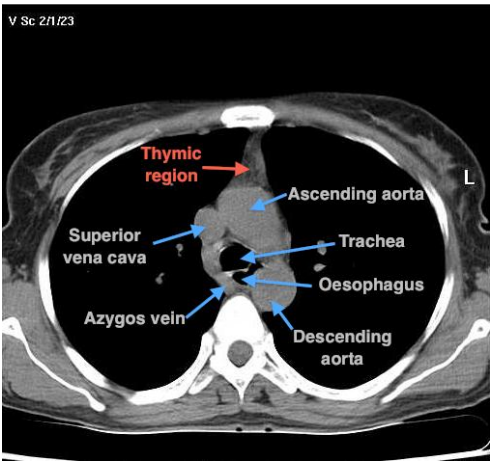

Fig. 2. The cervico-thoracic CT scan revealed a normal antero-superior mediastinum

Anticholinesterase treatment resulted in the improvement of the clinical condition and the patient was referred to the endocrinology department for further thyroid investigations.

Hyperthyroid status was revealed by hormonal tests (TSH-0.1 µUI/ml, fT4-1.2ng/dl) and ultrasound scan of the thyroid showed a multinodular goiter with degenerative areas and a total volume of 65.9 ml. Aspiration biopsy (FNAC) from the dominant nodule was benign. These findings led to the conclusion that myasthenia gravis was secondary to the hyperthyroidism and, given the large volume and nodular appearance of the goiter, the patient was referred to the surgical department for thyroidectomy. An uneventful total thyroidectomy was performed and the patient was discharged with thyroid hormone replacement and anticholinesterase treatment.

Pathology report of the goiter showed an oncocytic microfolicular adenoma with nuclear atypias and intact capsula in the left lobe and a mediofolicular adenoma with sclerohialinosis in the right lobe, developed on the multinodular goiter

Despite the expectations, five months after thyroidectomy the myasthenia gravis symptoms worsened, requiring higher anticholinesterase doses. At this stage we decided for an alternative imagistic exploration of the thymus, namely the ^{99m}Tc tetrofosmin scintigraphy. This revealed an area of hyperfixation of the radiotracer in the antero-inferior mediastinum, distal to the normal thymus location (fig. 3).

A new CT scan of the thorax showed a well delineated tumor located in the left parasternal antero-inferior region, lower than normal anatomical site of the thymus (fig. 4). Given the concordance of the two explorations, the diagnosis of thymoma with myasthenia gravis clinical stage Osserman IIB was established.

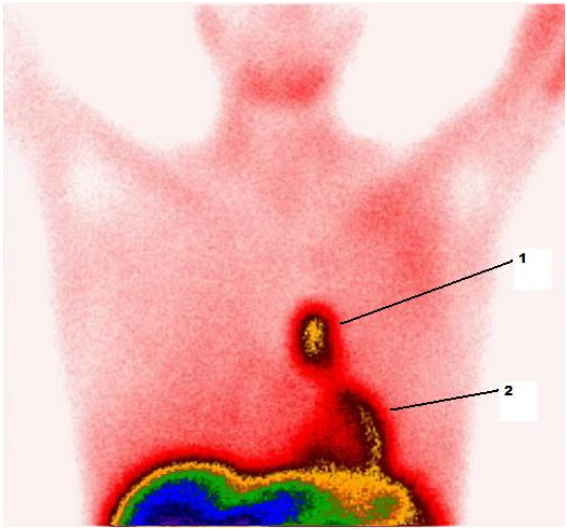

Fig.3. ^{99m}Tc tetrofosmin scintigraphy revealed an area of hyperfixation of the radiotracer in the antero-inferior mediastinum, distal to the normal thymus location

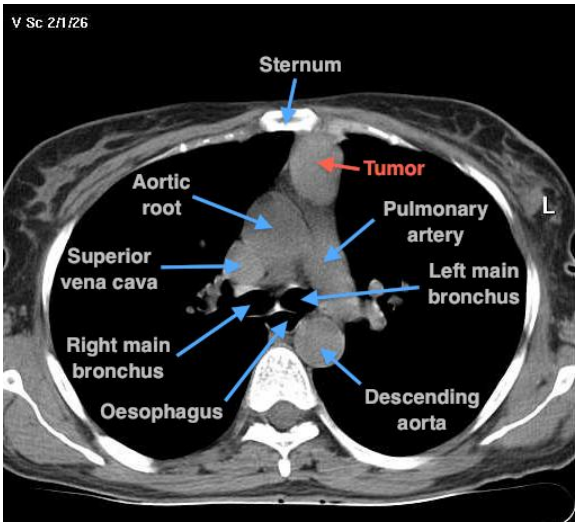

Fig. 4. A new CT scan of the thorax showed a well delineated tumor located in the left parasternal antero-inferior region

The patient was readmitted in the surgical unit and was operated on through a longitudinal sternotomy. Intraoperative exploration revealed a well encapsulated tumor of approximately 6/5 cm located in the antero-inferior mediastinum and an extensive thymomectomy was performed.

The pathology report of the specimen revealed a mixt thymoma or AB thymoma after Muller-Hermelink and WHO classification, with invasive capsular foci corresponding to Masaoka II stadium (fig. 5).

The postoperative course was uneventful and the patient was discharged 9 days later with complete remission of myasthenia.

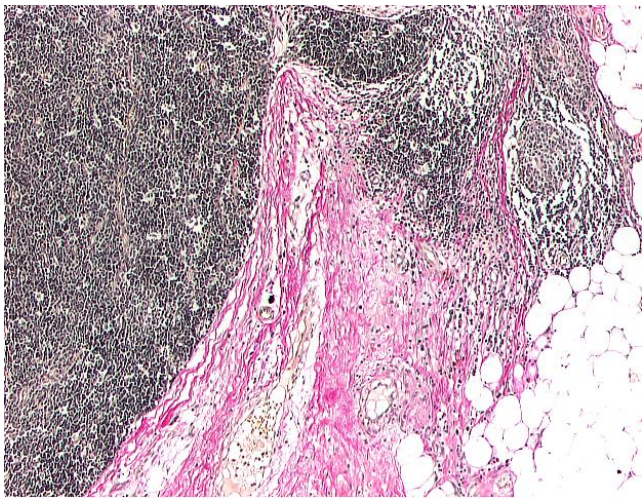

Fig. 5. AB thymoma with invasive capsular foci (Van Giesen staining)

DISCUSSION

Reports of extracardiac uptake and incidental diagnosis of mediastinal masses during ^{99m}Tc-tetrofosmin scintigraphy for the assessment of myocardial perfusion are present in the literature (1-4). Asian authors describe ^{99m}Tc-tetrofosmin scintigraphy as an useful investigation for thymus pathology, being able to detect mainly malignant tumors, tumor recurrences and metastatic lesions (5-7).

Although this investigation has not become a standard diagnostic for mediastinal tumors, it should be considered a valuable alternative when conventional investigations fail to confirm a clinical suspicion.

Thoracic CT scan has a reliable sensitivity and specificity and remains the method of choice in detecting thymus lesions. A limitation is the difficulty to differentiate thymus lymphoid hyperplasia and thymoma. On the other hand, thymus scintigraphy can distinguish after the degree of up-take of the radiotracer on the early and late images, between normal thymus, hyperplasia and thymoma.

Murakami and co-workers demonstrated the presence of thymus hyperplasia in Grave's disease patients, calculating the size and density of the thymus on untreated and treated Grave's disease patients, on CT scan images. They showed that thymus hyperplasia regresses in patients treated either with antithyroid drugs or total thyroidectomy (8).

The association of thymus hyperplasia with hyperthyroidism was reported by other authors that proven on biopsy that antithyroid treatment induces the remission of the thymus hyperplasia, avoiding such futile surgery (9).

Inoue et al reported a case of Graves' disease associated with a mediastinal mass with CT scan and MRI aspect suggestive for a thymoma. The patient underwent total thyroidectomy and thymectomy at the same stage. Pathology report showed a thymus hyperplasia (10).

Nakamura et al. demonstrated the pres-

ence of thyrotropine receptors in the hyperplasic thymus through mediastinal biopsy to a young patient with hyperthyroidism. The presence of these receptors raises the speculation that the thymus is also a target organ of the autoimmune aggression in Grave's disease (11).

Hyperthyroidism may be associated with thymus hyperplasia, in which no surgical action should be taken regarding the thymus, or with thymoma that requires surgical removal.

CONCLUSIONS

The association between thyroid and thymus lesions is challenging, both regarding diagnosis and therapy. Complementary imaging investigations such as thymus scintigraphy may prove helpful in decision making in certain cases.

FERULIC ACID: POTENTIAL THERAPEUTIC APPLICATIONS (Abstract): Ferulic acid is a phenolic compound that was first isolated in 1866 from the *Ferula foetida* resin (*Apiaceae* family) and was later obtained by synthesis. In nature, ferulic acid is found both in free and conjugated form. Due to its antioxidant effects ferulic acid can be used in the prevention and the therapy of diseases induced by oxidative stress, including Alzheimer's disease, diabetes mellitus, cancer, hypertension and atherosclerosis. The strong link between inflammation and oxidative stress suggests that ferulic acid can also be effective in the treatment of inflammatory conditions. Moreover, the specific ferulic acid structure also gives it a strong UV absorption capacity, making it a promising photoprotective agent. **Keywords:** FERULIC ACID, OXIDATIVE STRESS, ANTIOXIDANT, THERAPEUTIC EFFECTS.

Ferulic acid (4-hydroxy-3-methoxycinnamic acid) (fig. 1) was first isolated in 1866 from *Ferula foetida* (*Apiaceae* family) and synthesized in 1925 (1). The interest in ferulic acid dates to the 1970s when Japanese researchers discovered the antioxidant properties of its stearic acid esters, isolated from rice oil.

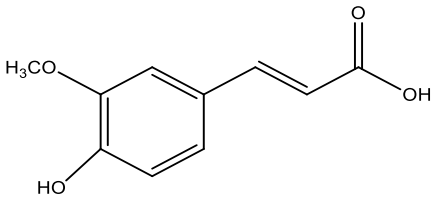

Fig. 1. Chemical structure of ferulic acid

Ferulic acid is found both in free form and as esters in vegetables, fruits, cereals and coffee. Among the richest sources of ferulic acid are wheat bran, citrus (orange juice), bananas, coffee, eggplants, cabbage, spinach, beets, bamboo shoots and broccoli (2, 3). In the western countries, extracts from various herbs, aromatics, spices represent other important sources of ferulic acid (1, 4).

It is estimated that by daily ingestion of foods of vegetable origin the intake of ferulic acid can reach 150-250 mg/day. Ferulic acid is absorbed through the gastrointestinal tract and is metabolized in the liver.

The aim of this study was to provide an outline of the different applications of ferulic acid in therapeutics, which will provide vast information to a wide range of researchers.

ANTIOXIDANT ACTIVITY

One of the most studied biological effects of ferulic acid is its antioxidant properties. Due to its phenolic nucleus and unsaturated side chain, the ferulic acid can readily form a resonance stabilized phenoxy radical which accounts for its effect of free radical removal (1). This allows ferulic acid to protect DNA and lipids from oxidation by reactive oxygen species (ROS). Ferulic acid and its derivatives exhibit antioxidant activity in response to free radicals (5, 6, 7). Given its antioxidant effects, ferulic acid may be beneficial in the prevention and treatment of disorders related to oxidative stress, including Alzheimer's disease, diabetes, cancer, hypertension and atherosclerosis (8). The strong link between inflammation and oxidative stress suggests that ferulic acid and its derivatives can also be effective in the treatment of inflammatory conditions (9, 10). Moreover, the specific ferulic acid structure also gives it a strong UV absorption capacity, making it a powerful skin protecting agent.

Based on the antioxidant effects of ferulic acid, Chinese researchers investigated the potential anti-atherosclerotic properties of ferulic acid (11). In the form of ferulate sodium salt, it is used in China for the treatment of cerebrovascular and cardiovascular diseases.

Ferulic acid at a dose of 150 mg/kg administered intraperitoneally (ip) for 4 days prevented lipid peroxidation and cellular apoptosis induced by free radicals in the Corti organ of guinea pigs exposed to noise (120 dB slp sound at a frequency of 6 kHz for 60 min). Interestingly, the administration of ferulic acid to these animals has reduced functional impairment and improved hearing function (12).

Antioxidant activity of ferulic acid appears to depend on the type of reactive species involved. In an experimental study which included rat brain microsomes, Trombino *et al.* (13) showed that ferulic acid had effectively inhibited lipid peroxidation activated by the peroxyl or peroxynitrite radical. This *in vitro* evidence agrees with the study by Kanski *et al.* (14) which demonstrated that the ferulic acid at a dose of 15-50 μM significantly attenuated cell death induced by the peroxyl radical from hippocampal neuronal cells.

Ferulic acid has been shown to influence secondary free radicals, such as those generated by carbon tetrachloride (CCl_4). Srinivasan *et al.*, showed that ferulic acid (20 mg/kg per os) prevents liver damage following CCl_4 administration in rat females. In this study, ferulic acid significantly reduced plasma liver toxicity markers as well as the protein and lipid oxidation marker levels (15).

THERAPEUTIC APPLICATIONS

Alzheimer's disease. Alzheimer's disease is a chronic neurodegenerative disorder characterized by progressive cognitive dysfunctions and memory loss (16, 17). The main role in the pathogenesis of this disease is the accumulation of beta-amyloid (βA), a peptide composed of 36-43 amino acids resulting from the amyloid precursor protein, by a proteolysis process under the action of β- and γ-secretases (18). Once produced, βA tends to aggregate in the form of oligomers or fibrils, thus forming

the core of the senile plaques. It is important to underline that βA activates specifically kinases such as glycogen synthase kinase 3 beta, cyclin-dependent kinase 5 and tyrosine-phosphorylated kinase 1A, which are responsible for hyperphosphorylation of tau protein and aggregation into neurofibrillary aggregates (19). The accumulation of oligomers, which precedes the formation of tau protein aggregates, results in an abnormal increase in ROS concentration, such as superoxide anion and hydrogen peroxide (19). There is also type 1 tumor necrosis factor alpha receptor activation, which, in the presence of apoptotic protease activator factor 1, activates the apoptosis cascade (20). It has been proven that an increased amount of βA diminishes the activity of superoxide dismutases (SOD-1 and SOD-2), leading to elevated intracellular ROS levels, which ultimately causes oxidative damage to lipids and neuronal proteins (20). At the same time, the superoxide anion (O^{2-}) excess reacts with nitrogen monoxide (NO) produced by activating microglial cells with peroxynitrite and other reactive nitrogen species (RNS) involved in protein nitration (21). The accumulation of ROS/RNS together with the activation of apoptosis and decreased SOD activity contributes to the destruction of cholinergic areas involved in cognitive performance, such as amygdala, hippocampus and cortex (22). Ferulic acid, through its antioxidant and anti-inflammatory properties, can have beneficial effects in Alzheimer's disease (23).

In adult rats, dietary supplementation with sodium ferulate (100-200 mg/kg bodyweight) for 4 weeks counteracted the increase of age-induced pro-inflammatory cytokines such as interleukin-1β (IL-1β) and helped to prevent the reduction of protein-serine/threonine kinase and protein kinase B with an important neuroprotective role in the rat hippocampus (24).

The neurotropic and neuroprotective effects of ferulic acid have also been demonstrated in the case of short-term parenteral administration. Mamiya T *et al.* (25) demonstrated that ferulic acid (5 mg/kg) administrated subcutaneously in mice for 6 days reduced brain damage due to the induction of oxidative stress by lowering the glutathione concentration and significantly increased cognitive activity.

Neoplastic Disorders. There are several factors involved in the pathogenesis of cancer, including chronic inflammation, excessive cell proliferation and/or apoptosis resistance and free radical formation. As a result, there is DNA and cellular protein damage and abnormal activation of the enzymes involved in the synthesis of proinflammatory mediators, respectively the activation of cyclooxygenase (COX) and nitric oxide synthase (NOS). From this perspective, each of these factors plays an essential role in carcinogenesis, amplifying the cascade of cell proliferation (26). The proven ability of ferulic acid to regulate cell proliferation and growth, to remove free radicals, to stimulate cytoprotective enzymes and to inhibit cytotoxic systems in both *in vitro* and *in vivo* experimental models supports the potential adjuvant role of ferulic acid in cancer therapy (27).

On colon cancer cells ferulic acid exhibited antiproliferative effects (28). The effect is due to the positive regulation of genes that encode the proteins involved in centrosome formation, of the gene for SMC1L1 protein that controls the S phase of the cell cycle as well as the negative regulation of genes involved in coding for

cyclin A2 kinase, cyclin B1 kinase, transcription factor and ornithine decarboxylase, respectively.

Nicotine plays an essential role in the pathogenesis of lung cancer by increasing the concentration of free radicals in many cell types, including leukocytes. Ferulic acid, at 10-40 mg/kg orally administered for 22 weeks, significantly reduced plasma lactate dehydrogenase and alkaline phosphatase in nicotine-treated rats. In a concentration of 100-150 μM, ferulic acid prevented nicotine-induced lipid peroxidation and DNA damage, respectively, and increased intracellular levels of SOD, catalase (CAT) and vitamin A, C and E in rat lymphocytes. It is important to point out that ferulic acid has not caused any DNA damage (29).

Another possible target of ferulic acid derivatives is cyclooxygenase (COX), which exists in the form of two major isoforms, COX-1 and COX-2. In various cancers, cyclooxygenase, the COX-2 form, is known to have superior regulation, which has led to the consideration of nonsteroidal anti-inflammatory drugs as potential anticancer drugs. Octyl-ferulic and dodecyl-ferulic esters significantly reduced the development of tumor cells in the central nervous system, colon, lungs and breasts. The half maximal inhibitory concentration (IC50) ranged from 17.05 mg/mL in breast cancer cells to 4.29 mg/mL in colon cancer cells (30). In addition, ferulic acid esters inhibited COX-2 activity, although this effect was not strictly selective and significantly decreased in esters with chain length greater than C8.

Administration of ferulic acid (40 mg/kg orally) or *Ixora javanica* extract (200 mg/kg orally), the active compound of which was identified as ferulic acid, in 7, 12-dimethylbenz[a]anthracene and methylcholanthrene-induced breast carcinogenesis demonstrated a decrease in tumor formation in rodents. The mechanisms involved in these antiproliferative effects can be associated with the antioxidant activity of ferulic acid and with the modulating effect on phase II antioxidant enzymes (31). In addition, ferulic acid reduced the development of sarcoma-180 and Ehrlich ascites carcinoma induced in mice, thus increasing the survival rate of experimental animals. Also, ferulic acid administered to rats in food at a concentration of approximately 500 mg/kg per meal for 7 weeks, significantly reduced the incidence of neoplasms, of cutaneous squamous cell papilloma and of preneoplastic lesions (hyperplasia and dysplasia) until 32 weeks (31).

Preclinical evidences have suggested that ferulic acid has potential for use as adjuvant in chemotherapy and radiotherapy. On the HeLa human cervical cancer cell line and keratinocyte cell k562, ferulic acid potentiated the cytotoxicity of platinum-based neoplastic agents (carboplatin and cisplatin) and 5-fluorouracil. Ferulic acid has been found to inhibit the growth of HeLa cells having an IC50 of 320M what is M??? (32). Furthermore, ferulic acid potentiated the effect of radiotherapy on HeLa and lung cancer cells (33).

Cardiovascular diseases. Cardiovascular diseases worldwide are associated with a high mortality rate. Hypertension and atherosclerosis are the main risk factors in the development of cardiovascular disease and, consequently, blood pressure control is particularly important in reducing the incidence of these diseases (34).

Ferulic acid (1-100 mg/kg orally) lowered blood pressure both in rat primary hypertension and in rats with genetic hy-

pertension, varying with the administered dose. It was noted that 50 mg/kg of chronic treatment with ferulic acid resulted in an antihypertensive effect comparable to that obtained with 10 mg/kg captopril. Ferulic acid reduced left ventricular diastolic rigidity, attenuated the infiltration of inflammatory cells and the collagen deposition in the left ventricle (35).

The vasodilator effect of ferulic acid has multiple valences since it involves the reduction of angiotensin II, the increase of NO synthesis and finally the reduction of NADPH-dependent peroxide anion synthesis (36).

Ferulic acid consumption (9.5 mg/kg orally) reduced triglycerides in rats and rabbits and cholesterol levels in rats. In a fat-rich diet, these lipid-lowering effects led to a significant decrease in the atherosclerotic area of the rabbit aorta and improved endothelial function (37).

Ferulic acid 0.6 mg/kg administration by intravenous bolus in rat myocardial ischemia-induced cardiac arrhythmias delayed early ventricular contractions, decreased duration of ventricular tachycardia and ventricular fibrillation, resulting in reduced mortality rate (38).

In a clinical study Wang *et al.* (39) have shown that ferulic acid as sodium salt has therapeutic potential in angina pectoris and coronary artery disease. Sodium ferulate (200-300 mg/day) administered for 2 weeks potentiated the therapeutic effects of nitrates, β-blockers, calcium channel blockers by the significant reduction in the incidence of angina attacks, reduction of nitroglycerin dose, along with an improvement in cardiac function tests. In subjects which did not respond to nitrates or β-blocker therapy, the intravenous administration of ferulic acid alone improved clinical symptoms and symptoms relief (39).

Recent studies on vascular smooth muscle cells isolated from rat thoracic aorta revealed that sodium ferulate might improve vascular functions and reduce restenosis after coronary interventions by inhibiting the neointimal hyperplasia (40).

Diabetes mellitus. Diabetes mellitus is a chronic disease characterized by the reduction of insulin synthesis and by the increased resistance of peripheral tissues to endogenous hormone in varying degrees. Increased blood glucose level affects many of the body cells, especially blood vessels and nerves. In addition, hyperglycemia is also responsible for the excess production of ROS, through the mitochondrial electron transport chain, which plays a significant role in the pathophysiology of cellular dysfunction and complications of diabetes (41).

In diabetic models on animals, ferulic acid has produced beneficial effects acting on several levels. Ferulic acid eliminates free radicals and activates antioxidant enzymes, thus reducing cellular redox imbalance. In mice with aloxan-induced or streptozotocin-induced diabetes, oral administration of 10-50 mg/kg ferulic acid demonstrated antioxidant activity, reduction of lipid peroxidation markers, stimulation of cellular response, and reduction of NF-κB immunoreactivity in pancreas, liver, kidneys and serum (42).

In streptozotocin-induced diabetic rats, ferulic acid (10 and 40 mg/kg per os) given for 3 weeks reduced blood glucose levels. This observation confirms the results obtained by Jung *et al.* (43), which demonstrated that oral administration of ferulic acid for 17 days in diabetes mellitus induced in mice increased insulin plasma concentration and reduced glucose in the blood. At the same time, the study revealed

that ferulic acid stimulates both liver glycogen synthesis and increases glucokinase activity, a key enzyme in regulating blood glucose levels. Ferulic acid also inhibits rat intestinal sucrase and maltase, acting as a natural inhibitor of alpha-glucosidase (43).

In diabetic patients, nephropathy and hypertension are some of the most common complications. The pathogenesis of these complications involves a multitude of factors including the renin-angiotensin system, activation of protein kinase C and acceleration of oxidative stress. In obese rats with induced type 2 diabetes ferulic acid (10 mg/kg/day for 20 weeks or 0.2% for 12 weeks orally) significantly reduced proteinuria level, oxidative stress marker concentration as well as expression of cytokine, diminished glomerular membrane thickness and glomerular volume compared to control group (44).

Photoprotection. On dermal application, ferulic acid has a good absorption, both at neutral and acid pH, demonstrating that the molecule can be absorbed through the skin in both dissociated and undissociated form. In healthy subjects, ferulic acid in the form of a saturated aqueous solution, pH 7.2, applied locally, has been shown to be effective in protecting skin tissue against UV light-induced erythema. The photoprotective effect of ferulic acid (0.5%) was enhanced by the combination with vitamin C (15%) and vitamin E (1%), formulation which applied locally in pigs experimentally exposed to UV radiation gave good results (45, 46).

Ferulic acid can be expected to have photoprotective effect when orally administered.

CONCLUSIONS

Our study revealed that ferulic acid and its derivatives prove to be very good antioxidants that can be used to prevent several diseases (Alzheimer's disease, neoplastic diseases, cardiovascular diseases, diabetes mellitus), and for photoprotection with a high safety profile and low financial costs. Some of the presented compounds promise wider practical applications in therapy, but clinical trials are still needed.

2. Disciplina de Biochimie

THE EFFECTS OF BRANCHED CHAIN AMINOACIDS ON HDL-CHOLESTEROL IN EXPERIMENTAL ANIMALS SUBJECTED TO DIETARY HYPERCHOLESTEROLEMIA (Abstract): High levels of high-density lipoprotein cholesterol (HDL) are associated with a reduced risk of cardiovascular disease, so that many studies focus on modify HDL levels for therapeutic purpose. **Aim:** The present research aims to highlight changes in plasma levels of HDL-cholesterol in experimental animals with a high-fat diet associated with some branched aminoacids - valine and leucine. **Material and methods:** The experiment was realised on 32 male Wistar rats, which were divided in four groups: group I- received a standard diet; group II – was fed with cholesterol (C), group III (C + V) - cholesterol and valine and group IV (C + L) - cholesterol and leucine. After 8 weeks animals were evaluated in relation with lipids levels in the blood. **Results:** The average values of HDL-cholesterol in group who received only cholesterol (C) were significantly lower compared with group III who received cholesterol and valine (C + V) or group IV that received cholesterol and leucine (C + L) ($p<0.001$), after one month and at the end of the experiment. **Conclusions:** Our results showed that valine and leucine increased the serum levels of HDL-cholesterol and therefore they are useful components in coronary artery disease risk reduction. The association of these aminoacids in human diets can improve clinical conditions associated with hyperlipidaemia such as atherosclerosis. **Key words**: BRANCHED AMINOACIDS, HDL-CHOLESTEROL, HYPERCHOLESTEROLEMIA, ATHEROSCLEROSIS.

Un număr considerabil de studii epidemiologice şi populaţionale au raportat că valori crescute ale HDL-colesterolului par a întârzia sau împiedica dezvoltarea aterosclerozei în timp ce niveluri reduse sunt asociate cu un risc crescut de apariţie a acestei afecţiuni (1,2). De asemenea, nivelul lipidelor sanguine, în special al colesterolului total şi al LDL-colesterolului, sunt de obicei legate de promovarea aterosclerozei, prin urmare, unele măsuri care scad nivelurile de lipide pot întârzia sau inversa progresia acestor procese.

Identificarea factorilor de risc implicaţi în apariţia aterosclerozei şi modularea factorilor cu rol protector în scopul unor acţiuni ţintite de prevenţie sau instituirii unor atitudini terapeutice care să amelioreze sau să întârzie bolile vasculare şi complicaţiile acestora constituie obiective de mare importanţă ale cercetării medicale actuale (3,4). Abordările existente sunt limitate în

capacitatea lor de a creşte HDL-colesterolul, care continuă să fie un obiectiv major în dezvoltarea de noi terapii, fie de creştere a HDL-colesterolului, fie de îmbunătăţire a funcţiei acestuia.

Studii recente abordează relaţia dintre aminoacizi şi diferite sisteme din organismul uman, subliniind rolul din ce în ce mai mare al acestor compuşi.

MATERIAL ŞI METODE

Am efectuat un studiu experimental pe un număr de 32 de şobolani Wistar masculi, cu greutatea între 250-280 g. Durata experimentului a fost de 8 săptămâni. Animalele au fost distribuite în 3 loturi a câte 8 şobolani: lot I – martor - a primit dietă standard; lotul II –a primit dietă suplimentată cu colesterol în doză de 0,4g/kg c/zi (C); lotul III –a primit dietă suplimentată cu colesterol în doză de 0,4g/kg c/zi şi cu aminoacidul valină în doză de 62,5mg/kg c/zi (C+V); lotul IV - a primit colesterol în doză de 0,4g/kg c/zi şi aminoacidul leucină în doză de 69,985mg/kg c/zi (C+L).

Pentru urmărirea nivelelor serice ale parametrilor lipidelor sanguine, la începutul experimentului, la 30 de zile şi la sfârşitul experimentului s-au recoltat probe de sânge din plexul retroorbitar de la fiecare şobolan. Anterior recoltării probelor s-a efectuat anestezia animalelor cu ketamină – 75 mg/kg intraperitoneal. Procedeele experimentale folosite în acest studiu au fost în concordanţă cu reglementările etice internaţionale. Rezultatele obţinute au fost centralizate în baze de date EXCEL şi SPSS şi prelucrate cu funcţii statistice adecvate.

Cercetarea de faţă îşi propune să evidenţieze doar efectele administrării aminoacizilor cu catenă ramificată – valină şi leucină - asupra nivelului HDL - colesterolului seric, urmând ca rezultatele cu privire la ceilalţi parametri lipidici să fie prezentate în articole viitoare.

REZULTATE

Pentru fiecare lot în parte, HDL-colesterolul a fost investigat în trei momente: la începutul experimentului - R0, după 1 lună - R1 şi la finalul experimentului - R2. Evoluţia valorilor HDL-colesterolului pe tot parcursul experimentului, precum şi varianţa seriilor de valori ale acestui parametru au fost în permanenţă raportate la lotul martor (tab.I, fig.1).

TABELUL I

Valori ale HDL-colesterolului înregistrate la loturile de studiu

Lot	R0	R1	R2
Lot I: Martor			
media	23.00	22.89	22.90
SD	1.49	1.22	1.68
CV%	6.47	**5.34**	7.35
Lot II: C			
media	22.44	19.45	15.94
SD	3.29	1.45	1.20
CV%	**14.67**	**7.47**	7.54
Lot III: C+V			
media	22.98	24.65	26.86
SD	1.48	2.79	2.95
CV%	**6.44**	11.34	11.00
Lot IV: C+L			
media	22.51	22.98	23.18
SD	2.16	1.90	1.81
CV%	9.59	8.27	**7.83**

La lotul martor, coeficientul de variație cel mai mic s-a înregistrat la 1 lună de la debutul experimentului (5,34 CV%). Varianța seriilor de valori la lotul II, III şi IV este redusă, variind de la 6,44 la 14,67 CV%, însă cele mai omogene serii de valori se observă la începutul experimentului la lotul III C+V (6,44 CV%), după 1 lună la lotul II - C (7,47 CV%), iar la sfârşitul experimentului la lotul IV - C+L (7,83 CV%). Cele mai mici valori individuale ale HDL-colesterolului se regăsesc la lotul II care primeşte numai colesterol (fig. 1).

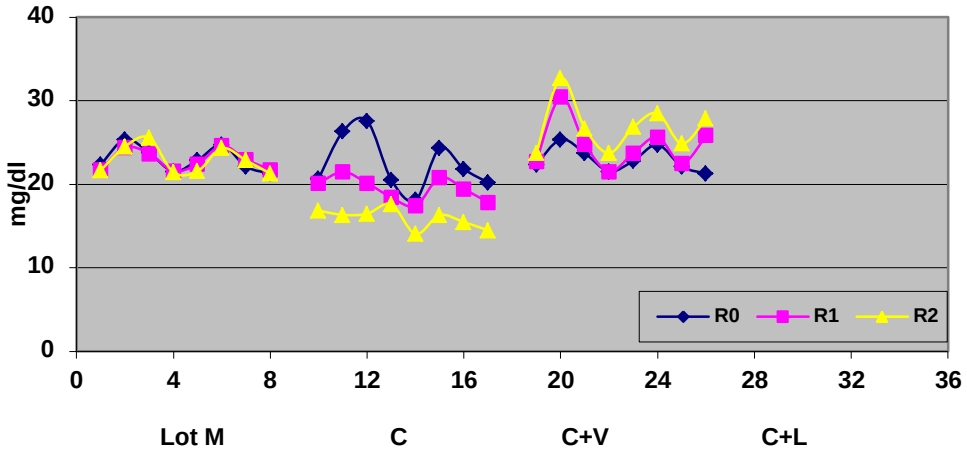

Fig. 1. Valori individuale ale HDL-colesterolului evidențiate la loturile de studiu

Valorile medii ale HDL-colesterolului la loturile II, III şi IV, în funcție de momentul investigării prezintă următoarele diferențe procentuale (fig. 2):

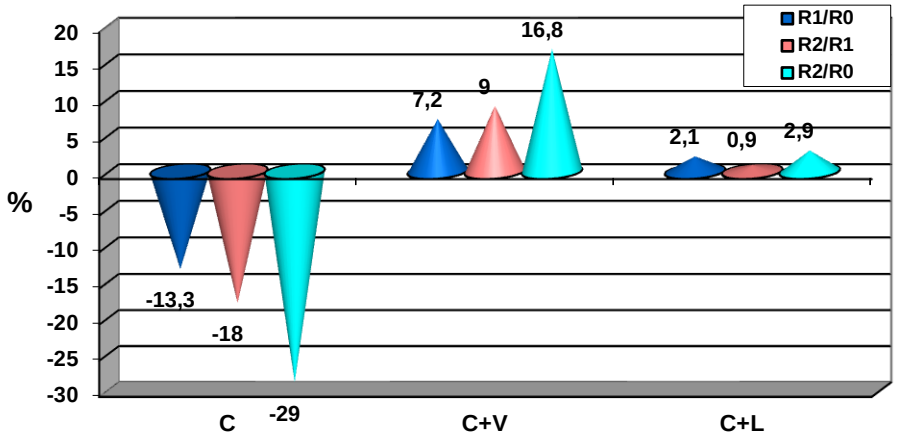

Fig. 2. Diferența procentuală a valorilor medii ale HDL-colesterolului la loturile II, III şi IV față de debutul studiului

La lotul II - C, s-a evidenţiat o scădere procentuală a valorilor medii ale HDL-colesterolului de 13,3% după 1 lună, iar la sfârşitul experimentului comparativ cu momentul iniţial, scăderea a fost de 29%; la lotul III - C+V s-a observat o creşterea procentuală a valorilor medii ale HDL-colesterolului de 7,2 % la 1 lună, iar la sfârşitul experimentului de 16,8%; la lotul IV - C+L, creşterea procentuală a valorilor medii ale HDL-colesterolului a fost de 2,1% la 1 lună, iar la sfârşitul experimentului de 2,9%.

La debutul studiului nu s-au înregistrat diferenţe semnificative între valorile medii ale HDL-colesterolului la loturile II, III şi IV şi nici între acestea şi lotul martor ($p>0,05$). Comparativ cu martorii, la 1 lună de la debutul experimentului, valorile medii ale HDL-colesterolului au fost semnificativ mai mici la lotul II- C ($p<0,001$) şi semnificativ mai mari la lotul III - C+V ($p<0,01$), la sfârşitul experimentului. Valorile medii ale HDL-colesterolului la lotul II au fost semnificativ mai mici comparativ cu lotul III sau cu lotul IV ($p < 0,001$), atât după o lună de experiment, cât şi la sfârşitul experimentului. La final, lotul IV a avut valori medii ale HDL-colesterolului semnificativ mai mici decât lotul III ($p<0,01$) (tab.II, fig. 3).

TABELUL II

Diferenţe statistice între valorile medii ale HDL-colesterolului la loturile de studiu

Moment	Lot	Lot M (n=8)	C (n=8)	C+V (n=8)
R0	C (n=8)	t = 0,44 p > 0,05	-	
	C+V (n=8)	t = 0,03 p > 0,05	t = 0,44 p > 0,05	-
	C+L (n=8)	t = 0,53 p > 0,05	t = 0,05 p > 0,05	t = 0,51 p > 0,05
R1	C (n=8)	t = 5,15 **p < 0,001**	-	
	C+V (n=8)	t = 1,63 p > 0,05	t = 4,69 **p < 0,001**	-
	C+L (n=8)	t = 0,11 p > 0,05	t = 4,19 **p < 0,001**	t = 0,28 p > 0,05
R2	C (n=8)	t = 9,54 **p < 0,001**	-	
	C+V (n=8)	t = 3,30 **p < 0,01**	t = 9,70 **p < 0,001**	-
	C+L (n=8)	t = 0,32 p > 0,05	t = 9,43 **p < 0,001**	t = 3,01 **p < 0,01**

DISCUȚII

Relația dintre hipercolesterolemie şi procesul aterosclerotic a fost de-a lungul timpului în atenția a numeroase cercetări morfologice şi experimentale. Colesterolul şi trigliceridele sunt lipidele sanguine de cel mai mare interes pentru ateroscleroză şi cardiopatia ischemică (5), dar numeroase studii epidemiologice indică de asemenea o corelație indirectă puternică între concentrațiile plasmatice ale lipoproteinelor cu densitate mare (HDL) şi bolile cardiovasculare. Din colesterolul seric total, componenta majoră asociată cu un risc crescut este LDL-colesterolul, care are un rol fiziologic esențial în furnizarea colesterolului țesuturilor periferice (6,7). În contrast, HDL-colesterolul are rolul de a mobiliza colesterolul din ateroamele în formare sau din cele deja formate şi a-l transporta la ficat pentru a fi excretat în bilă. Pe lângă abilitatea de a îndepărta colesterolul de la nivel celular, HDL-colesterolul are proprietăți antiinflamatorii, antioxidante şi antitrombotice, care contribuie la îmbunătățirea funcției endoteliale şi inhibiția aterosclerozei (8). Astfel, cu cât nivelul HDL-colesterolului este mai crescut, cu atât riscul apariției aterosclerozei este mai scăzut şi, prin urmare, este de înțeles interesul special pentru dietele, medicamentele şi obiceiurile comportamentale de reducere a LDL-ului seric şi creştere a HDL-ului seric (9,10).

Tratamente care cresc HDL-ul s-au dovedit a fi eficace în reducerea incidenței bolilor cardiovasculare, atât în prevenția primară cât şi secundară, deşi nu este complet definită dovada că o creştere a HDL-colesterolului printr-un tratament farmacologic este în măsură să confere o reducere a riscurilor majore cardiovasculare independent de modificări ale LDL-ului sau de nivelurile de trigliceride (11). În diferite

modele experimentale, restricţia în carbohidraţi s-a dovedit a fi eficientă în reducerea trigliceridelor plasmatice, creşterea HDL-colesterolului şi modificarea repartiţiei subfracţiilor LDL-colesterolului (12). Atât HDL, cât şi exerciţiile fizice s-au dovedit a fi factori predictori pentru bolile cardiovasculare, în special pentru boală cardiacă coronariană. Creşterea efortului fizic este asociată cu creşterea HDL explicând în parte efectul benefic asupra HDL (13).

Dietele bogate în colesterol şi grăsimi saturate, cum ar fi cele prezente în gălbenuşul de ou, grăsimi animale şi unt, cresc nivelul colesterolului plasmatic, în timp ce dietele sărace în colesterol şi grăsimi polinesaturate îl reduc (14). Mai mult decât atât, acizii graşi omega-3, prezenţi în cantitate crescută în uleiul de peşte, sunt probabil benefici, în timp ce grăsimile nesaturate produse prin hidrogenarea artificială a grăsimilor vegetale polinesaturate şi utilizate în alimentaţie pot afecta nefavorabil profilele de colesterol, conducând la ateroscleroză. Medicamentele numite *statine* reduc colesterolul circulant indirect, prin inhibarea HMGCoA-reductazei, o enzimă cheie necesară pentru biosinteza colesterolului în ficat (15,16).

În cercetarea noastră se remarcă o scădere a valorilor HDL prin administrarea dietei bogată în colesterol faţă de animalele cu dietă standard din lotul martor ceea ce arată o diminuare a capacităţii de transport al colesterolului de la nivel vascular la nivel hepatic, conform şi altor date din literatură(8,9,10).

De-a lungul timpului au fost realizate diferite studii care au ajutat la descifrarea deprecierii metabolice care implică carbohidraţii şi acizii graşi în afecţiunile cardiace. La polul opus se află datele relativ puţine despre potenţialul impact al aminoacizilor în derularea acestor boli. Deşi majoritatea activităţilor catabolice ale aminoacizilor se desfăşoară în ficat, catabolismul aminoacizilor cu catenă ramificată (BCAA) necesită o activitate în mai multe ţesuturi nonhepatice, inclusiv muşchiul cardiac, diafragm, creier şi rinichi. O atenţie deosebită a fost acordată în ultimul timp unor modele genetice recent dezvoltate legate de defecte ale catabolismului BCAA cu impact în fiziopatologia cardiacă (17). Studii experimentale au arătat că deficitul de valină sau izoleucină are efecte similare asupra reducerii masei de ţesut adipos, într-un mod similar cu cele observate în timpul privării de leucină. Animalele hrănite cu o dietă deficitară în aceşti aminoacizi prezintă modificări semnificative ale metabolismului lipidic, fapt demonstrat de suprimarea lipogenezei în ficat şi creşterea mobilizării grăsimilor din ţesutul adipos alb (18).

CONCLUZII

Studiul biochimic a relevat, prin compararea parametrilor metabolismului lipidic în grupurile diferite conform design-ului experimentului, faptul că aminoacizii esenţiali tip valină şi leucină au un efect direct asupra hipercolesterolemiei prin creşterea HDL-colesterolului plasmatic. Consecutiv, endoteliul vascular este protejat, cu diminuarea riscului de apariţie a disfuncţiei endoteliale şi prin urmare a unor afecţiuni cardiovasculare care au ca mecanism patogenetic această perturbare. Aminoacizii cu catenă ramificată tip valină şi leucină pot fi utili astfel pentru tratamentul profilactic sau terapeutic al unor condiţii clinice asociate cu hiperlipidemie, cum ar fi ateroscleroza.

THE IMPACT OF OXIDATIVE STRESS ON MYOCARDIAL REPERFUSION: ALTERNATIVE EVIDENCE (Abstract): **Aim:** Our study aimed to investigate the impact of oxidative stress on myocardial reperfusion phenomenon. Since obtaining morphological evidence of oxidative stress is practically impossible in vivo, we used as "surrogate" evidence the primary percutaneous transluminal coronary angioplasty effects. **Material and methods**: The study group consisted of 22 patients hospitalized with a diagnosis of acute myocardial infarction with ST segment elevation in the Institute of Cardiovascular Diseases "Prof. Dr. George I. M. Georgescu" Iasi. Patients were evaluated by coronary angiography. To restore myocardial reperfusion we applied primary percutaneous transluminal coronary angioplasty. Evidence resume coronary flow by primary percutaneous transluminal coronary angioplasty were assessed by: (1) Thrombolysis in Myocardial Infarction (TIMI) flow, Myocardial *Blush* Grade (MBG) and complications as no-reflow, distal emboli; (2) evolution of the electrocardiographic changes. **Results**: Evaluation of myocardial blood flow resumption revealed, as final results, TIMI 3 flow with MBG 2-3 and without *no-reflow* in 21 cases. A single case has shown signs of irreversible *no-reflow*. Analysis of evolutionary electrocardiographic changes (ST segment elevation, depression) allowed assessment of the effectiveness of interventional reperfusion, dependent on the time of presentation and independent of the culprit artery patency. **Conclusions**: Assessment of myocardial reperfusion by alternative evidence provides a range of information how to restore the functional integrity of myocardium, but without allowing an analysis of biochemical and morphological substrate of the evolution of lesions, in terms of oxidative stress intervention. Studies of the dynamics of oxidative stress-induced changes at the structural level impose, under the peculiarities of myocardium, the design of an experimental model. **Key words:** OXIDATIVE STRESS, MYOCARDIAL REPERFUSION, NO-REFLOW

Stresul oxidativ reprezintă fenomenul în care există exces de radicali liberi ca urmare a excesul de sinteză a lor şi/sau prin deficitul mecanismelor de protecţie contra acestora. Acest fenomen induce anomalii biochimice, metabolice şi funcţionale (1). Are contribuţii semnificative în multe procese patologice, inclusiv în boala ischemică cardiacă şi reperfuzia miocardică. În reperfuzia miocardică este interesat şi peretele vascular, astfel încât este alterată funcţia endotelială ca urmare a modificărilor metabolice profunde

generate de formarea în exces de radicali liberi odată cu reintroducerea brutală a oxigenului molecular (2). Leziunea de reperfuzie implică astfel stres oxidativ ca urmare a excesului de radicali liberi ce apare odată cu reintroducerea bruscă a oxigenului molecular, şi deficitul mecanismelor antioxidante endogene, fie ca urmare a depăşirii acestora prin exces de radicali liberi, fie prin deficitul primar al lor ca urmare a ischemiei ce a precedat reperfuzia (3).

Tratamentul de reperfuzie miocardică aplicat în infarctul miocardic acut cu supradenivelare de segment ST reprezintă tehnica de aur în tratamentul acestei patologii, în scopul salvării miocardului la risc, şi în acest mod, de menţinere a funcţiei de pompă a inimii şi de prevenire a complicaţiilor pe termen scurt şi la distanţă (4). Obiectivul principal este reprezentat de restaurarea perfuziei tisulare, la nivel microvascular. Metodele de reperfuzie miocardică, denumite în practica clinică revascularizare, sunt reprezentate de tromboliză, angioplastie coronariană percutană transluminală (ACPT) primară, şi pontaj aorto-coronarian. ACPT primară este superioară trombolizei în ceea ce priveşte restaurarea imediată a fluxului coronarian normal, scăderea riscului de ischemie recurentă şi reinfarct, cu beneficii mai mari la grupele de pacienţi cu risc crescut, şi cu efect mai durabil (5, 6, 7).

Obţinerea unor dovezi morfologice asupra impactului stresului oxidativ in fenomenul de reperfuzie miocardică este practic imposibilă *in vivo*. În acest context, studiul nostru analizează un set de dovezi "surogat" care permit evaluarea eficacităţii fenomenului de reperfuzie miocardică, inclusiv la nivelul microcirculaţiei, prin angioplastie coronariană percutană transluminală primară.

MATERIAL ŞI METODE

Lotul de studiu a fost format din 22 de pacienţi (19 de sex masculin, 3 de sex feminin), cu vârste cuprinse între 33 şi 81 de ani, internaţi cu diagnosticul de infarct miocardic acut cu supradenivelare de segment ST (IMA) în Institutul de Boli Cardiovasculare "Prof. Dr. George I. M. Georgescu" Iaşi. Au fost incluşi pacienţii cu durere toracică persistentă şi cu supradenivelare persistentă de segment ST sau cu bloc de ram nou apărut, în primele 12 ore de la debutul infarctului, conform cu indicaţia de clasă I a liniilor ghid cele mai recente ale Societăţilor Americană şi Europeană de Cardiologie, adaptate şi aplicate de către Societatea Română de Cardiologie (4, 8, 9, 10).

La aceşti pacienţi am realizat angiografie coronariană urmărind artera responsabilă de IMA, patenţa sa, prezenţa colaterale-lor, prezenţa altor leziuni coronariene si, ulterior, am aplicat protocolul de angioplastie coronariană percutană transluminală primară (11).

Procedura invazivă a constat în aspirarea trombului şi implantare de stent metalic sau farmacologic activ. În raport cu debutul simptomatologiei, procedura a fost aplicată, pentru 14 cazuri, în primele 6 ore (aplicare precoce), iar pentru celelalte 8 cazuri, într-un interval de 6-12 ore (aplicare tardivă).

Dovezile reluării fluxului coronarian prin angioplastie coronariană percutană transluminală primară au fost apreciate prin: (1) evaluarea fluxul TIMI (Thrombolysis in Myocardial Infarction), "*blush*" miocardic-MBG (Myocardial *Blush* Grade) şi a prezenţei complicaţiilor de tip no-reflow, emboli distali (12); (2) evaluarea evoluţiei modificărilor electrocardiografice (13, 14, 15).

REZULTATE

Evaluarea circulației coronariene

Coronarografia efectuată în urgență a relevat următoarele aspecte. În 16 cazuri, ocluzie trombotică acută a arterei responsabile de IMA. În două dintre aceste 16 cazuri au fost prezente colaterale. 8 pacienți au prezentat afectare unicoronariană, iar ceilalți 8 – afectare bi- sau tricoronariană. În 6 cazuri, a fost evidențiată o arteră responsabilă de infarct patentă, cu sau fără tromb, dar cu leziune critică, 1 caz prezentând flux distal TIMI 1 pe fondul unor leziuni tricoronariene cu stenoză critică a trunchiului principal al arterei coronare stângi. Nici unul dintre cele 6 cazuri nu a prezentat colaterale, afectarea a fost unicoronariană în 3 cazuri şi bi- sau tricoronariană în celelalte 3 cazuri.

Elemente de evoluție ulterioară ACPT primare

a) Dovezi alternative ale reluării fluxului coronarian prin ACTP primară: flux TIMI, *blush* miocardic-MBG, *no-reflow*, emboli.

Evaluarea reluării circulației sanguine miocardice a evidențiat, ca rezultate finale, flux TIMI 3 cu *blush* miocardic (MBG 2-3) şi fără *no-reflow* în 21 cazuri (95,45%), cu următoarele particularități:

- 18 cazuri, la care protocolul ACPT a fost aplicat fără incidente intervenționale, au avut o evoluție clinică foarte bună, cu dispariția imediată a durerii, sau diminuarea sa importantă şi cu dispariție ulterioară, fără complicații, fiind considerate ca reperfuzie eficientă;

- 2 cazuri au prezentat embolii distale în artera descendentă anterioară (ADA) apical, dar evoluția a fost favorabilă;

- un caz a evoluat cu obținerea unui flux inițial TIMI 1 fără *blush* (*no-reflow*) şi ulterior, după administrare intracoronariană de adenozină, nitroglicerină şi ser fiziologic cald, cu flux TIMI 3 şi cu *blush*; această situație a fost încadrată ca fenomen de *no-reflow* reversibil terapeutic, evoluția pacientei fiind in final excelentă.

Un singur caz, diagnosticat cu ADA cu stenoză ostială 70-80% şi ocluzie ADA în segmentul I (bicoronarian), a prezentat flux distal TIMI 1 fără *blush*. Toate manevrele aplicate nu au condus la o îmbunătățire a fluxului, situația fiind încadrată ca fenomen de *no-reflow* ireversibil, cu evoluție nefavorabilă.

b) Dovezi alternative ale reluării fluxului coronarian prin ACTP primară: evoluția modificărilor electrocardiografice

Rezultatele analizei modificărilor electrocardiografice evolutive, cu referire la rezoluția supradenivelării de segment ST, ca indicator al reluării fluxului coronarian, sunt prezentate în tabelul I.

Caracteristicile electrocardiografice evolutive, analizate la 12 din cei 14 pacienți pentru care ACPT primară a fost practicată precoce (în primele 6 ore) au evidențiat:

- rezoluția completă a sumST (suma supradenivelărilor de segment ST din toate derivațiile) pentru supradenivelare, considerată la ≥ 70%, la 4 pacienți, iar pentru subdenivelare la 2 pacienți, dintre care doar unul se încadra la rezoluția completă a supradenivelării; dintre aceştia, doar unul a prezentat arteră patentă;

- rezoluție parțială a sumST pentru supradenivelare, considerată între 30-70%, la 8 pacienți, 3 prezentând arteră patentă;

- rezoluția slST (supradenivelarea de segment ST dintr-o singură derivație – "single lead") completă (considerată ≥ 70%) la 3 pacienți, parțială (considerată între 50-70% pentru IMA anterioare şi între 20-70% pentru cele inferioare) la 9 pacienți.

TABELUL I

Evoluția modificărilor electrocardiografice

(* indică pacienții cu arteră patentă la prezentare)

Caz	Timp (ore)	Segment ST supr_deniv (mm)	SumST supr_deniv (%)	SumST sub_deniv (%)	slST	Segment ST supr_deniv (mm) max (60 min postACTP)
1	5	6	64 %	90 %	67 %	2
2*	2,5	3	30 %	absentă	33 %	2
3	6	5	78 %	absentă	60 %	2
4*	4	absentă	-	absentă	-	Absentă
5	3	2	75 %	absentă	50 %	1
6	8	2	63 %	43 %	33 %	0,5
7*	2	5	50%	absentă	40 %	2
8	1	6	50 %	absentă	50 %	3
9*	3	2,5	60%	absentă	60 %	1,5
10	7	6	40 %	63 %	50 %	3
11*	1	2	70 %	81 %	67 %	1
12	12	5	60%	absentă	60 %	3
13	11	0,5	63 %	58 %	50 %	0,5
14	6	10	63 %	absentă	60 %	4
15	7	1	100 %	absentă	100 %	izoelectric
16	3,5	6	89 %	40 %	67 %	2
17*	12	1	100 %	absentă	100 %	izoelectric
18	3	11	60 %	absentă	73 %	3
19	2	3	33 %	54 %	75 %	1,5
20	8	5	!	absentă	!	7
21	3	0,5	echivoc	-	-	izoelectric
22	8	4	30 %	absentă	50 %	2

Supradenivelarea maximă de segmentului ST la 60 de minute postACTP, pentru IMA anterioare a permis încadrarea pacienților în grupele de risc mic – 2 cazuri (un caz cu arteră patentă), risc mediu – 3 cazuri (un caz cu arteră patentă), risc mare – 2 cazuri, iar pentru IMA inferioare ca grupe de risc mic – 2 cazuri (un caz cu arteră patentă), şi risc mediu – 3 cazuri (un caz cu arteră patentă).

Caracteristicile electrocardiografice evolutive, analizate la 8 pacienti pentru care ACPT primară a fost practicată tardiv (6-12 ore) au evidențiat:

- menținerea constantă a supradenivelării de segment ST şi aspect subacut la 9 zile pentru un caz, încadrat ca *no-reflow* ireversibil (necroza fiind deja constituită);

- reducerea supradenivelării de segment ST pentru celelalte 7 cazuri, astfel:

- rezoluția completă a sumST pentru supradenivelare a fost întâlnită la 2 pacienți (doar unul cu arteră patenta);

- rezoluția parțiala a sumST pentru supradenivelare a fost prezentă la 5 pacienți;

- rezoluția slST completă la 2 pacienți, parțială la 5 pacienți (în corespondență cu

sumST);

Supradenivelarea maximă de segment ST la 60 de minute postACTP, pentru IMA anterioare, a permis încadrarea pacienților în grupa de risc mediu – 2 cazuri (1 caz cu arteră patentă), iar pentru IMA inferioare ca grupe de risc mic – 4 cazuri (1 caz cu arteră patentă), şi risc mare – 1 caz.

DISCUȚII

Evaluarea *in vivo* a modificărilor morfologice consecutive stresului oxidativ, în corespondență cu fenomenul de reperfuzie miocardică, este extrem de dificil de realizat. Din acest motiv, am analizat posibilitatea de a utiliza o serie de metode de tip paraclinic, care pot furniza un set de dovezi funcționale – numite dovezi "surogat" - asupra fenomenului de reperfuzie eficientă, sau a leziunilor de reperfuzie.

Fluxul TIMI şi MBG (12), deşi metode subiective, sunt curent utilizate pentru definirea reperfuziei eficiente. Definiția angiografică a reperfuziei este reprezentată de asocierea TIMI 3 cu MBG 2-3; fluxul TIMI 3 este necesar, dar nu garantează reperfuzia optimă. TIMI 0-3 şi MBG 0-1 definesc fenomenul de *no-reflow*, TIMI 0-2 sugerează *no-reflow*, care însă poate fi prezent şi la TIMI 3, MBG 0-1 fiind elementul sugestiv pentru această complicație (observat în 50% din cazurile cu TIMI 3). Studiile axate pe investigarea fenomenului de reperfuzie miocardică raporteaza un prognostic foarte bun pentru MBG 2-3 şi rezoluție de segment ST > 70%, rezervat pentru MBG 0-1 şi rezoluție de segment ST < 70%, şi intermediar în rest; asocierea TIMI 3 cu MBG 0-1 aduce o mortalitate de 7 ori mai mare decât cu MBG 2-3 (6, 11, 15, 16, 17, 18). Leziunea de *no-reflow*, complicație a tratamentului de reperfuzie miocardică, este un termen utilizat în literatură pentru a descrie lipsa fluxului eficient în artera coronară responsabilă de infarct după deschiderea acesteia, fiind definit angiografic ca flux TIMI 0-3 cu MBG 0-1. În patogeneza sa multifactorială sunt implicate stresul oxidativ, prin leziunile de ischemie şi reperfuzie, emboliile distale, predispoziția individuală. Acest fenomen poate fi reversibil spontan sau terapeutic, sau susținut şi ireversibil, probabil funcție de reversibilitatea sau ireversibilitatea modificărilor microcirculației (11).

În lotul studiat, s-a practicat ACPT primară cu implantare de stent, şi s-a obținut ca rezultat final flux TIMI 3 cu *blush* miocardic şi fără *no-reflow* (MBG 2-3) în 21 cazuri (95,45%), din care 18 cazuri fără incidente intervenționale, pe care le-am apreciat ca reperfuzie eficientă (81,81%). Celelalte 4 cazuri (18,19%) au evoluat cu complicații ale tratamentului de reperfuzie, constând în fenomen de *no-reflow*. Aceste cazuri au fost definite, ca urmare a posibilităților de identificare angiografică a cauzelor de *no-reflow*, după cum urmează: 2 cazuri au prezentat embolii distale în LAD apical; un alt caz a evoluat cu obținerea unui flux inițial TIMI 1 fără *blush* (*no-reflow*) şi cu flux TIMI 3 şi cu *blush* după administrare intracoronariană de adenozină, nitroglicerină şi ser fiziologic cald - fenomen de *no-reflow* reversibil terapeutic. Un ultim caz a prezentat flux distal TIMI 1 fără *blush* în ciuda manevrelor folosite – fenomen de *no-reflow* ireversibil.

Interpretând aceste rezultate inclusiv prin rolul potențial al stresului oxidativ în leziunea de reperfuzie miocardică, putem considera că situațiile cu fenomen de *no-reflow*, reversibil şi ireversibil, au asociat un stres oxidativ important.

Analiza modificărilor electrocardiografice în dinamică constituie, prin informații-

le puternic obiective oferite, un instrument simplu dar, concomitent, extrem de adecvat pentru aprecierea eficacității reperfuziei şi implicit a prognosticului (15).

Rezoluția supradenivelării de segment ST la 60 de minute de la ACPT, măsurată la 20 de msec de punctul J, se corelează cu salvarea de miocard, permite stratificarea pacienților pe grupe de risc (mic, moderat sau intermediar, şi mare), cel mai facil pentru maxST, şi integrează perfect perfuzia miocardică şi tisulară. Acuratețea predictivă maximă este oferită de maxST, apoi de slST, şi cea minimă – de Sum ST. Astfel, dacă se interpretează SumST şi slST cu rezoluție completă şi maxST cu risc mic, există o probabilitate de > 90% ca artera responsabilă de infarct să fie patentă şi asociată cu perfuzie tisulară, iar pentru rezoluție absentă (SumST şi slST) şi maxST la risc mare, 50% au încă arteră patentă, dar fără perfuzie tisulară (11, 13, 14, 19, 20).

Rezoluția subdenivelărilor de segment ST (a modificărilor ECG reciproce, indirecte) aduce informații prognostice independente ce sunt incrementale cu cele reprezentate de supradenivelarea de segment ST (15).

Pe lotul studiat, am realizat o comparație a modificărilor electrocardiografice evolutive între pacienții pentru care ACPT primară a fost practicată precoce şi, respectiv, tardiv. În baza datelor furnizate prin evaluarea diferențelor de supradenivelare a segmentului ST, respectiv subdenivelare, putem aprecia că reperfuzia intervențională poate fi tradusă prin informații electrocardiografice. Aceste informații susțin eficacitatea ACPT primare pentru salvarea de miocard şi stratificarea riscului. Rezultatele favorabile sunt dependente de timpul de prezentare, şi independente de patența arterei afectate. Consecutiv, putem aprecia că modificările electrocardiografice evolutive pot fi considerate ca dovezi indirecte pentru leziunile produse prin stres oxidativ indus de reperfuzia miocardică, în condițiile în care intensitatea şi severitatea lor este dependentă şi de factorul timp.

CONCLUZII

Evaluarea prin dovezi alternative a reperfuziei miocardice oferă o serie de informații asupra modului de restabilire a integrității funcționale a miocardului, fără însă a permite o analiză a substratului biochimic şi morfologic al evoluției leziunilor, sub raportul intervenției stresului oxidativ. Studiul aprofundat al dinamicii modificărilor induse de stresul oxidativ, la nivel structural, impune, în condițiile particularității miocardului, un model experimental.

BINAURAL COCHLEAR IMPLANT – GOOD CHOICE IN THE TREATMENT OF DEEP SENSORINURAL HEARING LOSS (Abstract). Nowadays, cochelar implant is the only choice of treatment in deep bilateral deafness. **Aim:** To evaluate the benefits of binaural implantation of a single receiver-stimulator device by using audiometric tests at 3 and 6 months intervals. **Material and methods:** The study included 3 patients with bilateral sensorineural deafness of cochlear origin. Following implantation they were assessed by pure tone audiometry (PTA), speech audiometry (SA), and sound localization tests (LT). **Results:** PTA showed a significant decrease in hearing thresholds level during the 6-month interval following implantation. As to the degree of speech discrimination in both quiet and noisy environment, SA showed evident progress at 6 months compared to the results at 3 month. The location tests revealed improved sound localization in both ears at 6 months compared to the results at 3 months. **Conclusions:** Compared to unilateral implant, the binaural cochlear implant has the advantage of stereophonic hearing, facilitating the communication through a better understanding of speech in both quiet and noisy environment, and improving the quality of life by the location of sounds similar to natural hearing. **Key words:** BINAURAL COCHLEAR IMPLANT, SENSORINEURAL HEARING LOSS, AUDIOMETRIC TESTS

Implantul cochlear reprezintă metoda de tratament a surdităţii profunde bilaterale de câteva decenii. Conceptul implantării bilaterale a apărut odată cu rezultatele studiilor comparative efectuate la pacienţii cu auz normal sau cu proteze auditive convenţionale versus implant unilateral (monoaural), când au fost evidenţiate dezavantajele audiţiei monoaurale în viaţa de zi cu zi (1).

Totodată, mai multe colective de cercetare au dovedit şi au descris fenomenele de maturare neurologică şi de plasticitate a sistemului neural auditiv, fenomene posibile numai sub stimulare sonoră caracteristică (2, 3, 4). Astfel a apărut conceptul implantării bilaterale cu efectul său tehnologic, dezvoltarea unui sistem de implant cohlear binaural.

Implantarea bilaterală este posibilă, însă puţin probabilă în condiţiile din România datorită costului ridicat. Implantarea binaurală, adică folosirea unui singur dispozitiv pentru ambele urechi reprezintă o soluţie posibilă în cazul pacienţilor adulţi cu surditate bilaterală neuro-senzorială profundă, cu costuri mai mici. Singurul produs de

acest tip de pe piaţă este Implantul Cochlear Binaural Digisonic SP.

Implantarea cochleară binaurală, reprezintă o premieră în România, fiind realizată în Clinica ORL din Spitalul Clinic de Recuperare Iaşi, motiv pentru care prezentăm avantajele acestui tip de implant faţă de implantarea cochleară monoaurală.

CONSIDERAŢII ASUPRA IMPLANTULUI BINAURAL

1. Audiţia binaurală normală

La subiecţii cu auz binaural normal, spre deosebire de auzul monoaural, există un efect de creştere a senzaţiei de tărie sonoră cu 3 dB la nivelul pragului şi cu 10 dB la peste 30 dB, creştere esenţială pentru localizarea sursei sunetelor în spaţiu, pentru supresia ecourilor şi pentru auzul în mediul cu zgomot. Avantajele audiţiei binaurale se transformă în impedimente când este necesară testarea fiecării urechi în parte: fenomenul de transcraniere (capacitatea sunetului prezentat urechii testate de a se propaga prin craniu până la urechea opusă), poate conduce la erori audiometrice, în special în audiometria subiectivă. Datorita dezvoltării metodelor de mascare a urechii contralaterale celei testate, acest impediment a fost minimizat.

2. Audiţia binaurală prin implantul cochlear

Implantarea binaurală reprezintă o soluţie posibilă în cazul pacienţilor adulţi cu surditate bilaterală neuro-senzorială profundă, cu costuri mai mici. Implantarea cochleară binaurală prezintă faţă de implantarea cochleară unilaterală avantajele audiţiei stereofonice facilitând întelegerea şi localizarea sunetului mai bine şi mai natural (5, 6).

Considerăm acest tip de implant cochlear o alternativă terapeutică de interes major cu impact important în viaţa socială a pacientului reprezentând un factor de prognostic favorabil în evoluţia audiţiei pacientului. Singurul produs de acest tip de pe piaţă este implantul cochlear Digisonic SP Binaural (fig. 1).

Fig. 1. Implant cochlear *Digisonic SP Binaural*

Studiul îşi propune evaluarea avantajelor implantării binaurale şi monitorizarea, înregistrarea şi analizarea evoluţiei în timp a audiţiei tonale şi a perceperii vorbirii în mediul liniştit şi în zgomot, în corelaţie cu fenomenele de plasticitate cerebrală şi de adaptabilitate a pacienţilor la mediul sonor. În consecinţă, aceste avantaje conduc inerent la îmbunătătirea calităţii vieţii pacienţilor implantaţi.

MATERIAL ŞI METODĂ

Am inclus în studiu 3 pacienţi cu hipoacuzie neuro-senzorială bilaterală de origine cochleară şi cu inteligibilitate mai mică de 50% la 60 dB SPL cu proteză auditivă şi fără labiolectură.

Criteriile de excludere au fost următoarele: vârsta mai mică de 18 ani şi mai mare de 70 de ani, pacienţi pe care nu avem posibilitatea de a-i urmări în timp, pacienţi cu stare generală alterată, cu deficite neurologice anterioare, probleme ale scalpului,

alexie, infecţii ale urechii medii, durata surdităţii profunde a urechii celei mai afectate mai mare de 20 de ani şi diferenţa de durată a hipoacuziei profunde între cele două urechi mai mică de 20 de ani.

Pacienţii au fost implantaţi cu implantul cochlear tip Digisonic SP Binaural. Acesta este constituit din două părţi: partea externă şi partea implantabilă sau receptor-stimulatorul. Partea externă constă dintr-un singur procesor de sunet dotat cu microfoane ipsilaterale, la care se conectează microfonul auxiliar contralateral. Informaţia este transmisă părţii interne printr-o antenă sub formă de unde radio. Receptor stimulatorul este conectat la un port-electrod scurt pentru cochleea homolaterală şi un port-electrod lung pentru cochleea contralaterală (realizat special pentru a ajunge pe sub scalp de la o mastoidă la cealaltă) (fig. 2).

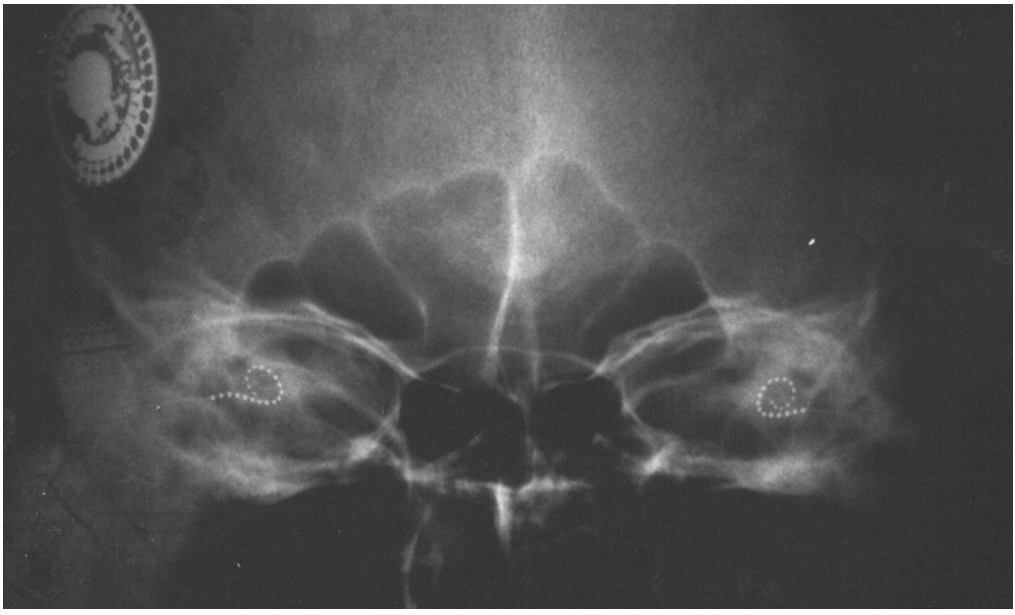

Fig. 2. Aspect imagistic al poziţionării implantului binaural (receptor-stimulator şi cei doi portelectrozi intracochleari).

Acest implant are câte 12 canale pe fiecare port-electrod. La fiecare port-electrod este conectat un electrod de masă. Procesorul este în totalitate digital şi permite flexibilitate în ajustarea parametrilor de stimulare prin intermediul softului de reglaj.

Receptor-stimulatorul unic este controlat printr-un procesor retroauricular care primeşte informaţii din ambele hemicâmpuri auditive graţie microfoanelor ipsilateral şi contralateral. Procesorul de sunet este capabil sa prelucreze 2 semnale stereo concomitent, procesarea stânga - dreapta putându-se realiza independent.

Decalajul temporal dintre cele două urechi este asemănătoare cu cel natural şi corespunde distanţei necesare sunetului de a ajunge la microfonul ipsilateral şi respectiv controlateral. Cel mai mare avantaj faţă de implantarea bilaterală îl reprezintă stimularea cu un singur procesor şi astfel se obţine o mai bună precizie temporală între

cele două urechi.

În decursul studiului s-au efectuat mai multe teste audiologice conform protocolului stabilit: pre-operator, la data activării, la 3 luni şi ultimele la 6 luni de la activare. Testele de evaluare au durat în medie o oră şi jumătate pe şedinţă şi au fost aplicate pentru testarea audiţiei monoaurale pe fiecare ureche, iar apoi pentru testarea audiţiei binaurale. Acestea s-au desfăşurat în incintă cu atenuare fonică, folosind echipament calibrat (audiometru Interacoustics, preamplificator, sistem de 5 boxe amplasate în semicerc la fiecare 45°, sistem de reglaj al implantului). Testele folosite sunt descrise mai jos.

Ca prim test s-a realizat audiometria tonală liminară pentru urechea dreaptă, urechea stângă şi ambele urechi. Se determină pragurile auditive la stimularea în câmp liber pe frecvenţele de 250, 500, 1000, 2000 şi 4000 Hz. Rezultatul ATL în câmp liber permite stabilirea performanţei auditive a tonurilor pure prin implantul cohlear.

Un al doilea test folosit a fost audiometria vocală. Prin prezentarea unor liste adaptate de câte 10 cuvinte bisilabice standardizate la intensităţile de 70 şi 80 dB SPL, s-a evaluat performanţa pacientului în recunoaşterea limbajului atât în mediul liniştit, cât şi în mediul cu zgomot. S-a înregistrat curba de inteligibilitate vocală, identificându-se pragul de inteligibilitate (intensitatea la care subiectul a recunoscut 50% dintre cuvintele prezentate) (9).

Deoarece este vorba despre pacienţi la care, prin implantul binaural, s-a restaurat audiţia stereofonică, după activarea implantului am urmărit evoluţia performanţelor pacienţilor privind identificarea localizării susei sonore. Testele au fost efectuate în cabina izolată fonic, utilizând sistemul de 5 boxe amplasate conform figurii 3. Distribuţia spaţială a boxelor are ca scop identificarea de către pacient a direcţiei de unde sunt emise sunetele. Boxele sunt calibrate, iar semnalul este emis prin intermediul unui amplificator de semnal etalonat, conectat la audiometru. Stimulul este un zgomot alb prezentat la intensitatea de 65dB SPL. Pentru fiecare pacient a fost folosit un algoritm de lucru care a cuprins câte 10 teste pentru fiecare boxă, emise aleatoriu, deci în total 50 de stimuli pentru care pacientul a trebuit să identifice direcţia din care a fost prezentat.

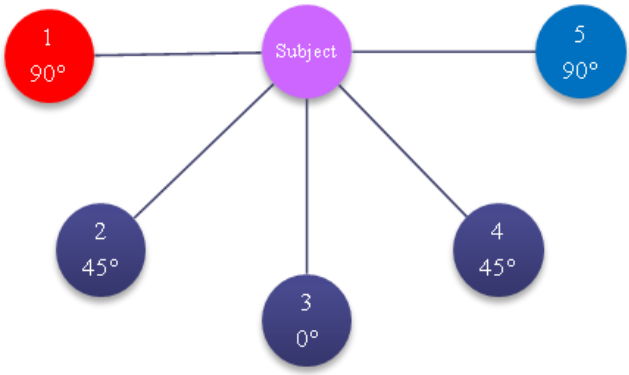

Fig. 3. Distribuţia spaţială a boxelor în câmp liber

REZULTATE ŞI DISCUŢII

În cazul ATL efectuate la cei 3 pacienţi incluşi în studiu se poate observa o scădere semnificativă a valorii pragurilor auditive înregistrate de la activare până la 6 luni după aceasta, deci o îmbunătăţire a percepţiei tonale atât pentru fiecare ureche în parte (dreapta-roşu, stânga – albastru), dar mai ales pentru auzul binaural (verde) (fig. 4).

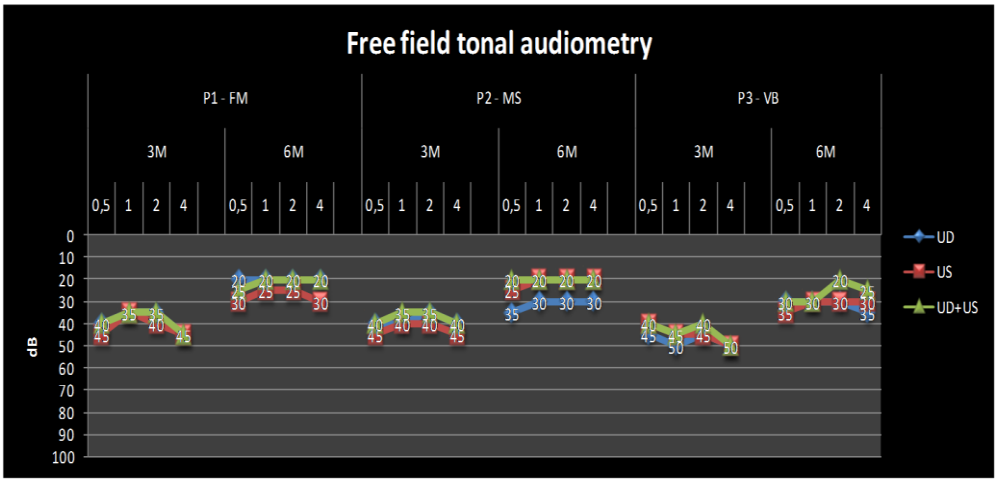

Fig. 4. Audiogramă tonală liminară

Putem observa că nivelul de audiţie în momentul testării ambelor urechi este pentru primele 2 cazuri testate (P_1 şi P_2) la nivelul maxim de audiţie pe care l-a înregistrat pacientul cu oricare ureche testată individual, iar în cazul pacinetului P_3 pragurile auditive pentru cele 2 urechi testate concomitent (la 6 luni) sunt chiar mai scăzute (pentru frecventele 2.000Hz şi 4.000Hz) decât pragurile înregistrate pe oricare ureche testată individual, deci auzul s-a îmbunătăţit considerabil de la sesiunea de reglaj şi control la 3 luni de la implantare şi apoi la 6 luni la toţi pacienţii.

În cazul discriminării vorbirii la 60 şi 70 dB SPL în linişte, rezultatele înregistrate la 6 luni de la activare comparativ cu cele înregistrate la 3 luni de la activare sunt similare pentru primul pacient (P_1). Putem observa o recunoaştere mai bună a cuvintelor la 60 dB SPL la testarea auzului binaural decât testarea pentru fiecare ureche în parte. În schimb pacientul P_2 a prezentat o îmbunătăţire semnificativă la 6 luni a recunoaşterii cuvintelor atât pentru fiecare ureche în parte, dar mai ales în testarea binaurală. De asemenea, gradul de recunoaştere a cuvintelor la testarea ambelor urechi concomitent a fost mai mare decat în cazul testării fiecărei urechi în parte. Acest tipar de evoluţie este asemănător cu majoritatea cazurilor implantate binaural pe care le-am analizat în comunicările din literatura de specialitate (10, 11). La ultimul pacient testat s-a înregistrat o îmbunătăţire a audiţiei pentru urechea dreapta de la 3 luni la 6 luni însă fară un progres evident pentru urechea stângă. Performanţa testării binaurale la 3 luni a fost la nivelul audiţiei înregistrate cu urechea dreaptă la acelaşi moment. La testarea ambelor urechi la 6 luni la 60 dBSPL

s-a înregistrat o ameliorare a gradului de recunoaştere a cuvintelor, dar nu până la nivelul atins de urechea dreaptă, iar pentru intesitatea de 70 dBSPL s-a înregistrat chiar o scădere a gradului de recunoaştere a cuvintelor, ajungâdu-se la nivelul audiţiei urechii stângi (fig. 5).

Putem observa că la testarea de la 6 luni după momentul activării, în cazul tuturor pacienţilor, se înregistrează apariţia fenomenului de recruitment prin scăderea gradului de recunoaştere a cuvintelor la intensitatea de 70 dB faţă de 60 dB. În cazul testării la 3 luni putem observa fenomenul de recruitment pentru pacientul P_1 pentru fiecare testare în parte iar pentru pacientul P_2, fenomenul a apărut doar în momentul testării separate a fiecărei urechi.

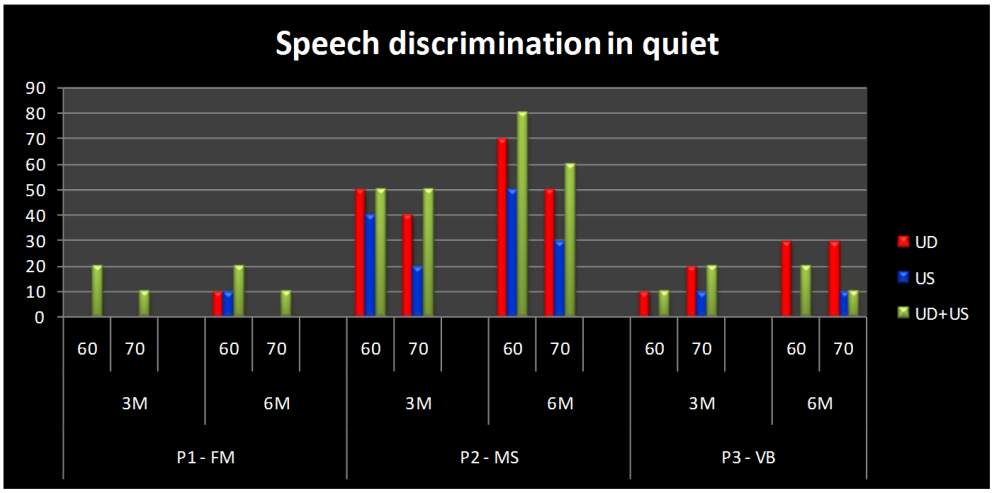

Fig. 5. Audiogramă vocală în linişte

Pentru audiograma vocală în mediul cu zgomot (zgomot alb cu intensitatea de 60 dB) pentru discriminarea vorbirii la 60 şi 70 dB SPL putem observa lipsa răspunsului şi la 3 luni şi la 6 luni din partea pacientului P_1. Pentru pacientul P_2 se poate observa o audiţie binaurală la fel de bună ca şi pentru cea mai bună ureche testată (urechea dreaptă) la 3 luni după activare şi o îmbunătăţire a gradului de recunoaştere la 6 luni, comparativ cu testarea la 3 luni, pe fiecare ureche individuală testată cât şi pentru ambele urechi testate concomitent. În schimb audiţia binaurală la 6 luni a înregistrat o îmbunătăţire a gradului de recunoaştere faţă de urechea cea mai bună testată (urechea dreaptă) atât pentru intesitatea de 60 dBSPL cât şi pentru 70 dBSPL. În cazul acestui pacient am observat apariţia fenomenului de recruitment la testarea de la 3 luni după activarea implantului cochlear binaural pentru urechea dreaptă.

Pentru pacientul P_3 s-a înregistrat o îmbunătăţire a gradului de recunoaştere la 6 luni comparativ cu testarea la 3 luni pentru audiţia cu ambele urechi concomitent şi o staţionare pentru urechea stângă pentru ambele intesităţi testate. Pentru urechea dreaptă nu s-a obţinut răspuns la 60 dBSPL pentru ambele momente de testare însă s-a înregistrat o îmbunătăţire la 6 luni pentru intesitatea de 70dB SPL, gradul de recunoaştere fiind chiar mai mare decât în cazul audiţiei binaurale (fig. 6).

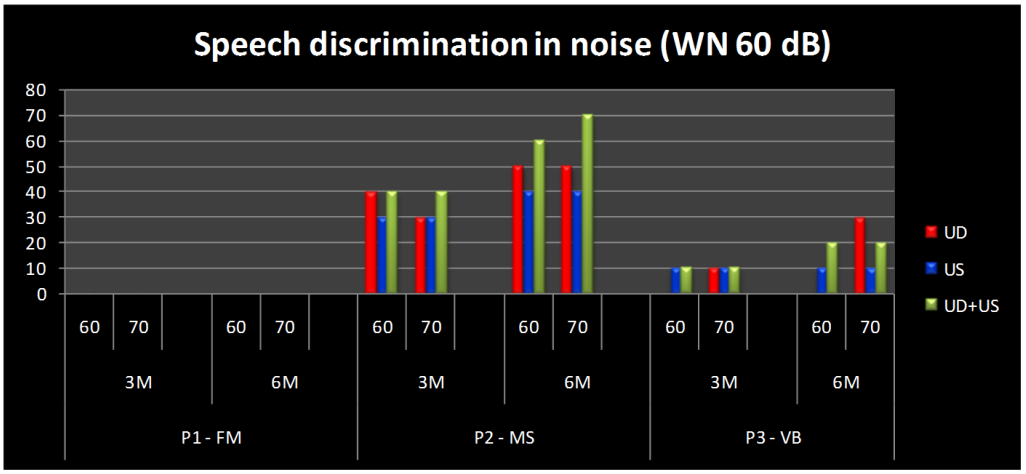

Fig. 6. Audiogramă vocală în mediu cu zgomot

În cazul testelor de localizare cu 5 boxe şi zgomot alb de 65 dBSPL s-a observat o bună localizare a originii sunetului spre dreapta în momentul stimulării urechii drepte şi o bună localizare a originii sunetului spre stânga în momentul stimulării urechii stângi (fig. 7).

Pentru stimularea binaurală localizarea apare cu precizie mai mică decât în cazul urechilor stimulate individual pe partea corespunzătoare fiecăreia, însă cu rezultate bune pentru localizarea laterală de fiecare parte. Pentru sunetele prezentate din boxa frontală localizarea a fost slabă, dar mai precisă decât în cazul stimulării individuale pe fiecare ureche. S-a observat o îmbunătăţire în ceea ce priveşte localizarea sursei zgomotului în audiţia binaurală de la testarea iniţială după 3 luni de la activare şi testarea la 6 luni de la activare în cazul tuturor pacienţilor testaţi. Imbunătăţirile s-au înregistrat atât pentru localizarea boxelor laterale dar mai ales pentru localizarea boxelor din regiunea centrală.

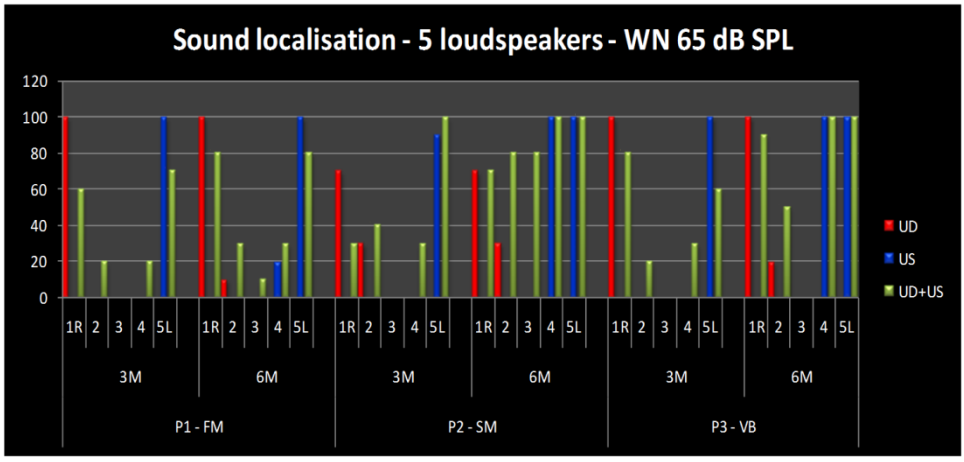

Fig. 7. Localizarea sursei sunetului

Din datele înregistrate în cursul studiului la audiograma tonală liminară am observat că auditia binaurală permite detecţia unor praguri mai scăzute sau cel puţin egale cu pragurile obţinute în cazul audiţiei monoaurale şi am notat o evoluţie în timp spre scăderea pragurilor auditive de la 3 luni la 6 luni. De asemenea am notat un progres la testarea de la 6 luni faţă de testarea de la 3 luni după activare în ceea ce priveşte gradul de discriminare a vorbirii atât în linişte cât şi în mediul cu zgomot în cazul testării audiţiei binaurale pentru pacienţii P_2 şi P_3.

Pentru testele de localizare s-a înregistrat o îmbunătăţire a localizării originii zgomotului (atât pentru boxele laterale dar mai ales pentru boxele centrale) în audiţia binaurală la testarea de la 6 luni faţă de testarea de la 3 luni după activare în cazul pacienţilor testaţi. Acest fapt indică o evoluţie în timp spre audiţia cât mai apropiată de cea naturală stereofonică şi se poate explica prin fenomenele de plasticitate neuronală şi de adaptabilitate a fiinţei umane la o nouă formă de percepere a mediului sonor.

Implantul cohlear binaural fiind constituit dintr-un singur procesor de sunet, un singur receptor-stimulator şi de 2 port-electrozi, reprezintă o alternativă mai puţin costisitoare, cu o mai bună precizie temporală între cele 2 urechi şi cu un timp chirurgical mai scurt decât implantarea bilaterală. În schimb, în cazul în care s-ar produce o defecţiune a receptor-stimulatorului, pacientul şi-ar putea pierde complet capacitatea de a auzi.

Implantarea cochleară binaurală prezintă avantajele audiţiei stereofonice facilitând întelegerea şi localizarea sunetului mai bine şi mai natural.

CONCLUZII

În tratamentul hipoacuziilor neuro-senzoriale profunde şi unele hipoacuzii severe, metodele de protezare convenţională nu pot fi utilizate. În aceste cazuri soluţia terapeutică o reprezintă implantul cochlear. Implantarea binaurală prezintă faţă de implantarea unilaterală avantajele audiţiei stereofonice, facilitând comunicarea printr-o mai bună înţelegere a vorbirii în linişte şi în mediul cu zgomot şi îmbunătăţind calitatea vieţii oferind posibilitatea localizării surselor sonore asemănător auzului natural.

RESOLUTION OF INFLAMMATION - PHARMACOLOGICAL ASPECTS (Abstract): Inflammation is a fundamental biologic process evolutionally preserved by a germ line code. The interplay of the epigenetic with the environment directs the code to temporally distinct inflammatory responses, which can be acute or chronic. The aim of this study is to present new aspects regarding the resolution of inflammation**.** Acute inflammation normally resolves by mechanisms still somewhat elusive. Current evidence suggests that an active coordinated program initiated the first few hours after the inflammatory response begins and its failure lead to chronic inflammation. This process is essential for appropriate host responses, tissue protection and the return to homeostasis. Prostaglandins and leukotrienes are lipid mediators that play important roles in host defense and acute inflammation. Granulocytes promote the switch of arachidonic acid–derived prostaglandins and leukotrienes to lipoxins, active anti-inflammatory and pro-resolution mediators. The apoptosis of the neutrophils coincides with the biosynthesis of resolvins and protectins from omega-3 polyunsaturated fatty acids and releases anti-inflammatory and reparative cytokines. This information could lead to new treatments for inflammatory diseases**. Key words:** INFLAMMATION, RESOLUTION, MEDIATOR, ARACHIDONIC ACID

Termenul de ***inflamație*** defineşte un proces protectiv complex de răspuns tisular inițiat secundar acțiunii unor factori mecanici, chimici, fizici, bacterieni, ce au drept rezultat lezarea sau chiar apoptoza celulară (1). Lezarea celulară determină eliberarea de mediatori de tip inflamator, în categoria cărora sunt incluse citokinele, TNF-alfa, interleukinele, leucocitele, monocitele sau macrofagele (2). Actualmente se consideră că citokinele intervin în stimularea chemokinelor, imunoglobulinelor, altor citokine pro-inflamatorii şi în stimularea expresiei moleculelor de adeziune (3). **Procesul de rezoluție a inflamației** este reprezentat de mecanismele endogene antiinflamatorii care protejează organismul împotriva unor leziuni inflamatorii exagerate şi stimulează procesele de reconstrucție tisulară postinflamatorie (4, 5).

1. INFLAMAȚIA ACUTĂ

Inflamația acută, caracterizată prin recrutarea leucocitelor din circulație, se defineşte clasic printr-un mecanism de inițiere a unui trafic de PMN (polimorfonucleare neutro-

file), urmat de monocite, care se diferențiază ulterior pe plan local în macrofage. Invariabil, acest răspuns este declanşat de mastocitele tisulare şi macrofagele rezidente, a căror degranulare şi activare eliberează secvențial mediatori inflamatori, inclusiv amine bioactive (histamina şi 5-HT), citokine, chemokine precum şi mediatori lipidici care recrutează şi activează celulele inflamatorii, determinând formarea edemului (6).

Răspunsul inflamator se caracterizează prin activarea coordonată a diferitelor căi de semnalizare care reglementează expresia mediatorilor pro- şi anti-inflamatorii din celulele rezidente tisulare şi leucocitele recrutate. În prezent, argumentele privind semnalizarea inflamației derivă din studiile asupra membrilor familiei receptorilor interleukinei (IL) precum IL-1R, TNF şi TLR, care aparțin familiei IL-1R (7). IL-1 şi TNF alfa reprezintă citokine arhetipale pro-inflamatorii care sunt rapid eliberate la nivelul leziunii sau infecției tisulare (8) Căile de semnalizare proinflamatorie induc expresia paralelă de mediatori antiinflamatori (de exemplu, IL-10 (tab. I).

TABELUL I

Citokinele şi rolul lor în inflamație (5)

Citokine	Celula sursă	Celula țintă	Acțiune
Citokine proinflamatorii			
IL-1	Macrofagele Celulele dendritice	Limfocitele Celulele endoteliale Celulele din SNC Celulele hepatice	Stimularea răspunsului Activare celulară Febră, stare de rău Sinteza şi eliberarea proteinelor de fază acută
IL-6	Macrofagele Celulele dendritice Endoteliu Celule Th2	Celulele hepatice Celula B	Sinteza şi eliberarea proteinelor de fază acută Proliferare
TNF-alfa	Macrofagele Celulele dendritice Celule Th1	Celulele endoteliale Neutrofilelor Hipotalamusului Celulelor hepatice	Activarea endoteliului vascular prin creşterea permeabilității si stimularea moleculelor de adeziune Activare celulară Febră Sinteza şi eliberarea proteinelor de fază acută
Citokine antiinflamatorii			
IL-10	Macrofagelor Celulelor Th2	Macrofagelor Celulelor dendritice	Inhibă producerea de IL-12 Inhibă sinteza de citokine proinflamatorii
IL-12	Macrofage Celule dendritice	CD4 + celule T helper Celule NK	Diferențierea Th1 Sinteza IFN-gamma
Citokine implicate în apariția răspunsului imun			
IL-2	Celule T	Celule T Celule NK Celule B	Proliferare Activare şi proliferare proliferare
IL-4	Celule Th2 Celule mastocitare	Celule T Celule B Macrofage	Dezvoltarea celulelor Th2 Inhibă activarea IFN-gamma
IFN-gamma	Celule Th1 Celule T citotoxice Celule NK	Celule T Celule B Macrofage	Dezvoltarea celulelor Th2 Activare

Dispariția stimulului determinant al procesului inflamator acut inițiază inhibarea sintezei de mediatori proinflamatori (eicosanoizi, chemokine, citokine, molecule de adeziune, etc), stimularea catabolismului lor şi blocarea căilor de semnalizare proinflamatorie (tab. I). Astfel se opresc procesele de recrutarea de leucocite şi formare a edemului, etape care, asociate cu eliberarea factorilor care previn traficul PMN-urilor şi eozinofilelor, reprezintă "începutul sfârşitului" şi anume ***rezoluția răspunsului acut inflamator*** şi reîntoarcerea la homeostazie (9)

Eşecul rezoluției răspunsului acut inflamator determină apariția inflamației cronice.

2. REZOLUȚIA INFLAMAȚIEI

O serie de semnale endogene antiinflamatorii, de tipul corticosteronului, moderează gravitatea şi limitează durata fazei de debut. Pe parcursul progresiei procesului inflamator, acțiunea anumitor "semnale stop" pe o serie de "puncte de control" previne traficul leucocitar tisular suplimentar. Semnalele stop includ ***lipoxine, resolvine şi prostaglandine (PG) din seria D*** care deschid calea pentru migrarea şi diferențierea monocitelor în macrofage fagocitante cu rol în eliminarea celulelor moarte, şi care părăsesc ulterior *situs*-ul inflamator (10).

Lipoxinele

Literatura de specialitate (9) descrie trei căi majore de generare a lipoxinelor (LXA4, LXB4, epi-LXA4 şi epi-LXB4) pornind de la acidul arahidonic: calea 5 lipooxigenazei (eng. *5*-lipoxygenase - 5LO), calea 15 lipooxigenazei (15LO) şi calea epi-lipoxinelor declanşate de acidul acetil salicilic (ASA), care implică ciclooxigenaza 2 (eng. *cyclooxygenase-2* - COX2) şi 5-LO.

Expunerea la citokine induce expresia COX-2 în celulele endoteliale vasculare. Această moleculă este acetilată de ASA, iar activarea celulară prin receptorii membranari generează 15R-HETE, transformat de 5-lipooxigenaza (5-LO) neutrofilelor în 15-epi-lipoxine (fig. 1).

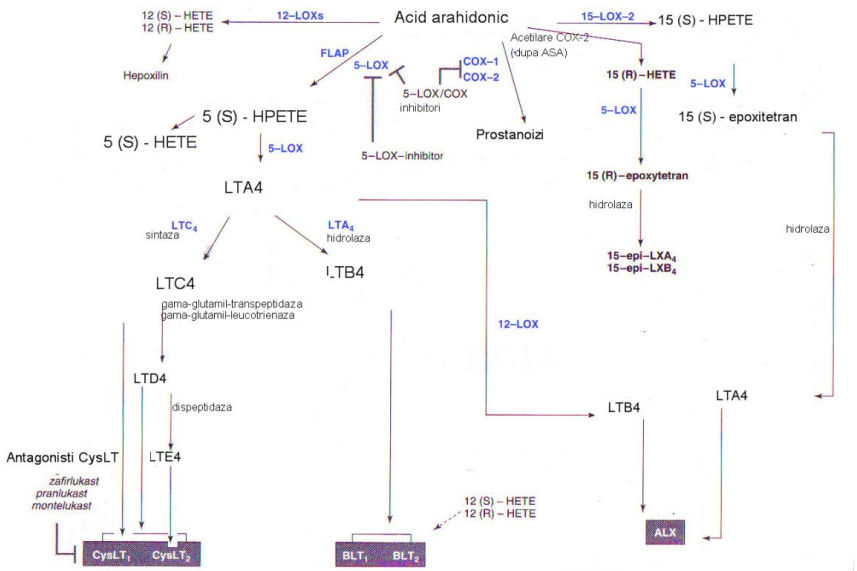

Fig. 1. Metabolismul acidului arahidonic (adaptat după Goodman **&** Gilman's)

ASA acetilează COX2 şi declanşează activitatea catalitică pentru transformarea acidului arahidonic în 15R-HETE (eng. *15-Hydroxyeicosatetraenoic acid* (**15-HETE**) *receptors*). 15R-HETE este eliberat din celulele endoteliale şi epiteliale şi transformat de 5-LO în lipoxine declanşate de ASA (ATL).

Lipoxinele, în special LXA4, constituie semnale puternice de contrareglare a unor mediatori endogeni proinflamatori, de tipul lipidelor (leucotriene, PAF) şi citokinelor (TNFα, IL-6), ce determină inhibiția inflamației dependentă de leucocite (11).

Rezolvinele şi protectinele

Studii recente au identificat noi mediatori generați din acizii graşi polinesaturați (eng. *polyunsaturated fatty acids* - **PUFA**) din dietă, cum ar fi **acidul eicosapentenoic (**eng. *eicosapentaenoic acid* - **EPA) şi acidul docosahexenoic (**eng. *docosahexaenoic acid* - **DHA)** (12). Aceşti compuşi, numiți rezolvine, docosatriene şi neuroprotectine, îndeplinesc rol antiinflamator şi au acțiuni prorezoluție, constituindu-se în inhibitori puternici ai migrării endoteliale a PMN-urilor şi ai expresiei citokinelor (13).

Compuşii derivați din EPA, care prezintă acțiuni biologice importante, sunt desemnați ca seria E, având în vedere precursorul lor EPA, notate şi ca **resolvine** din seria E (resolvine E1 sau RvE1), iar cele cu precursor DHA sunt rezolvine din seria D (resolvine D1 sau RvD1). Atât clasa de rezolvine D cât şi E sunt modulatori ai infiltrării PMN-urilor. Derivații bioactivi ai DHA, conjugați cu structuri de tip triene, sunt docosatrienele (eng. *docosatriene* – **DTS**), imunomodulatoarele şi neuroprotectoarele denumite **protectine/neuroprotectine.**

Având în vedere că aceşti mediatori sunt generați endogen în timpul unor intervale definite în timpul răspunsului inflamator, se poate concluziona că nu determină doar blocarea sau inhibarea inflamației, ci intervin în activarea rezoluției în exudatul inflamator, promovând întoarcerea la homeostazie.

Faza terminală a rezoluției

Faza terminală a rezoluției, constitutivă (mediată de PMN şi eozinofile) sau adaptativă (mediată de limfocitele), prezintă o serie de etape comune. La finalizarea inflamației acute, PMN-urile şi eozinofilele sunt eliminate într-o manieră controlată şi eficientă, proces denumit *moarte celulară programată sau apoptoză.*

Etapele parcurse de leucocitele inflamatorii includ recircularea sistemică sau moartea locală a PMN, eozinofilelor sau limfocitelor infiltrate, urmată de fagocitarea lor de monocitele derivate din macrofage. Odată fagocitoza finalizată, macrofagele pot părăsi țesutul inflamat pe cale limfatică, deşi o mică parte a acestora sunt distruse apoptotic la locul de fagocitoză (14).

Celulele stromale de tipul fibroblaştilor, contribuie la rezoluția inflamației prin retragerea semnalelor de supraviețuire şi normalizarea gradientului chemokinelor, permițând leucocitelor infiltrante să urmeze căile apoptotice sau să părăsească țesutul prin drenare limfatică (15, 16). Această secvență conduce la *rezoluție tisulară completă* şi, important, la restaurarea țesutului inflamat la starea de echilibru fiziologic.

3. IMPLICAȚII FARMACOTERAPEUTICE ALE FENOMENULUI DE REZOLUȚIE A INFLAMAȚIEI

Rezoluția inflamației acute cuprinde mecanisme endogene anti-inflamatoare care limitează prejudiciul excesiv tisular şi pro-

movează refacerea structurii şi funcţiei ţesutului. Rezoluţia este un proces activ, iar eşecul său conduce la iniţierea proceselor caracteristice inflamaţiei cronice. Descoperirea naturii active a procesului de rezoluţie a deschis modalităţi pentru o abordare nouă în terapia antiinflamatorie - iniţierea sau accelerarea rezoluţiei inflamaţiei acute, ca mecanism pentru tratamentul inflamaţiei cronice.

1. În timpul rezoluţiei inflamaţiei, neutrofilele activate trebuie eliminate în siguranţă prin apoptoză. Datorită implicării s**uperoxid-dismutaza (**eng. *superoxide dismutases* - **SOD)** în reglarea apoptozei neutrofilelor, s-a sugerat că ar putea fi utilizată ca agent terapeutic în tulburările inflamatorii. Tratamentul cu analogi SOD reduce producţia de citokine proinflamatorii, desfiinţează expresia moleculelor de adeziune celulară la suprafaţa celulelor endoteliale şi inhibă infiltrarea neutrofilelor. Analogii SOD sunt cunoscuţi în inhibarea producţiei de citokine, inclusiv a factorului de necroză tumorală alfa (TNF-a), interleukina (IL)-1b, şi IL-6, după cum se arată în modelele inflamatorii studiate (17).

Neutrofilele activate secretă specii reactive de oxigen (eng. *reactive oxygen species* - **ROS**) şi constituenţi primari granulari, iar acestea conduc uneori la prejudiciu tisular. Raportul oxidanţi/antioxidanţi este parţial implicat în patogenia inflamaţiei. În condiţii de stres oxidativ **superoxid dismutaza** acţionează ca un sistem de apărare celulară endogen, degradând superoxidul (O2) în oxigen şi peroxid de hidrogen, ca sunt ulterior detoxifiate de glutation peroxidază sau catalază. De aici derivă potenţialul terapeutic al SOD în tratamentul bolilor inflamatorii (18, 19).

2. Un alt pas important în procesul de rezoluţie îl reprezintă producerea de **mediatori lipidici pro-rezoluţie**, molecule mici care derivă din acizii graşi esenţiali omega-6 (acid arahidonic) şi omega-3 (acidul eicosapentaenoic şi acidul docosahexanoic), acizi graşi polinesaturaţi în alimentaţie. Primul agent dovedit a modula rezoluţia a fost **lipoxina**, o moleculă derivată din acidul arahidonic, apărută ca membru prototipic al lipidelor endogene/mediatori chimici activate în faza de rezoluţie a unui răspuns inflamator, şi care acţionează ca "semnalele stop" în inflamaţie (20, 21).

Alte două noi familii de mediatori lipidici recent identificate sunt **resolvinele** (produşi de interacţiune în faza de rezoluţie) şi **protectinele,** derivaţi din acizi graşi polinesaturaţi omega-3. Între aceşti controlori endogeni, căile lipooxigenazei şi ciclooxigenazei au funcţii protective şi proinflamatorii, cu rol precis pentru fiecare enzimă, exercitat în funcţie de stimuli, faza răspunsului inflamator acut (când aceste enzime sunt exprimate) şi momentul rezoluţiei (22).

În concluzie, rezolvinele şi DTS sunt familii noi de mediatori lipidici, cu structură unică şi proprietăţi antinflamatorii complementare ce pot înlătura inflamaţia şi prejudiciul mediat de PMN în multe boli umane (23, 24).

3. Cercetările recente au evidenţiat că **glucocorticoizii,** a căror proprietăţi antiinflamatorii erau bine cunoscute, influenţează mecanismele implicate în determinismul rezoluţiei, mai precis apoptoza (moartea celulară programată) la majoritatea leucocitelor şi stimulează *clearance*-ul celulelor apoptotice de către fagocite. *Clearance*-ul leucocitelor apoptotice poate fi un mecanism suplimentar prin care glucocorticoizii exercită acţiuni antiinflamatorii (25).

CONCLUZII

Rezoluţia inflamaţiei poate fi considera-

tă parte integrantă a procesului inflamator acut. Procesele implicate în rezoluție sunt influențate de interacțiunile dintre mediatorii chimici, de apoptoza leucocitelor sau de fagocitoză (26, 27). Factorii exprimați în timpul rezoluției ar putea fi folosiți direcționarea inflamației în curs de desfăşurare spre o cale prorezolutivă. O astfel de abordare ar însemna molecule în curs de dezvoltare care exercită efecte multiple la diferite faze ale răspunsului inflamator-limitarea traficului de leucocite, accelerarea *clearance*-ului celular, şi ajută la restabilirea țesutului stromal inflamat la starea sa anterioară (28, 29).

Medicamentele anti-inflamatorii curente blochează sau antagonizează căi ale mediatorilor pro-inflamatori implicate în inițierea unui răspuns inflamator acut (30). Prin urmare, cea mai mare parte a AINS blochează căile biochimice şi/sau mecanismele cheie de semnalizare pro-inflamatorie. Acest lucru ar putea fi definit ca **terapie de depleție (31).**

Abordarea terapeutică bazată pe *fenomenul rezoluției* ar necesita o schimbare a accentului de pe **terapia de depleție** pe **terapia de substituție**. Medicamentele rezoluției, precum cele revizuite în acest material, ar acționa antagonic, servind ca activatori, de exemplu, agonişti ai receptorilor, care activează mecanisme de protecție ce conduc la rezoluția inflamației acute şi reîntoarcerea la homeostazie.

THE ANCIENT INDIAN FLAP: A TECHNIQUE STILL UP TO DATE (Abstract): **Aim**: To reevaluate an old surgical technique that is still used and even up to date. **Material and methods:** A series of 24 patients was reviewed: 10 women and 14 men aged 55 to 84 years who underwent surgery between 2011 and 2017. All patients had various facial lesions removed from the nasal pyramid, nose and cheek region, nose and upper lip, and from the internal angle of the orbit. Most of the removed lesions were malignant- basal cell and squamous cell carcinomas, with only one benign lesion consisting of a hemangioma. For covering of the post-excisional defect, the Indian flap was used and mobilized into the defect by rotation, transposition or tunneling of an island flap. **Results:** Favorable results were achieved from a cosmetic and functional point of view, without any flap loss. Illustrative cases for each type of lesion and performed flap are presented and the postoperative outcomes are exemplified. **Conclusions**: The Indian flap remains the gold standard to cover defects in the nasal and neighboring regions. **Keywords**: INDIAN FLAP, BASAL CELL CARCINOMA, SPINOCELULAR CARCINOMA, PEDICLED FLAP.

The term flap has various connotations in anatomy and medicine. In plastic and reconstructive surgery, a flap is the tissue transferred from the place of origin (donor area) to another site (receiving area), to cover a post-traumatic or post-excisional defect. When a flap contains skin and subcutaneous cellular tissue it is called a cutaneous (skin) flap. The flaps may also contain other tissues (fascia, muscles and even bones) and are thus called composite flaps. Often, for the reconstructive surgery of the face, skin flaps are used. Flaps can be further classified into free flaps and pedicled flaps.

Free flaps are usually composite flaps that do not have a connection with the donor area. After transfer the blood supply is provided by the vessels of the receiving area that are anastomosed to the flap vessels by microsurgical techniques. The transfer of free flaps was possible thanks to the development of microsurgery technology and techniques and it represents an important breakthrough in plastic and reconstructive surgery (1, 2).

Pedicled flaps are vascularized from the region where they come from. They remain a priority indication for covering small and medium sized defects, especially on the face (3). The theoretical and technical principles governing the mobilization of pedicled skin flaps have originally been devel-

oped empirically. The use of frontal skin flaps for nasal reconstruction dates from ancient India. Around the year 700 BC, nasal amputation was a common punishment for a variety of crimes. The treatment of this infirmity was described in Sushruta Samhita (4). The technique today called "Indian flap" was brought to Europe in the fifteenth century and finally reached the United States in the 1830s. Subsequently, the name "Indian flap" was extended by some authors to other types of pedicled flaps on the face. The theoretical and technical principles of these types of flaps have been corrected, completed and well established over time, based on experimental and clinical studies (5, 6). Today it is known that for skin flaps, the vascularization from the donor area can be random and un-systematized (a random flap or joint flap). In order to have reliable viability, the length of this flap must be equal to the width. The blood supply of the donor area can also be provided by the subcutaneous vascular paths in the flap axis: the axial flap. The length of the axial flap may well exceed the width. The Indian flap falls into this last category (7).

The mobilization of the flaps, whether common or axial, is performed by various techniques (advancement, rotation, transposition, tunneling of island flaps). When the donor area is not adjacent to the receiving area, sutures inserted at the defect edges hold the pedicle of the flap as a bridge between the two areas. About 21 days (that can be prolonged in some situations) are needed for establishing the vascular connections in the new site. After this time, the vascularization (linking) with the donor area can be cut. The surgical technique is called flap autonomization and it involves cutting the pedicle and then performing the reconfiguration of the flap. For island flaps, autonomization is not necessary (8).

MATERIAL AND METHODS

Our study is a retrospective analysis of 24 patients with post-excisional defects of the face, who underwent surgery between 2011 and 2017, of which 10 (41.7%) females and 14 (58.3%) men, aged 55 to 84 years. The primary lesion was classified as basal cell carcinoma (BCC) in 19 (79.2%) cases (of which four were tumor recurrences), squamous cell carcinoma (SCC) in 4 (16.7%) patients and hemangioma in one (4.1%) patient (tab.I). The lesions were located as follows: seven (29.2%), on the nasal pyramid, eight (33.3%) on the nose and cheek regions, four (16.7%) on the nose and upper lip, and five (20.8%) at the internal angle of the orbit. For covering the surgical defect, the Indian flap (the axial paramedian frontal flap) was used. The mobilization of the flap was performed using the rotation technique in four (16.7%) cases, by flap transposition (the "classic flap") in 19 (79.2%) cases and in one (4.1%) case an insular flap was performed.

TABLE I

Distribution of the study patients

Sex				Tumor histology						Initial tumor localization

Type of Indian flap					
Rotated		Trans positioned		Insular flap	
No	%	No	%	No	%
4	16.7	19	79.2	1	4.17

RESULTS

The functional and esthetic outcomes were good in all patients with accurate restoration of the defect area and absence of functional disturbances related to palpebral position and closure. There were no cases of complete flap loss or partial flap necrosis. The only encountered complication was edema and flap congestion in one patient, solved by superficial pricking using a syringe needle.

The reconstruction results are best illustrated through the following cases that were selected from the study group (fig. 1-26).

Fig. 1. Clinical appearance of a BCC of the medial angle of left eye.

Fig. 2. Excision within oncologic safety margins. The defect was covered using a rotated frontal flap.

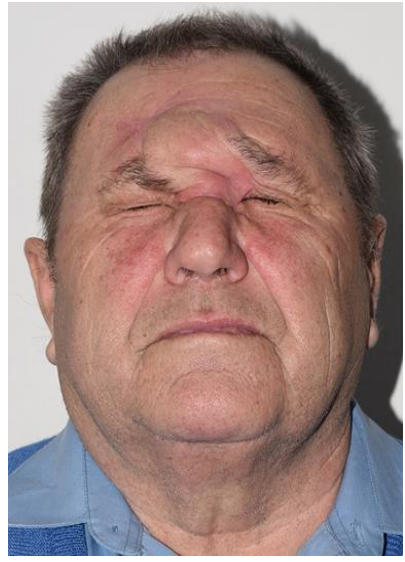

Fig. 3. One-year postoperative appearance proving the favorable functional outcome with accurate eyelid closure.

Fig. 4. One-year postoperative outcome showing the good appearance of the reconstructed area. Although the aesthetic appearance could have been improved, the patient did not want any further corrective surgery.

Fig. 5. Patient with a BCC of the right nostril.

Fig. 6. Intraoperative view of the defect following tumor removal and marking of the paramedian forehead flap.

Fig. 7. Intraoperative appearance of paramedian frontal flap sutured into the defect and closure of the donor area.

Fig. 8. Clinical appearance of the reconstructed area at one year after surgery showing the excellent cosmetic as well as functional outcome due to good nostril patency for an adequate air flow.

Fig. 9. Patient with a BCC of the left nasal-genian region.

Fig. 10. Picture demonstrating the superficial pricking of the island flap used for defect reconstruction. Superficial pricking was performed using a syringe needle during the first 5 days following the surgical procedure for flap decongestion.

Fig. 11. Clinical appearance of island flap reconstruction tunneled into the defect at one month after surgery showing the good functional outcome regarding eyelid closure. There is an obvious increase in volume of the inserted flap due to existing pressure on the return circulation (venous and lymphatic) of the buried flap pedicle.

Fig. 12. Frontal view of the patient one year after surgery proving improved appearance due to the flap volume reduction consecutive to the reestablishing of venous and lymphatic flow.

Fig. 13. Patient with a SCC of the nasal tip and bilateral cervical and intraparotid lymph node metastasis.

Fig. 14. Intraoperative view of the defect resulted after tumor removal and the marking of the paramedian forehead flap.

Fig. 15. Postoperative view at 6 weeks after complex surgery involving tumor resection and plasty with an Indian flap and bilateral neck dissection together with bilateral parotidectomy.

Fig. 16. Clinical appearance of the patient 5 years postoperatively showing the excellent esthetic outcome. The patient received chemotherapy and radiation therapy.

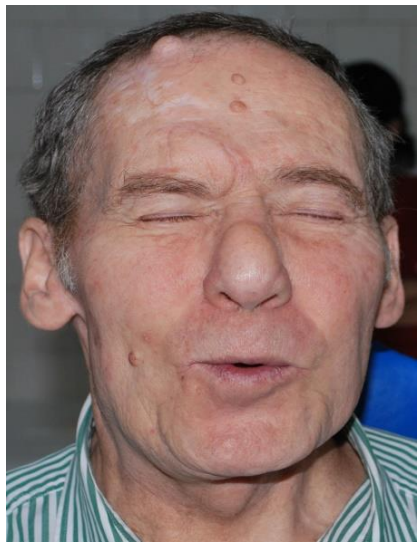

Fig. 17. Five-year postoperative outcome. The cosmetic result is very good and there are no signs of facial nerve damage.

Fig. 18. Patient with BCC recurrence in the left nasal-genian region following incomplete surgical excision done four years before he presented to our clinic with the recurrence.

Fig. 19. Intraoperative view of the resulting defect. A wide excision was performed. The histopathological examination confirmed clear margins in both surface and depth. For an optimal esthetic and functional result, the surgical defect was reconstructed separately for each of the two involved facial units: the nasal and the genian region.

Fig. 20. Intraoperative view of the Indian flap used for the plasty of the nasal and nasal-genian regions.

Fig. 21. Intraoperative aspect of the deep surface of the raised Indian flap.

Fig. 22. Intraoperative view of the left genian flap used for the plasty of the genian defect.

Fig. 23. Intraoperative view of the suspension sutures anchored to the inferior orbital rim used for reducing the tension in the genian flap.

Fig. 24. View of the performed reconstruction at the end of the surgical procedure.

Fig. 25. Frontal view of the patient four years after surgery showing the restored symmetry of the nasal and genian regions with an overall good esthetic outcome.

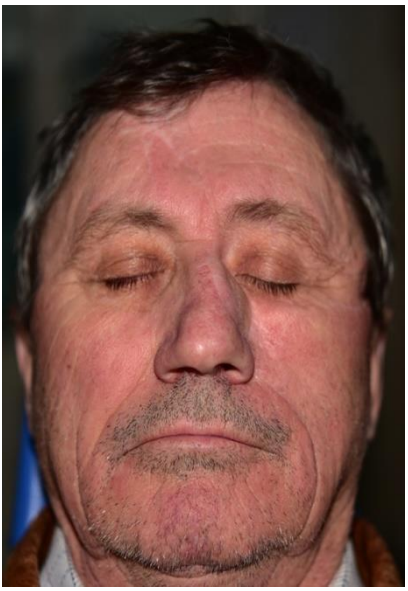

Fig. 26. Frontal view of the patient four years after surgery showing good eyelid closure.

DISCUSSION

The Indian flap (the para-median frontal flap) is an axial flap. The axial vascularization has been demonstrated by Kazanjian in 1930 and it consists of the median branch of the supraorbital artery and the supratrochlear artery. These vessels have a vertical trajectory emerging at 1.7-2.2 cm from the median line (9, 10), initially travelling sub muscular, and then, at approximately 1 cm above the eyebrow they become superficial, located in the subcutaneous tissue.

The Indian flap has undergone numerous innovations and modifications, becoming the first choice for the nasal defects. Although traditionally it is considered "the gold standard" for these sites, the indication has been extended to other sites on the face: the infraorbital region and the upper lip region. Any defect located above the lips or in the medial part of the cheek, may be covered using Indian flaps.

The technical details of the flap dissection are governed by certain principles for achieving viable flaps and good results. Maintaining the axial path is an important operative step, considering the known trajectory of the feeding arteries. The distal extremity of the flap can be extended on the forehead width when needed, but with unpredictable results. The pedicle has to be as narrow as possible avoiding the skin of the glabella, as the excessive bulk of the pedicle passing under the glabellar skin jeopardizes the blood supply and distorts the nasal contour (11). The supratrochlear pedicle can be as narrow as 1.0 to 1.2 cm (12, 13, 14). A subperiosteal dissection is performed at the base of the flap to protect

and include in the flap the initially deep arterial axis.

After extensive resections, especially in cases of recurrence, the frontal flap can be combined with other flaps for functional and cosmetic considerations. Indian flap reconstruction after excision of lesions located in the inner corner of the orbit or on the nasal wing may be difficult. For the medial corner of the eye, the functional result regarding eyelid closure has the same importance as the cosmetic result. When the resection of the nostril wall is wide, and a large part of the alar cartilage is also involved ear cartilage transplantation is needed. A small composite graft consisting of tegument and cartilage is taken from the auricle and used for reconstruction. If the permeability of the nostril is not affected by resection and/or its plasticity, the surgical defect can be covered in good conditions using the Indian flap.

Age is not a contraindication for the frontal flap reconstruction. In the cases presented, there are patients aged over 80 years with comorbidities in which the Indian flap has been safely performed. It is not necessary to modify patient's anticoagulation therapy prior to surgery.

The surgery can be performed under sedation but preferably under general anesthesia. Recurrence after excision of a malignant lesion is due to an imperfect technique. In these situations, the histopathological examination of the specimen reveals the surface margins, and/or the in-depth limits invaded by tumor tissue. Recurrence of BCC is less severe than recurrence of SCC. For recurrent BCC, a correct re-resection solves the problem for good, but for SCC recurrence the re-intervention is precious time lost since the disease usually progresses.

When the recurrence of the SCC develops under the flap, the clinical manifestations have a slower onset due to the thickness of the flap, which may contribute to the spread of the disease (15). To capture an eventual recurrence as early as possible (in unsafe cases and when the histopathological examination of the margin of the resection specimen is not possible), a total skin graft may initially be applied to a favorable receiving site. The skin of the auricular-cephalic groove (from the mastoid and posterior side of the ear) has the same color and texture as the facial skin and is a good option for full thickness skin graft elevation. The graft donor defect is easily covered by suturing the auricular margin at the mastoid edge with an invisible scar. The cosmetic result is often satisfactory, and the resolution can remain definitive. When there are functional or cosmetic reasons requiring a flap reconstruction, the re-intervention does not take place earlier than 6 months. Any recurrence developing during this time is easy to recognize at an early stage.

CONCLUSIONS

As demonstrated by the favorable results of our study, the Indian flap, with all the theoretical specifications and technical improvements over time, remains nowadays an up to date and useful technique in the reconstructive surgery of the face, just as described more than two millennia ago.

Originally, it was designed for the repair of the nasal pyramid, but the indications have been extended to cover defects with other locations on the face. With a correct indication, perfect flap planning, dissection and mobilization, we have found that the functional and cosmetic results can be among the best.

STUDIU PRIVIND INFLUENŢA FACTORILOR DE MEDIU ŞI INDIVIDUALI ÎN LITIAZA RENALĂ

L. Vasilescu, Al.D. Ciochină, C. Corciovă
Universitatea de Medicină şi Farmacie "Gr.T. Popa" Iaşi
Facultatea de Bioinginerie Medicală

STUDY ON THE INFLUENCE OF ENVIRONMENTAL AND INDIVIDUAL FACTORS IN RENAL LITHIASIS (Abstract): The large number of cases with renal lithiasis occurring in the population of the south-east region of Iasi county has determined us to make a study in this region for the identification of environmental and individual factors involved in the etiopathogenesis of this disease. This study is performed to assert the corelation between the clinical and paraclinical patients data with those obtained through water and soil chemical analisys for identification of determinant environmental and individual factors involved in etiopathogenesis of this disease. This study indicates that the environment factors (water, soil) correlated with personal factors, especially the diet and standard of living are the favouring factors of renal lithiasis. **Key words:** RENAL LITHIASIS, KIDNEY STONES, PROPHYLAXIS

Litiaza reno-urinară este consecinţa precipitării în tractul urinar a unor constituenţi care, în urina normală, se găsesc în soluţie fără tendinţă la precipitare. Principalele componentele urinare responsabile în procesul de litogeneză sunt: Ca^{2+}, P^{3+}, Mg^{2+}, oxalat, acid uric, uree, ioni de amoniu şi cistină (1). Urina elaborată de rinichiul normal reflectă starea fiziologică a organismului şi este un lichid supraconcentrat în cristaloizi pe care, însă, îi menţine în stare de soluţie datorită proprietăţilor sale fizico–chimice (1,2); ne referim în primul rând la pH, volumul urinar, concentraţia componenţilor urinari, dar şi la prezenţa unor inhibitori ai cristalizării magneziu, citratul, pirofosfatul, mucopolizaharizii acizi).

Există un context de factori fizici, chimici, metabolici, anatomici, bacteriologici şi de mediu care determină o concentraţie a sărurilor urinare peste punctul de saturaţie, cu formarea calculilor renali.

Mediul înconjurător intervine în mod categoric în geneza calculilor urinari prin deshidratare în atmosferă caldă şi uscată, ingestia de factori litogeni prezenţi în apă sau alimente (3).

Deshidratarea cu oligurie cronică, obiceiurile alimentare unilaterale cu exces proteic, tulburările metabolice (obezitate, denutriţie, gută, cistinurie, hiperoxalurie) tulburări de flux urinar şi încărcarea urinii cu cataboliţi microbieni în infecţiile urinare, medicamentaţie cu potenţial litogenic renal standardul de viaţă scăzut sunt cauze individuale favorizante ale litiazei renale.

Mecanismul de geneză a unui calcul reno-urinar este insuficient cunoscut. Cristalurie există în orice urină normală, dar pentru apariţia litiazei urinare manifestă clinic este necesară intervenţia unor factori multipli, dintre care mulţi rămân încă necunoscuţi (2).

Între stadiul de nucleere şi dezvoltare a calculilor urinari şi evidenţierea acestora întâmplător sau datorită complicaţiilor pe care le detemină, este o perioadă de timp suficient de lungă şi poate fi denumită faza activă metabolic a litiazei urinare (1).

Acest stadiu în care proprietăţile fizico-chimice ale urinii sunt propice litogenezei

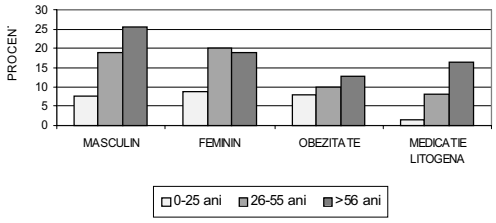

Fig. 1. Structura lotului investigat

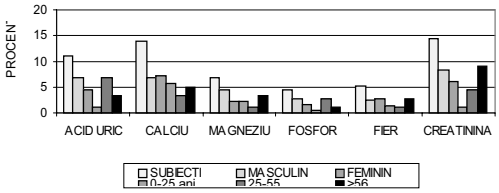

Fig. 3. Parametri biologici cu nivel plasmatic crescut

şi determinate de cauze complexe individuale sub influenţa favorizantă sau indiferentă a factorilor de mediu face obiectul studiului nostru.

MATERIAL ŞI METODĂ

Lotul selectat cuprinde 180 de locuitori ai localităţii Răducăneni aflaţi în evidenţa medicului de familie. Criteriile de selecţie a lotului investigat au avut în vedere circumstanţele de apariţie a litiazei renale şi anume influenţa factorilor individuali şi ai celor de mediu în etiopatogenia acestei afecţiuni. Interesul nostru de a surprinde litiaza renală în faza activă metabolic, ne-a determinat să structuram lotul în 3 categorii : indivizi până în 25 de ani, indivizi între 26 şi 55 de ani şi indivizi peste 55 de ani. In cazul antecedentelor personale am avut în vedere acele afecţiuni însoţite de excreţia în cantităţi anormale a componenţilor litogeni sau unele medicaţii practicate (4). O serie de boli transmise autozomal dominant sau recesiv cum sunt : acidoza tubulară renală, hipercistinuria, litiaza urică familială, hiperoxaluria congenitală, anomalii morfologice congenitale ale aparatului excretor au fost de asemenea luate în consideraţie (2). Alţi factori cum sunt : obiceiurile alimentare, ocupaţia, sedentarismul,

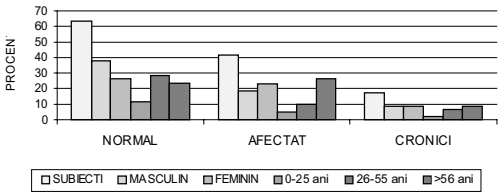

Fig. 2. Profilul metabolic

stressul, nivelul de trai, apartenenţa religioasă diferenţiază subiecţii investigaţi în grupe de risc (3).

Influenţele mediului extern au fost cercetate prin analiza compoziţiei chimice a apei de fântână şi a solului (3).

Aparatura folosită : analizor automat de biochimie AIRONE 200 RA, analizor automat hematologie Mindray, analizor ioni EASY LYTE Ca, microscop optic MICROS.

Investigaţiile de laborator au vizat aprecierea profilului metabolic general, examenul urinii şi dozarea constituenţilor biochimici care sunt implicaţi sau favorizează faza activă metabolic a litogenezei.

Analiza chimică a apei am efectuat-o la Institutul de Igienă „Mihai Ciucă”, Iaşi.

REZULTATE

Analiza rezultatelor obţinute s-a făcut după următoarele criterii :

1. Lotul investigat cuprinde 180 de subiecţi din mediu rural aflaţi în evidenţa medicului de familie : 52.22% subiecţi de sex masculin (7.77%, 0-25 ani, 18.88% 26-55 ani, şi 25.55% peste 56 ani) şi 47.78% subiecţi de sex feminin (8.89% subiecţi până în 25 de ani, 20% subiecţi între 26 şi 55 ani şi 18.89% subiecţi peste 56 de ani). Obezitatea este prezentă la 30.6% subiecţi, iar 16.6% subiecţi sunt subnutriţi. Medicaţie litogenă urmează 25.85% de subiecţi (fig. 1).

2. Profilul metabolic general a fost apreciat prin examene de laborator : hemoleucogramă – metoda Coulter, VSH, glucoză plasmatică şi urinară – metoda Trinder GOD--POD, uree plasmatică şi urinară - metoda urează-GLDH, creatinină plasmatică şi uri-

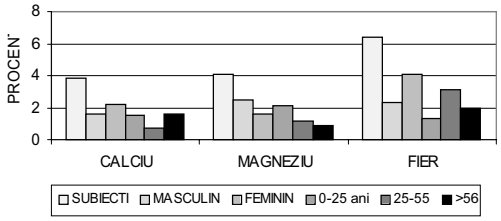

Fig. 4. Parametri biologici cu nivel plasmatic scăzut

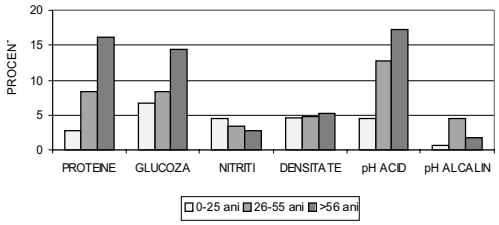

Fig. 5. Examen sumar urină

nară - metoda Jaffé, transaminaze GPT – metoda IFCC - LDH-NADH şi GOT – metoda IFCC - MDH-NADH, colesterol – metoda CHOD-POD, trigliceride - metoda GPO-POD, proteine totale – metoda biuret, fosfataza alcalină metoda p-nitrofenilfosfat, sumar urină şi sediment urinar.

Rezultatele se încadrează în intervalul de valori normale pentru 63.89% de subiecţi, 37.78% subiecţi de sex masculin (SM) şi 26.11% subiecţi de sex feminin(SF) : 11.67% 0-25 ani, 28.89% 26-55 ani şi 23.34% peste 56 ani.

În 41.67% din cazuri, 18.89% SM şi 22.77% SF (5% 0-25 ani, 10% 26-55 ani şi 26.67% peste 56 ani) subiecţii examinaţi prezentau o serie de afecţiuni acute (respiratorii, hepatice, digestive, renale) care au fost confirmate prin examen medical de specialitate.

17.23% de subiecţi, 8.34% SM şi 8.89% SF (2.23% 0-25 ani, 6.11% 26-55 ani şi 8.89% peste 56 ani) sunt bolnavi cronici de hipertensiune arterială, insuficenţă cardiacă, diabet zaharat, insuficenţă renală, infecţii cronice respiratorii, hepatice, renale) ; Aceşti subiecţi, prezenţi în evidenţa medicului de familie au fost investigaţi complementar pentru decelarea constantelor biologice favorizante sau determinante pentru litogeneza renală (fig. 2).

1. Investigaţiile de laborator în sânge şi urină pentru parametri biologici implicaţi în litogeneză : acid uric – metoda uricază–POD, calciu - metoda orto-cresolftaleină, fosfor - metoda cu molibdat de amoniu, magneziu - metoda cu calmagită, fier - metoda ferozină şi creatinina pentru aprecierea orientativă a funcţii excretorii renale.

a) Dozări plasmatice

Un nivel plasmatic crescut a fost decelat pentru (fig. 3) :

- acid uric, 11.1%, (8.34% SM, 8.89% SF, 2.23% 0-25 de ani, 6.11%, 26-55 ani şi 8.89% peste 56 ani) ;
- calciu, 13.9%, (6.67% sex masculin, 7.23% sex feminin, 5.56% 0-25 de ani, 3.34%, 26-55 ani şi 5% peste 56 ani) ;
- magneziu, 6.69%, (4.46% seSM, 2.23% SF, 2.23% 0-25 de ani, 1.12%, 26-55 ani şi 3.34% peste 56 ani) ;
- fosfor, 4.45%, (2.78% SM, 1.67% SF, 0.55% 0-25 de ani, 2.78%, 26-55 ani şi 1.12% peste 56 ani) ;
- fier, 5.12%, (2.43% SM, 2.69% SF, 1.31% 0-25 de ani, 1.2%, 26-55 ani şi 2.61% peste 56 ani) ;
- creatinină, 14.46%, (8.34% SM, 6.12% SF, 1.12% 0-25 de ani, 4.45%, 26-55 ani şi 8.89% peste 56 ani).

Nivel plasmatic scăzut a fost decelat pentru (fig. 4) :

- calciu, 3,8%, (1.67% SM, 2.2% SF, 1.5% 0-25 ani, 0,6%, 26-55 ani şi 1,6% peste 56 ani) ;
- magneziu, 4,1%, (2,5% SM, 1,6% SF, 2.11% 0-25 de ani, 1.12%, 26-55 ani şi 0,87% peste 56 ani) ;
- fier, 6,44%, (2.34% SM, 4,1% SF, 2,36% 0-25 ani, 3,1%, 26-55 ani şi 1,98% peste 56 ani).

b) Analiza urinii

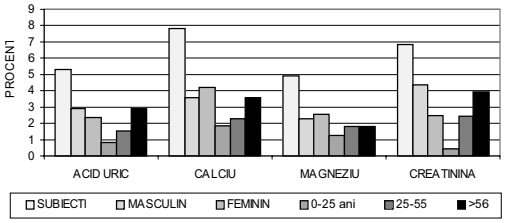

Fig. 6. Dozări biochimice în urină

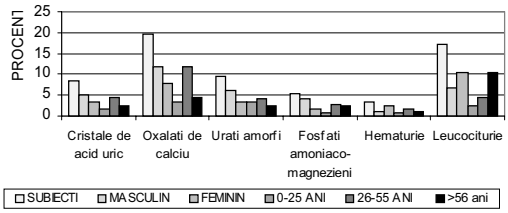

Fig. 7. Examenul sedimentului urinar

La examenul sumar de urina s-a constatat (fig.5) :

- proteinurie prezentă la 15% SM şi la 12.23% SF (2,78% 0-25 ani, 8.34% 26-55 ani şi 16.12% peste 56 ani) ;
- glicozurie prezentă la 13.89% SM şi la 15.86% SF (6,67% 0-25 ani, 8.34% 26--55 ani şi 14.45% peste 56 ani) ;
- nitriţi prezenţi la 5% SM şi la 5.56% SF (4.45% 0-25 ani, 3.35% 26-55 ani şi 2.78% peste 56 ani) ;
- densitatea urinară influenţată la 8.35% SM şi la 6.48% SF (4.72% 0-25 ani, 4.82% 26-55 ani şi 5.29% peste 56 de ani).
- pH-ul urinar este acid la 20.5% SM şi 13.9% SF (4.5% 0-25 ani, 12.8%, 26-55 ani şi 17.3% peste 56 ani) iar alcalin la 3.9% SM şi 2.8% SF (0.6% 0-25 ani, 4.5%, 26-55 ani şi 1.7% peste 56 de ani).

Valori crescute ale concentraţiei în urină s-a constatat pentru (fig. 6) :

- acid uric, 5.3%, (2.92% SM, 2.38% SF, 0.86% 0-25 ani, 1.54%, 26-55 ani şi 2.9% peste 56 ani) ;
- calciu, 7.8%, (3.57% SM, 4.23% SF, 1.87% 0-25 ani, 2.31%, 26-55 ani şi 3.62% peste 56 de ani) ;
- magneziu, 4.9%, (2.31% SM, 2.59% SF, 1.25% 0-25 ani, 1.83%, 26-55 ani şi 1.82% peste 56 ani) ;
- creatinină, 6.85%, (4.37% SM, 2.49% SF, 0.45% 0-25 de ani, 2.42%, 26-55 ani şi 3.98% peste 56 ani).

Examenul sedimentului urinar evidenţiază (fig.7) :

- cristale de acid uric, 8.34%, (5% SM, 3.34% SF, 1.67% 0-25 de ani, 4.45%, 26-55 ani şi 2.23% peste 56 ani) ;
- oxalaţi de calciu, 19.45%, (11.67% SM, 7.78% SF, 3.34% 0-25 ani, 11.67%, 26--55 ani şi 4.45% peste 56 ani) ;
- uraţi amorfi, 9.45%, (6.12% SM, 3.34% SF, 3.34% 0-25 ani, 2.89%, 26-55 ani şi 2.23% peste 56 ani) ;
- fosfaţi amoniaco-magnezieni, 5.56%, (3.89% SM, 1.67% SF, 0.56% 0-25 ani, 2.77%, 26-55 ani şi 2.23% peste 56 ani) ;
- hematurie, 3.34%, (1.12% SM, 2.23%

TABELUL I

Indicatori chimici de calitate a apei

SF, 0.56% 0-25 de ani, 1.67%, 26-55 ani şi 1.12% peste 56 ani);

- leucociturie, 7.23%, (6.67% SM, 10.56% SF, 2.23% 0-25 ani, 4.45%, 26 - 55 ani şi 10.56% peste 56 ani).

La 13.89% subiecţi investigaţi este prezentă infecţie urinară (5% SM, 8.89% SF, 1.12% 0-25 ani, 2.77%, 26-55 ani şi 10% peste 56 ani). 3.87% din subiecţi au infecţii urinare repetate.

4. Indicatori chimici de calitatea apei: apa este dură, bicarbonatată cu un conţinut apreciabil în săruri minerale (tab.1).

5. Compoziţia chimică a solului - Indicele Hlebnicov de 0,79 arată o poluare medie a solului.

CONCLUZII

O primă concluzie în acest stadiu al studiului ar fi că factorii de mediu studiaţi (apă, sol) corelaţi cu cei personali, în special obiceiurile alimentare şi nivelul de trai sunt factorii favorizanţi ai litiazei reno- urinare.

21 de subiecţi din lotul studiat prezintă risc litogenic renal crescut şi au fost incluşi în programe de monitorizare.

Considerăm că educaţia sanitară în cadrul colectivităţii ar reprezenta una dintre primele măsuri de prevenţie pentru litiaza renală.

Necesitatea adoptării unor măsuri de protecţie a mediului prin programe de identificare şi neutralizare a factorilor poluanţi.

THE SUCCESS RATE OF TWO TYPES OF ORTHODONTIC BONDED RETAINERS (Abstract) **Aim**: The aim of this prospective clinical study was to compare the success rate of two types of fixed orthodontic retainers, flat and round wires. **Material and methods:** 53 patients aged between 11 and 53 years old were included in this study. The patients' orthodontic treatment history was bimaxillary fixed appliances for all kind of dento-maxillary malocclusions. The patients were sequentially assigned to receive round or flat retainers. **Results:** No debonding in the first year was considered a success. Retainer failures were monitored and centralized. A statistical test evaluated the success rate by comparing the two types of retainers according to age, gender, and location. **Conclusions:** Bonded retainers maintain incisor alignment following orthodontic treatment. A significant correlation between age and success rate of the flat wire and the round wire retainer was found (p=0.035). The configuration and type of wire have an important role in the failure rate. The success rate of round wire retainer was higher on females and the flat retainers had a greater success on males. **Keywords**: ORTHODONTICS, CONTENTION, ALIGNMENT, RETAINER.

The stability of orthodontic treatment has always been an issue, especially in cases with crowding in the inferior labial segment. There have been numerous studies which revealed relapse cases after aligning the frontal inferior teeth (1). To avoid relapse, every orthodontic treatment is followed by a contention phase. In practice, removable or fixed retainers are used. Nowadays orthodontic mandibular canine to canine retainers are frequently used. The major advantage of the bonded retainer compared to the removable one is that it doesn't need compliance, excepting oral hygiene procedures. One of the studies showed that almost one-third of American orthodontists usually use fixed retainers, representing a bigger proportion than previous reports (2).

Several studies proved that 10 years later after finishing the orthodontic treatment, relapses were found in 40-90% of cases (3). On the other hand, the stability of orthodontic results could last for more than 20 years in 10% of cases (4).

Ten years after orthodontic treatment,

30-50% of patients have the satisfaction of maintaining dental alignment, but after 20 years the percentage drops to 10 %. When relapse occurs, there some efficient strategies are necessary. The treatment methods of solving relapse should be different from the initial treatment, because the periodontal status, the physiological and psychological status are different too. Controlling the relapse is important to avoid wasting time, money and resources to redo the dental alignment (5).

Fixed lingual retainers bonded to mandibular anterior teeth have been introduced in 1970's by Knelrim (6), and have been considered part of the orthodontic treatment, for avoiding relapse or secondary crowding of inferior incisors (7). Hawley introduced the removable retainer: the Hawley removable appliance, an acrylic appliance (8, 9).

The first generation of fixed retainers were made of stainless-steel round wire, with large diameter: 0.030-0.032 inch; they were followed by smaller diameters or coaxial round wires or cross-section rectangular wires having different compositions, bonded on the lingual part of the anterior mandibular teeth. Recently, fiber-reinforced materials and alumina ceramic retainers have been introduced (10, 11).

The conclusion of most orthodontists is that the most efficient method to avoid relapse and secondary crowding of the inferior and superior frontal teeth is the fixed retainer. Because the removable retainers need patient compliance, the golden standard for contention is the fixed retainer.

Zachrisson introduced in 1983 the lingual retainer made of round wire, but nowadays there are many types of wires and diameters and methods of bonding fixed retainers (12, 13, 14).

AIM

The aim of this study was to compare the success rate and debonding rate of 2 types of fixed multistranded retainers: one round 0.0175-inch diameter wire and another flat wire: 0.010 x 0.022 inch. The criterion for evaluating success was: the absence retainer debonding after at least one year from applying it in the oral cavity.

MATERIAL AND METHODS

A number of 53 patients aged between 11 and 53 were included in this study, 33 of them wearing round fixed retainers (fig. 1), and the other 20 flat wire retainers (fig. 2).

The patients' orthodontic treatment history was bimaxillary fixed appliances for all kind of dento-maxillary malocclusions.

The patients were elected from a private clinic from Tîrgu-Mures. History dental files have been used as material to obtain necessary data for our study:

- the total number of patients;
- age;
- gender;
- the type of retainer that has been used (flat or round);
- the retainer's position, lower canine to canine, upper lateral incisor to lateral incisor;
- the date of retainer bonding;
- the date of the first retainer debonding.

The including criteria were:

- fixed orthodontic treatment in history;
- dental alignment and stable occlusion at the end of the orthodontic treatment;
- the possibility of using fixed retainers for upper and lower jaw at the end of the treatment.

The method for applying the retainer included the next steps:

- isolation with rubber dam from the second premolar to the second premolar;
- cleaning the dental surfaces using a brush and a fluoride-free toothpaste;
- fixing the retainer using dental floss (fig. 1 a and b);
- etching using phosphoric acid 37% (fig. 2 a) (15);
- bonding using a special adhesive material (fig. 2 b);
- fixing retainer with a special flowable composite (fig. 3).

The retainers were fixed from canine to canine at the lower jaw and lateral incisor to lateral incisor in the lower jaw. The only difference was the type of multistranded wire: the flat retainer with wire dimensions of 0.010x0.022 inch and the round retainer with 0.0175-inch diameter wire.

The success rate was statistically monitored comparing the two types of retainers by age, gender, and location. The statistical analysis included the descriptive statistics to determine the average value and the chi-squared test to establish the correlation between the age or gender of the patient and the success rate.

The Mantel-Cox log-rank test was used to identify significant differences in survival functions among the groups.

RESULTS

A number of 53 patients aged between 11 and 53, 33 females and 20 males were included in the study. A number of 43 retainers on the inferior arch and 37 on the superior arch have been applied. Table 1 shows the success rates of the two types of retainers according to the variables. Overall, significantly ($p< 0.035$) more failures in the multistrand round retainers' group were observed in comparison with the flat multistrand retainers' group (tab. I). According to location, the flat retainers were more successful in the upper arch comparing with the lower arch, but the difference was not statistically significant ($p=0.06$). On the other hand, the round retainers have a significantly lower success rate in the upper jaw comparing to the lower one.

A success rate of 64 % in females with flat wire retainer was observed; in 5 out of 14 patients, retainer detachments were recorded. For the round wire retainers, there has been a rate of success of 86 %, 3 out of 19 patients had retainer detachment. The success rate in males was 80 % for the flat wire retainer when 1 out of 5 patients had a failure. And for the round wire, the success rate was 73%, recording 4 failures out of 15 cases.

TABLE I

The success rate of two types of retainers according to multiple variables: gender, age, location, and general success rate

	Group	Gender		Age		Location		General
		Female	Male	11-18	19-53	Upper	Lower	
Success	Flat retainer	9 (64%)	4 (80%)	8 (62%)	5 (83%)	10 (67%)	9 (64%)	13 (68%)
	Round retainer	16 (84%)	11 (73%)	11 (83%)	16 (76%)	17 (77%)	24 (83%)	27 (79%)

The chi-squared test results demonstrated a significant statistic correlation between the age and the success rate of the round wire and flat wire retainer ($p=0.035$).

DISCUSSION

This study on the success rate of the bonded retainers appears to be the first in the central part of Romania. It was aimed to compare two types of retainers flat and round wire, according to patient gender and age and retainer position.

The general success rate was 68% for the flat wire retainer and 79% for the round wire retainer. This finding is in accordance with the results of Årtun *et al*. (16) and Segner and Heinrici (17).

Analyzing the success rate according to the location of the retainer, the results for the inferior arch showed a success rate of 64% for the flat retainer and 83 % success rate for the round wire. In the upper arch, there has been found a 67% success rate for the flat retainer and a 77% success rate for the round retainer. The failure rate for mandible retainers was lower than the findings of Andrén *et al.* (18) who reported a failure rate of 35% for the mandible. Störmann and Ehmer (19) reported a similar failure rate of 18 % for the 0.0195-inch retainer. The higher success rate might be explained by the use of rubber dam for isolation. Similar studies (Dahl and Zachrisson, 1991 (7); Bearn, 1995 (20); Andrén *et al.*, 1998 (18); Segner and Heinrici, 2000 (17)) have shown higher failure rates for the maxilla compared with the mandible.

The failure rate according to the type of

retainer was between 16-27% for round retainer, smaller than flat retainer 17-38% and comparable with the findings of Årtun *et al.* (16), 27.2 % for the thin, flexible spiral wires. On the other hand, Dahl and Zachrisson reported a smaller failure rate of 10.3% for three-stranded spiral wires and 5.9% with the five-stranded spiral wire (7).

According to patient gender, a success rate of 64% in females with flat wire retainer and 86% with round retainers was observed. The success rate in males was 80 % for the flat wire retainer and 73% for the round wire. These indicated a lower failure rate for flat retainers on males and a lower failure rate for round retainers on females. Lumsden *et al.* (21) study did not show significant differences in failure rate according to gender and age.

The results related to age showed a higher success rate for the round retainer considering both samples: age between 11-18 and 19-53. A slightly increased failure rate was found regarding the patients aged between 11-18 in agreement with the findings of Lumsden *et al.* (21) where the mean age of the subjects was 15.5 years. However, the results were lower than those reported by Dahl and Zachrisson (1991) where the mean age of the patient population was 31.2 years (7).

Although previous investigations (Dahl and Zachrisson, 1991 (7); Årtun *et al.*, 1997 (16); Störmann and Ehmer, 2002 (19); Tacken, 2010 (10); Foek, 2009 (22); Salehi, 2013 (1)) have shown a difference in failure rate when different types of retainers are used. Salehi (2013) showed no significant differences between the wire retainer and the polyethylene fiber retainers for both arches. Tacken (2010), demonstrated that the glass fiber reinforced retainers (GFR) had a lower success rate than the stainless-steel wire retainer. Foek (2009) results were that the stainless-steel wire retainer had greater success than the fiber reinforced retainer.

In other similar studies (Dahl and Zachrisson, 1991 (7); Årtun *et al.*, 1997 (16)) the retainer wires were bonded with chemically polymerized resin composite. The survival rate also depends on the bond strength of the orthodontic materials, Martha K. *et al.* 2013 (23). In the current study, isolation was achieved using rubber dam, according to Audenino *et al.*, 2006 the survival rate of resin-bonded restorations has been higher using rubber dam isolation. In this study, the success rate has been increased by using absolute isolation (24).

Future prospective studies should concentrate on factors such as isolation control, the light intensity of the polymerization device and the composite and adhesive resin used.

CONCLUSIONS

Bonded retainers maintain incisor alignment following orthodontic treatment.

According to statistical data, a significant correlation between age and success rate of the flat wire and the round wire retainer was found, with a p-value < 0.05, $p=0.035$.

The failure causes of wire retainers included fractures, debonding and accidental detachment.

The configuration and type of wire have an important role in the failure rate. The round wire success rate is bigger than the flat retainer success rate. In both cases, there is an average rate of success higher than 60%.

The failure rate of flat retainers is lower on patients aged between 19-53.

On females, the success rate of round wire retainer was higher, and on males, the flat retainers had a greater success.

CLINICAL EPIDEMIOLOGICAL RETRO PROSPECTIVE STUDIES ON THE INCIDENCE AND PREVALENCE OF CARDIAC CONGENITAL ABNORMALITIES IN A GROUP OF 1570 CHILDREN, BORN IN IAŞI BETWEEN 2000 - 2009 (Abstract): **Material and method**: The study has been conducted on a period of ten years and it included 1570 children with congenital abnormalities (CA), of which 371 (24%) were cardiac abnormalities, 312 (20%) were skeletal abnormalities, 55 (3%) were Down Syndrome and 832 (53%) were other pathologies. **Results**: 48% of the 371 children that were diagnosed with cardiac CA were males, while 52% were females; 52% of the children were from the city, while 48% were from the country-side; 42% of the children have been born prematurely, while 58% of them have been born at normal term. 38% of the children had an APGAR score lower than 7 and 62% of them had an APGAR score higher than 7. Of the total number of births, 72% were caesarian births and 28% were natural births. The different types of Cardiac CA that have been encountered in the study were atrioventricular canal (56%), transposition of the great vessels (18%), common arterial trunk (10%), atrial septal defect (8%), ventricular septal defect (5%) and tetralogy of Fallot (3%). 66% of the total number of deaths were represented by those with cardiac pathology, 21% were caused by hydrocephalus, 7% were caused by diaphragmatic hernia, 4% had renal CA, while 2% were caused by other pathologies. **Key words**: CARDIAC CONGENITAL ABNORMALITIES, PREVALENCE, PREVENTION

Malformaţiile cardiace congenitale (MCC) reprezintă anomaliile structurale cu perturbări funcţionale ale inimii prezente la naştere, ca rezultat al unei alterări a dezvoltării embriologice cardiovasculare, apărute în perioada cardiogenezei (1,2).

Majoritatea MCC îşi au originea în morfogeneza anormală a tubului cardiac primitiv în primele 50 de zile ale vieţii embrionare (3).

Există relaţii strânse între modificările structurale şi funcţia cardiovasculară, iar trecerea de la circulaţia fetală la cea a nou-născutului ameliorează sau agravează unele MCC (4).

Grupul de studiu EUROSCAN a evidenţiat că rata diagnosticului prenatal al malformaţiilor congenitale variază foarte mult în

TABELUL I
Distribuţia cazurilor de malformaţii congenitale, înregistrate la Spitalul Clinic „Cuza Vodă", Iaşi, în perioada 2000-2009

Anul	Nr. Cazuri	Cardiace		Scheletice		Sindrom Down		Altele	
		Nr.	%	Nr.	%	Nr.	%	Nr.	%
2000	11	4	36	3	28	0	0	4	36

(*) Pentru valori mai mici de 10, proporţiile sunt orientative.

funcţie de frecvenţa efectuării screening-ului ecografic fetal (5).

În ţările cu experienţă în supravegherea ecografică a sarcinii s-a ajuns la concluzia că registrul de MCC nu aduce date suficiente privind valorile de prevalenţă deoarece unele cazuri subclinice rămân nediagnosticate (bicuspidia valvelor aortice), altele nu sunt înregistrate (malformaţiile grave care au determinat moartea intrauterină a fătului), iar diagnosticul prenatal a condus la întreruperea sarcinilor cu feţi suferind de MCC cu rezultate terapeutice incerte (sindromul de cord stâng hipoplazic). Cu toţi aceşti factori care influenţează prevalenţa MCC, indiferent de locul unde s-a evaluat, aceasta pare să fie de 5-8/1000 naşteri (5).

În România, absenţa efectuării, prin program, a screening-ului ecografic fetal, creează dificultate în a cunoaşte rata diagnosticului prenatal al malformaţiilor congenitale (6).

Astfel se estimează că se nasc anual, aproximativ 1.500-1.600 de copii cu MCC, dintre care, 850-950 necesită corecţie chirurgicală. Doar 30% din cazuri sunt rezolvate în România (7).

MATERIAL ŞI METODĂ

Cercetările au inclus 1570 de copii diagnosticaţi cu malformaţii congenitale (Mcg) în Maternitatea „Cuza Vodă" din Iaşi, în perioada 2000-2009.

Culegerea informaţiilor s-a realizat prin colaborarea cu serviciile de statistică medicală ale clinicii şi prin studierea registrelor de evidenţă a copiilor cu Mcg, din cadrul secţiei de neonatologie.

Cazurile incluse în studiu au fost analizate în raport cu: sexul, mediul de provenienţă (rural, urban), felul naşterii (naturală, cezariană), greutatea la naştere (<2700 g, >2700 g), vârsta gestaţională (<37 săptămâni, >37 săptămâni) şi scorul APGAR (<7, >7), urmat de evidenţierea ponderii fiecărui tip MCC şi decesele induse de acestea.

Prelucrarea şi interpretarea rezultatelor s-a realizat prin metode epidemiologice, clinice, statistico-matematice şi computerizate.

REZULTATE ŞI DISCUŢII

1. Ponderea MCC din totalul Mcg raportate la maternitatea "Cuza Vodă" Iaşi, în perioada 2000-2009.

În cei 10 ani luaţi în studiu au fost raportate 1570 cazuri de Mcg, dintre care 371 (24%) cardiace, 312 (20%) scheletice, 55 (3%) sindrom Down şi 832 (53%) alte patologii. S-a constatat o preponderenţă anuală a MCC. Astfel, am observat că cele mai multe afecţiuni de natură cardiacă au fost înregistrate în anul 2000 (36%) şi în 2008 (34%), pentru ca în ceilalţi ani prevalenţa

cazurilor să înregistreze valori de 20%.

Raportându-mă la Mcg scheletice, acestea ocupă un loc imediat următor celor cardiace, însumând 20% din total, cu un maxim în anul 2000 (28%) şi un minim în 2009 (6%). Cele mai frecvente au fost displaziile congenitale de şold, piciorul strâmb congenital şi polidactilia sau sindactilia. Sindromul Down a înregistrat o creştere a prevalenţei în anii 2001(8%) şi 2009 (12%). Printre celelalte Mcg înregistrate, în ordinea frecvenţei s-au situat : hidrocefalia, cele renale, herniile diafragmatice (tab. I).

2. Repartiţia pe sex şi mediul de proveniență.

În cei 10 ani luaţi în studiu, din cei 371 de copii cu MCC, 194 (52%) au fost de sex feminin şi 177 (48%) masculin, 194 (52%) proveneau din mediul urban şi 177 (48%) din rural (tab. II).

3. Analiza repartiţiei în relaţie cu greutatea înregistrată la naştere şi vârsta gestaţională.

Din totalul de 371 de copii diagnosticaţi la naştere cu MCC, am observat că 205 (55%) au avut o greutate < 2700 grame, cu o prevalenţă crescută in anul 2008 (37%). Din cei 166 (45%) care au avut o greutate > 2700 grame, s-a înregistrat o creştere semnificativă în anul 2001 (90%).

În aceeaşi perioadă de 10 ani, 154 (42%) din copii au fost prematuri (< 37 de săptămâni) şi 217 (58%) cu naşteri la termen (> 37 de săptămâni). Cele mai multe cazuri de prematuritate s-au înregistrat în anul 2006 (69%) şi cele mai puţine în 2004 (20%), iar pentru copiii născuţi la termen valorile prevalenţei au fost de 31% în anul 2006 şi 80% în 2004 (tab. III).

3. Repartiţia în funcţie de felul naşterii şi scorul APGAR acordat la naştere.

Luând în consideraţie evaluarea medicală a nou-născutului la 60 de secunde după expulzie, care apreciază respiraţie spontană, frecvenţa cardiacă, culoarea tegumentelor, excitabilitatea reflexă şi tonusul muscular, au fost analizate nivelurile Scorului Apgar.

În cazul nostru copiii care de la naştere au prezentat suferinţă fetală (APGAR <7), au înregistrat o prevalenţa de 10 % în anul 2001 şi 64 % în 2004.

Din totalul copiilor diagnosticaţi cu MCC, 267 (72%) au fost născuţi natural, iar 104 (28%) prin cezariană, diferenţa fiind puternic semnificativă ($p<0,005$), deoarece în anul 2003 s-au înregistrat 92% de naşteri naturale şi 8% prin cezariană. Totuşi, în anul 2008, prevalenţa naşterilor prin cezariană a fost de 73% faţă de 27% cea a naşterilor naturale ($p=0,05$).

TABELUL III

Distribuţia anuală, în raport de greutatea la naştere şi vârsta gestaţională a cazurilor de malformaţii congenitale cardiace, raportate la Spitalul Clinic „Cuza Vodă", Iaşi, în perioada 2000-2009

Anul	Nr. Cazuri MCC	Greutate la naştere (gr.)				Vârstă gestațională (săpt.)			
		< 2700		> 2700		< 37		> 37	
		Nr.	%	Nr.	%	Nr.	%	Nr.	%
2000	4	2	50	2	50	2	50	2	50
2001	20	2	10	18	90	8	40	12	60
2002	31	6	19	25	81	11	35	20	65
2003	36	7	19	29	81	11	31	25	69
2004	45	3	7	42	93	9	20	36	80
2005	49	4	8	45	92	28	62	21	38
2006	55	18	33	37	67	38	69	17	31
2007	81	18	22	63	78	26	32	55	68
2008	49	18	37	31	63	21	43	28	57
2009	1	0	0	1	100	0	0	1	100

(*) Pentru valori mai mici de 10, proporţiile sunt orientative

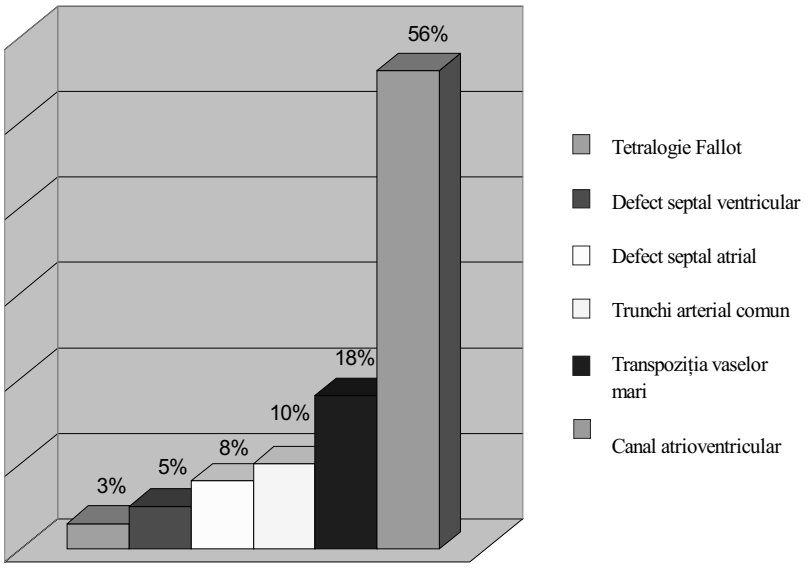

Fig. 1. Repartiţia pe tipuri a malformaţiilor congenitale înregistrate în serviciul de neonatologie al Spitalul Clinic „Cuza Vodă", Iaşi, în perioada 2000-2009

4. Distribuţia cazurilor de malformaţii congenitale cardiace în relaţie cu natura acestora.

Cele mai frecvente cazuri de MCC studiate în cei 10 ani, au fost: canal atrioventricular (56%), transpoziţia vaselor mari (18%), trunchi arterial comun (10%), defect septal atrial (8%), defect septal ventricular (5%) şi Tetralogia Fallot (3%)(Fig.1).

6. Decesele înregistrate la copiii cu malformaţiilor congenitale.

Din totalul deceselor înregistrate în cei 10 ani, majoritatea au fost reprezentată de cele cu patologie cardiacă (66%), urmate

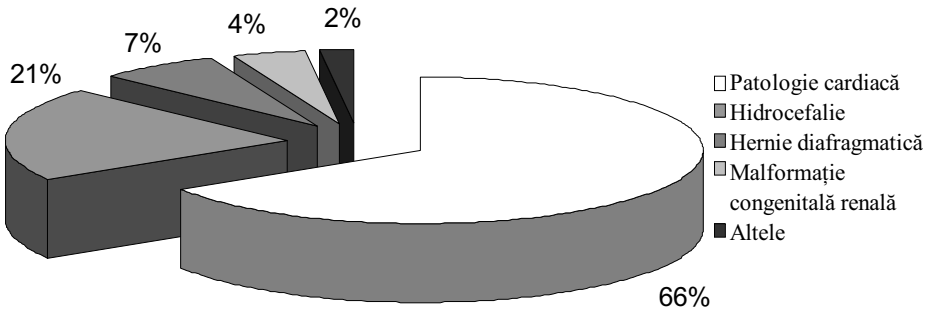

Fig. 2. Frecvenţa deceselor în cazul copiilor cu malformaţii congenitale înregistrate în serviciul de neonatologie al Spitalul Clinic „Cuza Vodă", Iaşi, în perioada 2000-2009

de hidrocefalie (21%), hernie diafragmatică (7%), malformaţie congenitală renală (4%) şi altele (2%) (Fig. 2).

CONCLUZII

În perioada 2000-2009 au fost înregistraţi 1570 copii cu malformaţii congenitale, dintre care 371 (24%) cardiace, 312 (20%) scheletice, 55 (3%) sindrom Down şi 832 (53%) alte patologii.

Din cei 371 de copii diagnosticaţi cu MCC, 48% au fost de sex masculin si 52% de sex feminin, 52% din mediul urban şi 48% din rural. S-a evidenţiat o prevalenţă de 42% în cazul naşterilor premature, 58% la termen; 55% copii cu greutate < 2700 grame şi 45% copii cu greutate > 2700 grame; scorul APGAR acordat la naştere a fost de 38% în cazul celor cu o valoare < 7 şi de 62 % la cei cu valoare > 7; din totalul naşterilor 72% au fost naturale şi 28% prin cezariană.

MCC mai frecvent întâlnite printre cazurile studiate, au fost: canal atrioventricular (56%), transpoziţia vaselor mari (18%), trunchi arterial comun (10%), defect septal atrial (8%), defect septal ventricular (5%) şi Tetralogie Fallot (3%). Din totalul deceselor înregistrate în cei 10 ani, 66% au fost cele cu patologie cardiacă, 21% hidrocefalie, 7% hernie diafragmatică, 4% malformaţie congenitală renală şi 2% altele.

MORUSIN AND KUWANON G-PROMISING ANTI-MRSA AGENTS (Abstract): Synergy between natural products and antibiotics represent a promising strategy in the development of new antimicrobial therapies. **Aim:** The present work investigated possible synergistic interactions between prenylated flavones morusin and kuwanon G and antibiotics (tetracycline, ciprofloxacin) against methicillin-resistant *Staphylococcus aureus* (MRSA). **Material and Methods**: The minimum inhibitory concentrations (MICs) of prenylated flavones and antibiotics against MRSA (MRSA ATCC 33591 and four MRSA isolates of animal origin) were determined by the broth microdilution method. The interactions between prenylated flavones and antibiotics were evaluated by the checkerboard and time-kill assays. **Results:** In the broth microdilution assay, morusin and kuwanon G showed very good antibacterial activity (MICs ranging 3.13 and 12.50 µg/mL). The checkerboard assay demonstrated that morusin and kuwanon G act synergistically with both antibiotics; significant reductions in antibiotic MICs (2 to 512-fold) were recorded. The time-kill assay (at ½MIC) indicated bactericidal synergy for the combinations of morusin or kuwanon G with ciprofloxacin against *S. aureus* ATCC 33591. **Conclusions:** The combination of morusin or kuwanon G with antibiotics are good candidates for the development of novel treatments for MRSA infections in humans and animals. **Keywords**: METHICILLIN – RESISTANT *STAPHYLOCOCCUS AUREUS*, SYNERGY, ANTIBIOTICS, MORUSIN, KUWANON G.

Nowadays the treatment of infectious diseases has to overcome a serious problem – antibiotic resistance. One great concern is methicillin-resistant *Staphylococcus aureus* (MRSA) due to its resistance to beta-lactams, including cephalosporins, but also aminoglycosides, macrolides, tetracyclines and fluoroquinolones (1, 2, 3).

MRSA transmission from animals to humans and *vice versa* is of great interest (4, 5). Considering the human exposure to livestock (6) and pet animals (7), but also the consumption of animal products (8), many researches focused on animals as sources of antimicrobial-resistant bacteria (9). The potential transfer of resistance genes from animals to humans is facilitated by the irrational antibiotic use not only for

medical purpose (treatment of animal infections), but also for growth promotion and prophylactic purposes (sub-therapeutic antibiotic doses) (10). In both humans and animals, MRSA strains are difficult to treat pathogens.

A promising strategy in the management of MRSA infections is the synergism between natural products and conventional antibiotics (11).

The present work investigated possible synergistic interactions between two prenylated flavones, morusin (MO) and kuwanon G (KG), and tetracycline (TE) or ciprofloxacin (CIP) against MRSA strains. Both prenylated flavones (fig. 1) are active constituents of *Morus* spp. (mulberry) and antioxidant (12), anti-inflammatory (13) and antibacterial (14, 15) activities have been reported for them.

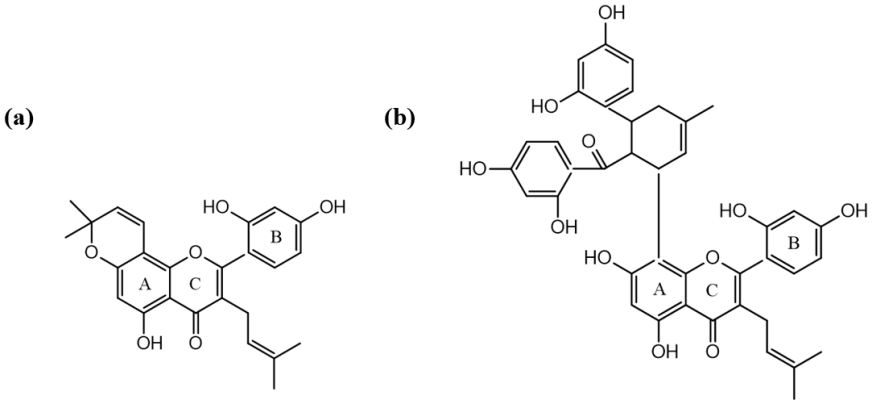

Fig. 1. Morusin (a) and kuwanon G (b)

MATERIAL AND METHODS

Methicillin-resistant *S. aureus* ATCC 33591 strain and four MRSA isolates (MRSA T1–T4) collected from various infections (recurrent otitis, pyoderma, laryngo-pharyngitis) in dogs were used in this study. The isolates were identified and characterized phenotypically by culture, hemolysis, catalase and coagulase tests and other enzymatic tests; their identity was confirmed by molecular tests (Polymerase Chain Reaction) (16). Minimum inhibitory concentrations (MICs) of prenylated flavones and antibiotics were determined by the broth microdilution method according to Clinical and Laboratory Standards Institute (CLSI) (17) and European Committee on Antimicrobial Susceptibility Testing (EUCAST) guidelines (EUCAST) (18). Checkerboard method (19) and time-kill assay (20) were performed in order to evaluate the interactions between prenylated flavones and antibiotics.

The results in checkerboard method were interpreted on the basis of the fractional inhibitory concentration index (FICI) values, isobolograms and response surface approach (ΔE model) (19). For each combination, FICI was calculated as follows: $FICI = FIC_{antibiotic} + FIC_{prenylated\ flavone}$ where $FIC_{antibiotic} = MIC_{antibiotic\ in\ combination\ with\ prenylated\ flavone} / MIC_{antibiotic\ alone}$ and $FIC_{prenylated\ flavone} = MIC_{prenylated\ flavone\ in\ combination\ with\ antibiotic} / MIC_{prenylated\ flavone\ alone}$.

A combination is deemed to have a synergistic effect if $FICI \leq 0.5$, additive effect if $0.5 < FICI \leq 1$, indifferent effect if $1 < FICI \leq 4$ and antagonistic effect if $FICI > 4$ (20).

In isobolograms, FIC values of antibiotics and prenylated flavones were represented on the *x* and *y* axis, respectively. The type of interaction is defined depending on the area the ratio points fall in. Synergistic, additive and indifferent interactions are expressed if the ratio points fall below the 0.5 : 0.5, 1 : 1 and 4 : 4 lines, respectively. The ratio points falling above the 4 : 4-line express antagonistic interactions (11).

The results of the checkerboard assay were also interpreted using the response surface approach (ΔE model) which compares the experimental data with theoretical data (predictive data) indicating the statistical significance of the interactions (19, 21).

The time-kill assay was performed for the combinations showing synergistic interactions in the checkerboard assay; the prenylated flavones and antibiotics were tested alone and in combination at sub-inhibitory concentrations (½MIC). The bacterial colonies (CFU/mL) were counted after 0, 4, 24 and 48 hrs. incubation at 37°C. An interaction is defined synergistic if the increase in bacterial killing induced by the combination in comparison to the most active component of the combination, tested alone, after 24 hrs. incubation (ΔLC_{24}), expressed as log10 CFU/mL, is equal or higher than 2 ($\Delta LC_{24} \geq 2$ log10 CFU/mL). Addition, indifference and antagonism are expressed if $\Delta LC_{24} = 1 - 2, \pm 1$ and > -1 log10 CFU/mL, respectively (22). Killing curves were also represented by plotting the viable colony counts (log10 CFU/mL) against time.

RESULTS AND DISSCUSION

In this study, both MO and KG showed very good antibacterial activity against *S. aureus* ATCC 33591 with MIC values of 6.25 and 12.50 µg/mL, respectively. In previous investigations, we assessed the antibacterial effects of MO and KG against MRSA T1 – T4 isolates and found MIC values ranging from 3.13 to 12.50 µg/mL (23, 24).

TABLE I
The median values of MIC (µg/mL) for antibiotics and susceptibility* of bacterial strains

Strain	MIC_{CIP}	Susceptibility to CIP	MIC_{TE}	Susceptibility to TE
S. aureus ATCC 33591	0.50	S	128	R
MRSA T1	0.25	S	0.25	S
MRSA T2	0.13	S	16	R
MRSA T3	0.50	S	2	S
MRSA T4	0.50	S	32	R

*according to CLSI 2017; CIP – ciprofloxacin, TE – tetracycline, (S) – susceptible, (R) – resistant

The antibacterial effects of prenylated flavones in combination with antibiotics were further evaluated using the checkerboard method. According to FICI interpretation, combinations of MO or KG with TE showed synergistic and additive interactions against *S. aureus* ATCC 33591 and MRSA isolates (tab. II and III). The corresponding isobolograms are depicted in figure 2a and 2b. According to CLSI susceptibility breakpoints, S *aureus* ATCC 33951, MRSA T2 and T4 isolates proved to be resistant to TE (tab. I). It is worth mentioning that KG reversed TE resistance of *S. aureus* ATCC 33591 and MRSA T4, whereas MO reversed TE resistance of MRSA T2; in combination with prenylated flavones, MIC of TE was decreased below the CLSI susceptibility breakpoint of 4 µg/µL (17). The prenylated flavones increased the susceptibility to TE of MRSA T1 and T3 causing 2 to 4-

fold reduction in MIC value of TE. With respect to combinations with CIP, MO and KG showed synergistic and additive interactions; the prenylated flavones increased susceptibility of all strains causing 2 to 16-fold reduction in MIC of CIP (tab. II and III; fig. 2c and 2d).

All synergisms found by FICI interpretation were confirmed by ΔE model. The additive interactions assed by FICI model were interpreted as indifference in ΔE model (tab. II and III).

*n, number of combinations (amongst the 70 combinations for each strain) with statistically significant synergism ∑SYN or antagonism ∑ANT

**The increased killing colony counts of the combination between antibiotic and prenylated flavone compared to the most active single agent expressed in $\log_{10}$ CFU/mL at 24h of incubation (mean ± standard deviation)

The time-kill assay confirmed only the synergisms between MO or KG and CIP against *S. aureus* ATCC 33591 (tab. II and III; fig. 3a and 3b). The other combinations, found to be synergistic in the checkerboard method, showed additive or indifferent kinetics in the time-kill assay.

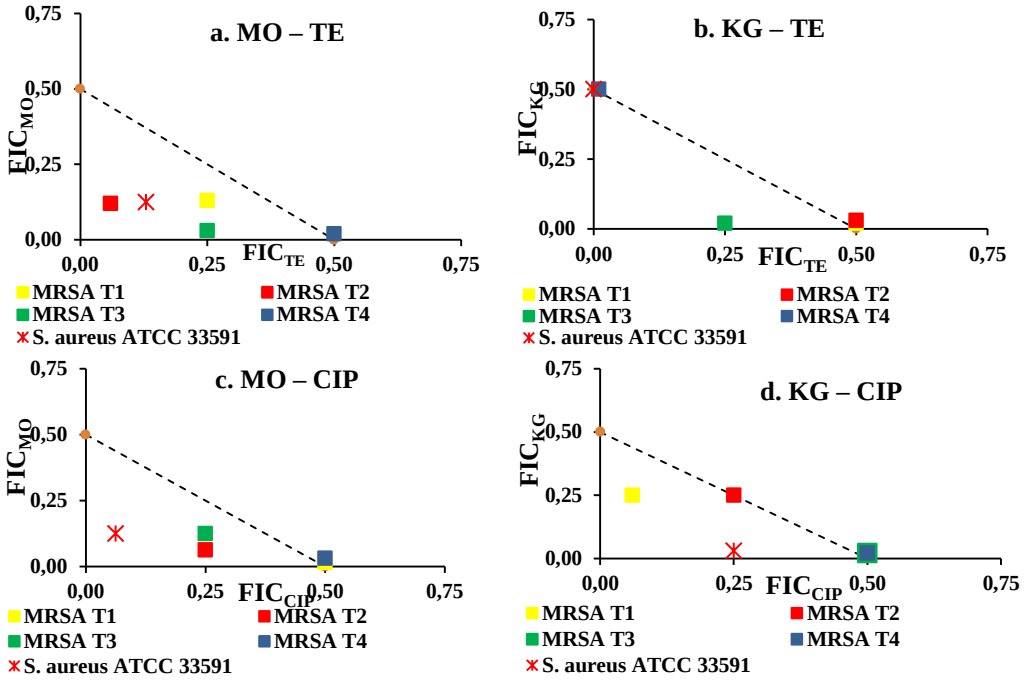

Fig. 2. Isobolograms depicting the interactions between MO or KG and antibiotics

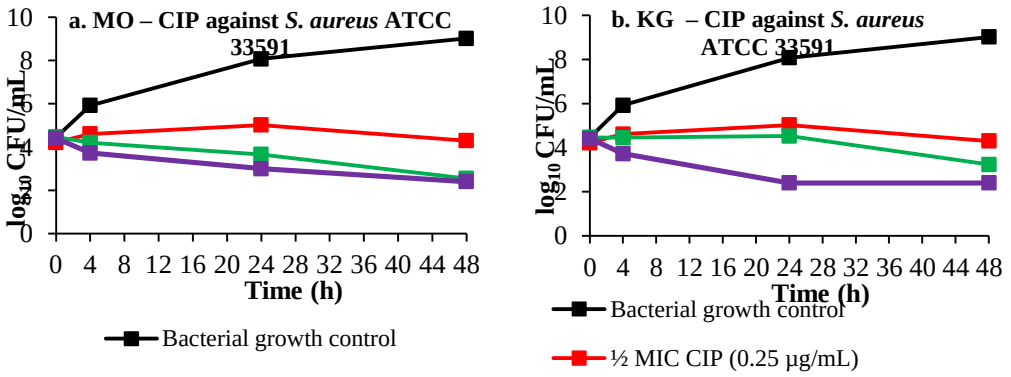

Fig. 3. Time-kill curves of MO or KG and CIP alone and in combination against *S. aureus* ATCC 33591

The interactions between prenylated flavones and antibiotics have been rarely mentioned in literature. Zuo *et al*. (2018) have recently found that four prenylflavonoids isolated form ethanolic mulberry root bark (cyclocommunol, morusinol, morusin and kuwanon E) reversed MRSA resistance to aminoglycosides, especially to amikacin (25). We have previously reported synergism between

MO or KG and other antibiotics (oxacillin, amoxicillin, erythromycin, gentamicin) against the same MRSA isolates collected from infections in dogs (MRSA T1-T4) (23, 24).

CONCLUSIONS

The combination of MO or KG with antibiotics is a promising strategy for the development of novel treatments for MRSA infections in both animals and humans.

12-YEAR FOLLOW-UP STUDY ON LONG-TERM EFFECT OF OUTDOOR AIR POLLUTION ON MORTALITY AND MORBIDITY IN FRANCE

It has been shown that air pollution has a short and long-term impact on human's health. Air pollution is a major risk factor for respiratory and cardiovascular morbidity and mortality. The impact on the respiratory system: exacerbations in chronic respiratory diseases like bronchitis, COPD, asthma, and reduced lung function due to exposure to various ambient air pollutants. This study evaluated the long-term association of the major air pollutants (PM10, PM2.5, NO2, O3) with morbidity and mortality in metropolitan France, based on preexisting data. The results show that cardiovascular and respiratory morbidity were related to NO2, along with PM2.5 and PM10. Also, exposure to NO2 and O3 could also lead to increased health risks (Shreosi Sanyal, Thierry Rochereau , Cara Nichole Maesano, *et al*. Long-Term Effect of Outdoor Air Pollution on Mortality and Morbidity: A 12-Year Follow-Up Study for Metropolitan France. http://dx.doi.org/10.3390/ijerph15110000).

CORELATIONS BETWEEN THE ENT MODIFICATIONS AND BMI IN PATIENTS WITH SLEEP BREATHING DISORDERS (Abstract): **Aim**: To show if between the BMI index of weight and the oro and hypopharingeal modifications we can establish a link for the same value of the index of AHI hypoapnea. **Material and method**: At the patients with sleep breathing pathology of an obstructive type we conducted nasal, oro- and hypopharingeal endoscopic examinations, measurements and calculation of the weight index, followed by the polygraphic evaluation of the sleep, the establishment of the degree of sleep obstructive apnea; we used a form of ENT examination. The classification of patients according to the value of the apnea index of AHI hypoapnea in 3 groups: AHI < 10, 10 < AHI < 50, and AHI > 50. According to the value of the BMI weight index we analyze 3 groups of patients : BMI < 27, 27 < BMI < 40, BMI > 40. **Results**: For AHI < 10, habitual snoring we can notice that normal amygdales appear in an increased percent for BMI < 27 or BMI > 40 and AHI < 10 the increased webbing is specific for 27 < BMI < 40. For AHI > 50 the occurring oropharingeal modifications are: normal amygdales, long and broad uvula and webbing spanning between 5-10 mm. **Conclusion**: Oropharingeal modifications and the index of BMI weight are essential elements, taken individually in the preoperatory evaluation of patients with syndrome of obstructive sleep apnea. **Key words**: OBSTRUCTIVE SLEEP APNEA, BMI INDEX, AHI INDEX

The partial or total obstruction of the upper breathing system during sleep determines the apparition of the syndrom of obstructive sleep apnea. The reduction of muscular tonus represents an important factor in the apparition of this pathology (1).

The oro and hypopharingeal structural modifications are essential elements in explaining the etiology of the syndrome of obstructive sleep apnea. To this we can add the influence played by the neck's greasy tissue in the link of the upper breathing ways following the external compression of this upon the pharyngeal walls (2,3,4). Obesity represents an important factor in the apparition of the obstruction of upper breathing ways during sleep, hypoventilation and desaturation, as well as in the apparition of arterial hypertension in patients with the syndrome of sleep apnea.

It is known that both BMI index as well as oropharingeal modifications represent

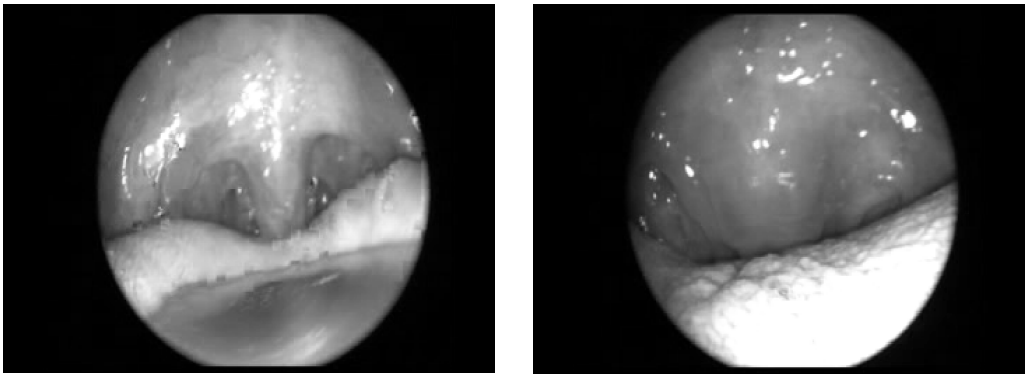

Fig. 1. Endoscopic aspect of the oropharingeal modifications

Fig. 2. Polygraphic recording

individually determining factors of the syndrome of sleep apnea (5,6,7,8). What is not known is whether between the two parametres for the same value of the apnea index there is or is not a link worth taking into consideration.

The aim of this study was to show if between the BMI index of weight and the oro and hypopharingeal modifications we can establish a link for the same value of the index of AHI hypopneous apnea, or if the two parametres have an importance only individually and a significant relationship cannot be established between them.

MATERIAL AND METHOD

The realisation of this study had at its base the examination of some patients with sleep breathing pathology of an obstructive type. In these patients we conducted nasal, oro and hypopharingeal endoscopic examinations, measurements and calculation of the weight index, followed by the polygraphic evaluation of the sleep and the establishment of the degree of sleep obstructive apnea. In view of the evaluation of oro and hipopharingeal modifications, we used a form of ENT examination. Through the filling of this examination questionnaire, in view of the study we selected patients according to the growth of the amygdales, this way : normal ones, hypertrophied ones and massively hypertrophied ones, according to the growth of the uvula – long and broad uvula, as well as according to the value of the webbing : webbing between 5-10 mm and webbing greater than than 10 mm (fig. 1).

The polygraphic recording done allowed the classification of patients according to the value of the apnea index of AHI hipoapnoea in 3 groups : $AHI < 10$, $10 < AHI < 50$, and $AHI > 50$ (fig. 2).

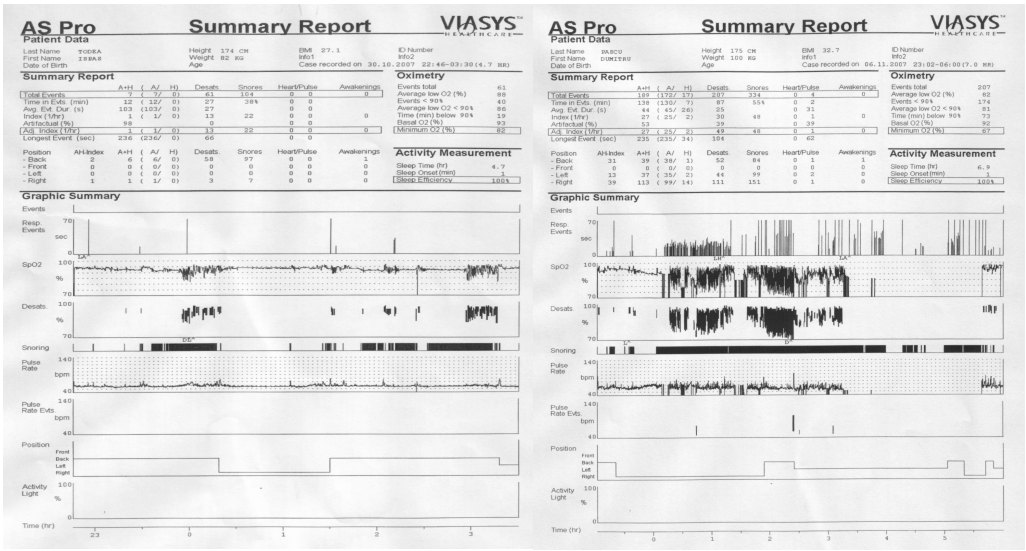

Fig. 3. Polygraphic result of the evaluation of the BMI index

The classification of the patients was also done according to the value of the BMI weight index in 3 groups: BMI < 27, 27 < BMI < 40, and BMI > 40 (fig. 3).

For the same value of the AHI index the values of the BMI weight index were correlated with the frequency in percents of the growth of amygdales, uvula and the webbing index.

RESULTS AND DISCUSSIONS

For AHI < 10, habitual snoring (fig. 4) we can notice that normal amygdales appear in an increased percent only for BMI < 27 or BMI > 40.

The long and broad uvula is specific for BMI < 27 and in a smaller percentage for 27 < BMI < 40.

For 10 < AHI < 50 (fig. 5) equivalent to the syndrome of incipient and moderate obstructive apnea we can conclude the following: normal amygdales as growth appear both for patients with BMI < 27 as well as for patients with BMI > 40, amygdaline hypertrophy being more frequent in patients with 27 < BMI < 40.

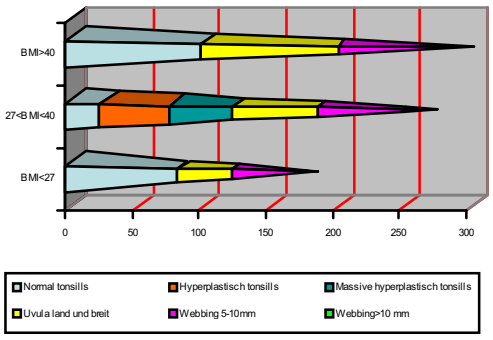

Fig. 4. The correlation between the oropharingeal modifications and the BMI index for value AHI < 10

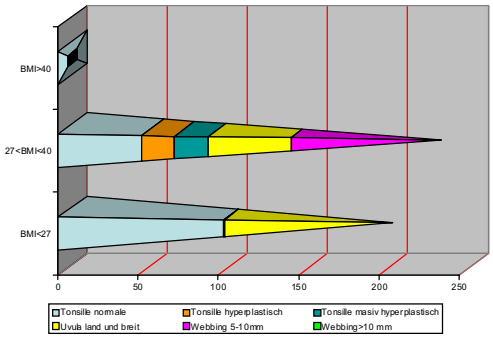

Fig. 5. The correlation between oropharingeal modifications and the BMI index for value 10 < AHI < 50

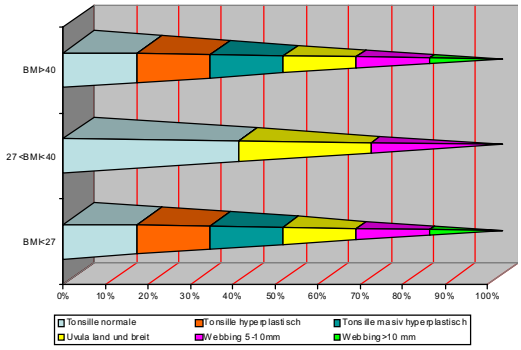

Fig. 6. The correlation between the oropharingeal modifications and the BMI index for value AHI > 50

The long and broad luette appears more frequently in patients with BMI : 40, the webbing between 5-10 mm occurring in a comparatively equal percentage with BMI and more increased at BMI > 40, while the webbing > 10 mm is specific for 27 < BMI < 40.

In such situations for AHI < 50 corresponding to a syndrome of severe obstructive apnea making a comparative analysis of the results we can say that between the growth of the amygdales and the value of the BMI index there is not a direct link, while the webbing spanning from 5-10 mm increases proportionally with the frequency with BMI.

For AHI > 50 (fig. 6) the occurring oropharingeal modifications are : normal amygdales, long and broad uvula and webbing spanning between 5-10 mm. Their values are significant only for 27 < BMI < 40.

CONCLUSIONS

Oropharingeal modifications and the index of BMI weight are essential elements, taken individually in the preoperatory evaluation of patients with syndrome of obstructive sleep apnea.

For the same value of the AHI index of apnoea-hipopnoea thus for the same pathological clinical status there are great variations between the oropharingeal modifications and the BMI weight index without being able to say that in patients with snoring and syndrom of severe obstructive apnea once with the growth of BMI index the oropharingeal parametres are modified proportionally, increasing in frequency. For the syndrome of incipient and moderate obstructive apnea these modifications pass through a quite constant modification which is essential in the preoperatory evaluation of this category of patients.

A COMPARAISON BETWEEN THE TOTAL PSA, THE GLEASON SCORE AND THE BONE SCINTISCAN RESULTS FOR DIFFERENT AGE GROUPS (Abstract): The aim of the study is to compare de results of the bone scintigraphy of prostate cancer patients in different age groups with their total PSA (PSAt) and with their histopathological test results. **Materials and metods**: Of the 180 patients with prostate cancer who were analyzed by Scintiscan in the last five years in our laboratory, 86 have a known PSAt value, and of these, 55 have a known Gleason Score. The 180 patients were divided into three age groups: 1) < or equal 60 years; 2) 60-70 years and 3) >70 years. The 86 patients with a known PSAt were also divided into five groups according to their PSAt value and the 55 patients with a known Gleason Score were divided in three groups. The scintigraphy results included all the patients in 3 groups, according to the presence, the absence or the likelihood of having bone metastasis. The 33 patients with proven bone metastasis were divided, according to their numbers, into the four Soloway groups. **Results**: Among the patients with PSAt > 20 ng/mL, considered high risk for bone metastases, according to the Recomandations of CCAF, 21 (32.81%) of the 64 patients do not show the presence of bone metastases. For PSAt > 50 ng/mL, all 5 patients < 60 years of age have metastases, while only 15 (62.5%) of the 24 patients over 70 years old have metastases and 1 (4%) has low likelihood. 6 (21.42 %) of the 28 patients with PSAt > sau egal 100 ng/mL do not have metastases. 10 (43.4 %) of the 23 patients with a Gleason Score <7, considered low risk, do have metastases (6 patients – 26%) or low probability of metastases (4 patients – 17.4%). **Conclusions**: Our study confirms that the probability of bone metastasis for a high PSAt value is reversely proportional to age. In our study there is no direct correlation between Gleason Score and the bone scan results.

KEY FACTORS FOR MINI-IMPLANT SUCCESS: THE CRITICAL ROLE OF CORTICAL BONE THICKNESS AND ORTHODONTIC FORCES IN ENHANCING STABILITY AND PREVENTING FAILURE (Abstract): This study **aims** to analyze the biomechanical performance of titanium (Ti6Al4V) mini-implants (MIs) under orthodontic forces using finite element analysis (FEA) and to evaluate stress, strain, and displacement behavior within cortical and spongy bone under realistic clinical conditions. **Materials and methods:** A three-dimensional finite element model of a mini-implant (2.0 mm diameter, 12 mm length) was developed using CT-based reconstruction of the mandible and periodontal ligament. The model was meshed with tetrahedral elements and simulated in ANSYS Workbench 19.2. Material properties for bones, teeth, ligament, and implant were defined as linear elastic, homogeneous, and isotropic. Orthodontic forces of 2N and 10N were applied at a 30° angle to replicate molar intrusion scenarios. Stress, strain, and displacement distributions were analyzed for cortical and spongy bone, with special attention to localized areas of maximum impact. **Results:** Maximum von Mises stress and equivalent strain values were localized around the implant insertion site. Cortical and spongy bone demonstrated high resistance to applied forces, with stress and strain levels remaining below their fracture thresholds. The results highlighted the critical role of cortical bone thickness in ensuring primary stability. Displacement was minimal, with a maximum value of 0.028948 mm at the implant head under a 2N force, demonstrating functional stability. Forces exceeding 3N were identified as the threshold for potential spongy bone failure, reinforcing the appropriateness of 2N for orthodontic applications. **Conclusions:** The study confirms that mini-implants can effectively withstand orthodontic forces when inserted into adequate cortical bone thickness. The integration of finite element modeling with clinical insights provides valuable guidance for optimizing mini-implant performance and minimizing adverse effects. These findings contribute to improving treatment strategies and ensuring the longevity of orthodontic anchorage systems. **Keywords:** FINITE ELEMENT METHOD (FEM); FRACTURE; MINI-IMPLANT; ORTHODONTIC FORCES; STRESS DISTRIBUTION; BONE-IMPLANT INTERACTION.

INTRODUCTION

Cortical bone serves as a structural barrier during orthodontic tooth movement, and its thickness can significantly affect the mechanical stress experienced by the bone when orthodontic forces are applied. For

instance, studies have shown that the stress in cortical bone can increase dramatically in response to orthodontic forces, potentially leading to microfractures and bone loss, especially in areas where the bone is already thin (1). The remodeling of alveolar bone around moving teeth is a well-documented phenomenon in orthodontics, yet the specific impact of cortical bone thickness on this process remains underexplored (1). Understanding this relationship is essential, as inadequate bone support can lead to mini-implant failure, which has been reported to occur in up to 28% of cases due to insufficient cortical bone quality and quantity (2). Moreover, the application of orthodontic forces must be carefully calibrated to avoid overloading the cortical bone, which can result in adverse outcomes such as periodontal tissue loss and compromised tooth stability (3, 4). The interaction between orthodontic forces and cortical bone thickness is particularly relevant when considering the use of temporary anchorage de-vices (TADs), where the primary stability of mini-implants is heavily influenced by the surrounding bone characteristics (5, 6). Research indicates that the quality and thickness of cortical bone at the insertion site are critical determinants of the success of these devices (7, 8).

The simultaneous study of cortical bone thickness and orthodontic forces is critical for advancing orthodontic practices and improving patient outcomes. A significant gap in current orthodontic research lies in the understanding of how variations in cortical bone thickness influence the response to orthodontic forces, particularly in the context of mini-implants used for anchorage.

Moreover, patient-related factors such as age, oral hygiene, and systemic health conditions can significantly influence the success rates of mini-implants (9). The impact of mechanical factors on bone stress and strain in orthodontic mini-implants is a critical area of study that integrates biomechanics, material science, and biological responses. Experimental research in orthodontics today aims to investigate the usefulness of recent technology and advancements into predictable methodology by incorporating tools such as finite element analysis (FEA), 3D CAD CAM, low-level laser therapy (LLLT) and digital simulations (10-12). These technologies enable more accurate predictions of treatment outcomes, better understanding of biomechanical forces, and the development of customized, patient-specific approaches.

Through these advancements, researchers can refine diagnostic techniques and optimize the performance of orthodontic appliances, making treatments more efficient, reliable, and less invasive. Research has shown that the insertion angle of mini-implants plays a crucial role in stress distribution within the bone. For instance, Popa *et al.* (13) demonstrated that increasing the insertion angle from 30° to 120° results in decreased stress on the bone, indicating that a more oblique insertion can lead to better stress distribution and potentially lower the risk of implant failure. An increase in insertion angle can influence stress levels, the torque required for removal does not consistently correlate with stress distribution across all angles, suggesting a more complex interaction (14). The mechanical properties of the materials used for mini-implants also significantly affect their performance. The use of titanium alloys, particularly Ti6Al4V, is prevalent due to their favorable mechanical properties and biocompatibility, which are essential for maintaining stability during orthodontic treatment (15).

However, discrepancies in Young's

modulus between the implant material and the surrounding bone can lead to stress-shielding effects, potentially resulting in implant loosening over time (15). This highlights the importance of selecting materials that closely match the mechanical properties of bone to optimize the performance of mini-implants. Furthermore, the dimensions of mini-implants, including their diameter and length, have been shown to influence their mechanical stability. Kovuru's finite element study indicated that larger diameter and longer mini-implants resulted in decreased mobility, which correlates with reduced stress on the adjacent bone (2). This finding is consistent with other studies that emphasize the importance of implant design in minimizing stress concentrations in the peri-implant bone (16, 17). The biological response of the periodontal ligament (PDL) to mechanical forces is also a critical factor in understanding bone remodeling around mini-implants. Mechanical stress applied during orthodontic treatment induces various cellular responses in the PDL, which are essential for bone remodeling. For example, moderate mechanical loading has been shown to promote osteogenesis, while excessive forces can lead to cellular damage and dysregulation of bone remodeling processes (18, 19). The balance of mechanical forces is vital; while moderate stress supports bone formation, excessive stress can trigger bone resorption and negatively impact the stability of mini-implants (20, 21). The Finite Element Method (FEM) has emerged as a pivotal tool in the biomedical field, especially in orthodontics and the design of medical implants such as hip prostheses, surgical instruments, and external fixators, offering the advantage of simulating complex biological systems and enabling detailed analysis of stress and strain distributions in tissues like the periodontal ligament (PDL), alveolar bone, and surrounding structures, as well as predicting the mechanical behavior of medical devices under various loading conditions to enhance their design and functionality . (22-24). An increase in cortical bone thickness is hypothesized to significantly improve the primary stability of mini-implants in ortho-dontic treatments, reducing the likelihood of implant failure under standard orthodontic forces. Conversely, thinner cortical bone is expected to result in higher stress concentrations, which may decrease implant longevity and increase the likelihood of failure when subjected to higher orthodontic forces. Optimal loading conditions are hypothesized to increase the mechanical stability of orthodontic mini-implants by reducing stress, strain, and displacement in both the implant and surrounding bone, thereby enhancing long-term success in orthodontic applications.

MATERIALS AND METHODS

In this study, a titanium (Ti6Al4V) mini-implant, with dimensions of 2.0 mm in diameter and 12 mm in length, was modeled using the finite element method (FEM) (Figure 1). The mandible's geometry was derived from scanned data, with computed tomography (CT) images being processed and digitized (Figure 1). Three-dimensional solid models of both the mini-implants and the mandible were created and integrated using SpaceClaim, a commercial computer-aided design (CAD) software (Figure 1). The periodontal ligament was represented with a 0.25 mm thickness, corresponding to the outer geometry of the dental roots. The mini-implant's insertion point was positioned midway along the depth of the roots of both premolars, specifically in the space between the premolar and molar. The entire

model was imported into the finite element analysis software (version 2021; ANSYS, Inc., Canonsburg, Pennsylvania, USA) and discretized using automatically generated 10-node tetrahedral structural elements (fig. 4). The materials for the bones, teeth, periodontal ligament, and mini-implant were modeled as linear elastic, homogeneous, and isotropic, with mechanical properties sourced from published literature. To ensure convergence in the finite element model, various element sizes, ranging from 0.3 mm to 1.2 mm, were tested. It was concluded that an element size of 0.3 mm was optimal for the mini-implant insertion area, while 0.8 mm was suitable for the rest of the model.

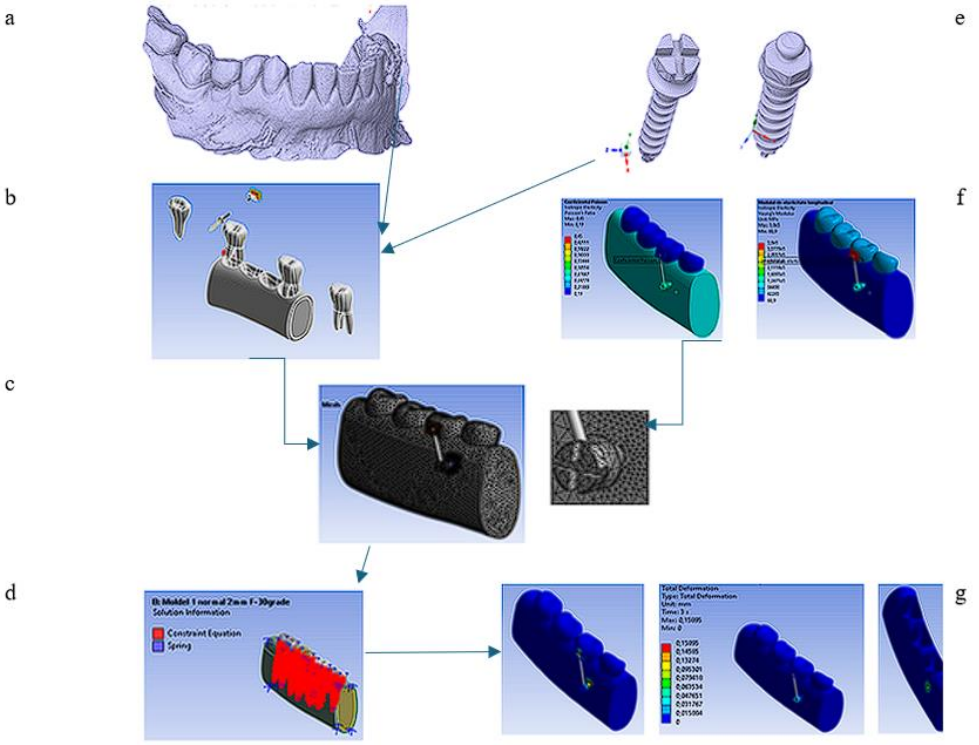

Fig. 1. Digital workflow for structural analysis of mini-implants using CT data: a. Mandible STL file; b. Geometric model (CAD): Teeth, PDL, Adhesive, Mini-implant, Mandible (cortical bone and spongy bone), Bracket; c. Discretized model; d. Analysis settings; e. Mini-implant STL file; f. Material model; g. Obtained results.

The interfaces between the teeth and the periodontal ligament were assumed to be bonded, while a frictional contact (friction coefficient = 0) was assumed between the bone and the mini-implant. Orthodontic forces ranging from 0.1 N to 10 N were applied. A force of 2 N and an additional 10 N force were applied at a 30° angle relative to the vertical axis (Y) to simulate real-world orthodontic conditions. These forces were directed from the mini-implant toward the molar via the connector tube, accurately representing the biomechanics involved in a molar intrusion scenario with

skeletal anchorage. This angled application reflects clinical load transfer during orthodontic treatments and allows for a realistic assessment of stress and strain distributions within the periodontal ligament, alveolar bone, and surrounding tissues.

The inclined force direction plays a crucial role in controlling the intrusion of the first molar, making this model a precise simulation for evaluating biomechanical responses during this specific orthodontic movement. These models were created using SpaceClaim software, (19.2, ANSYS, Inc., Canonsburg, Pennsylvania, U.S) which allowed for the import and remodeling of CT images in STL format. The models were geometrically simplified to ensure stability during finite element analysis without compromising realism (fig. 1). Finite element modeling involved discretizing the 3D models into a large number of elements and nodes (fig. 1). The mesh was finer in critical areas, such as the insertion site of the implant and the adjacent region. The CAD model was automatically meshed into finite elements using ANSYS Workbench 19.2 software (ANSYS Workbench 19.2, Canonsburg, Pennsylvania, U.S). Material properties, such as Young's modulus and Poisson's ratio, were specified for each component of the implant system (fig. 1). Contact conditions were also defined to simulate interactions between the different parts of the model.

RESULTS

Results obtained for the loading scenario with 2N, 30° to the normal

Figure 2 provides a visual representation of the results from the finite element analysis for the loading scenario where a 2N force is applied at a 30° angle to the normal. This analysis is crucially important in understanding the stress, strain, and displacement behavior of the bone-implant system under orthodontic loading conditions.

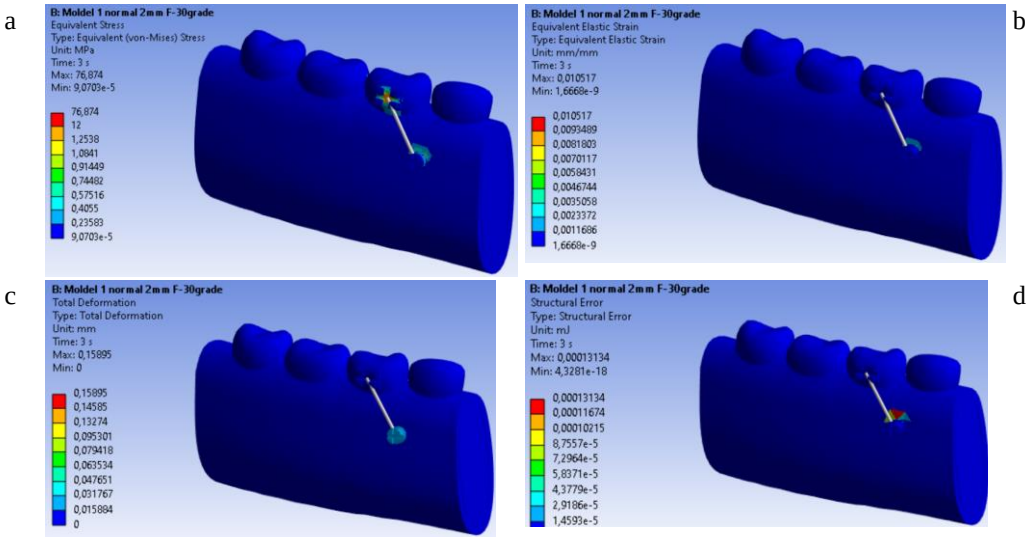

Fig. 2. The von Mises equivalent stress state, strain state, total displacements, and structural error on the global model: a. The von Mises equivalent stress state on the global model; b. The equivalent strain states on the global model; c. Total displacements on the global model; d**.** Structural error on the global model.

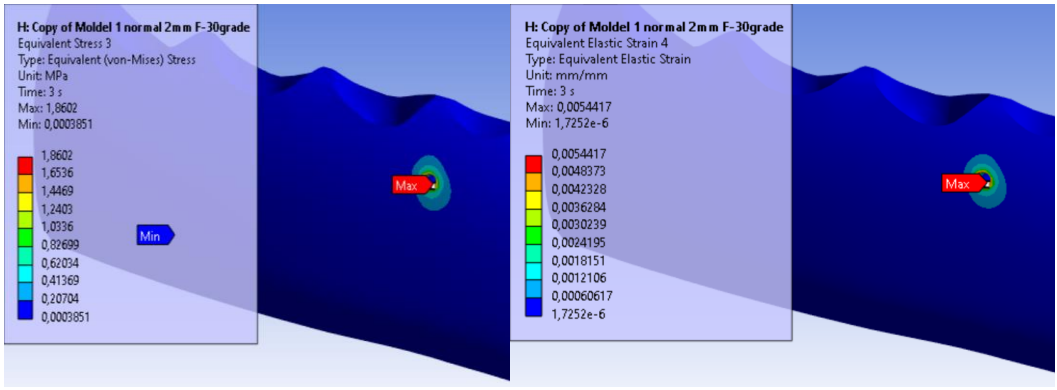
Figure 2 (a) displays the von Mises equivalent stress state on the global model. This indicates the distribution of stress throughout the model. Areas with higher stress concentrations can be observed, which are essential in predicting potential failure points or areas of concern regarding structural integrity. Figure 2 (b) shows the equivalent elastic strain state on the global model. This provides insights into how the material deforms under load, with higher strain regions indicating areas where the material undergoes significant deformation. Figure 2 (c) represents the total displacements on the global model. This gives an overall picture of how much the mini-implant and surrounding structures move or displace in response to the applied force, crucial for assessing the functional stability of the mini-implant in a clinical setting. Figure 2 (d) highlights the structural error on the global model. Structural error maps are essential for verifying the reliability of the simulation, ensuring that the model's results fall within acceptable error margins and the analysis is valid.

Results obtained in cortical bone

In Figure 3a, the von Mises equivalent stress state on the cortical bone is presented. The maximum value obtained is 5.29 MPa in the area immediately surrounding the orthodontic anchorage. It can be observed that relatively high values are obtained in a relatively small volume of material, with the area indicated as "Max" in the image. The stress values are five times lower or more for the areas adjacent to the recorded maximum.

Based on the results obtained for the compressive strength of the cortical bone (200 MPa) and the tensile strength (110 MPa), it can be concluded that the bone is not affected by the orthodontic anchorage. The value obtained is much lower than the fracture limit of the cortical bone.



a b

Fig. 3. Results obtained in the cortical bone in the mini-implant insertion area: a. The von Mises equivalent stress state in the cortical bone in the mini-implant insertion area; b. The equivalent strain state in the cortical bone in the mini-implant insertion area.

In Figure 3b, the equivalent linear strain state on the cortical bone is presented. The maximum value obtained is 0.016378 mm/mm in the area immediately surrounding the orthodontic anchorage, at the node with the maximum von Mises stress value.

Relatively high values are observed in a relatively small volume of material, with the area indicated as “Max” in the image.

Based on the results obtained for the cortical bone’s resistance to compression (0.0085 mm/mm) and to tension (0.007 mm/mm), it can be concluded that the bone is affected by the orthodontic anchorage only at the node where the maximum value was recorded. The value obtained for the rest of the material in the area immediately surrounding the anchorage is lower than the specific linear deformations obtained experimentally for cortical bone.

In Figure 4, the graph of maximum von Mises equivalent stresses as a function of loading force in the cortical bone section is presented. The maximum value obtained is 17.972 MPa in the most stressed area, which is the same area shown in Figure 3a for a force magnitude of 10N, while the value door 2N orthodontic force is 5.2914 MPa. The nonlinear graph is a result of the application of nonlinear contact between the mini-implant and the cortical bone. The graph shows that the fracture limit values of the cortical bone are not exceeded for all applied force values, indicating that the cortical bone withstands forces greater than 10N

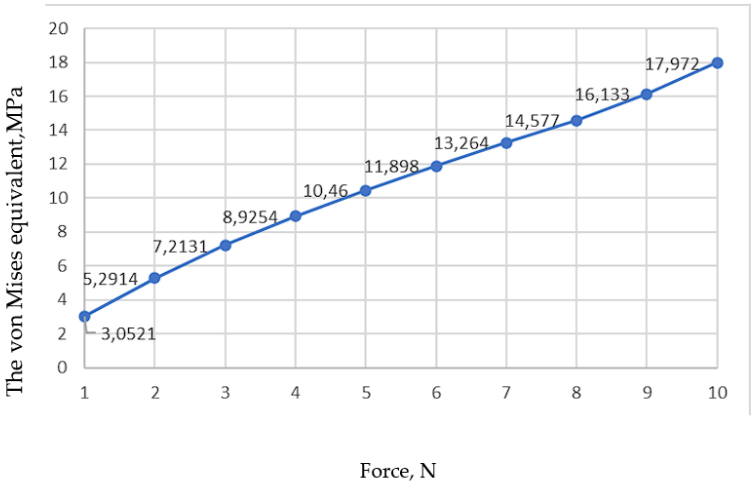


Fig. 4. The von Mises equivalent stress state in the cortical bone.

Results obtained in the spongy bone

In Figure 5a, the von Mises equivalent stress state in the spongy bone is presented. The maximum value obtained is 1.86 MPa in the area immediately surrounding the orthodontic anchorage. It can be observed that relatively high values are concentrated in a relatively small volume of material, with the area indicated as "Max" in the image. The stress values are five times lower or more for the areas adjacent to the recorded maximum. Based on the results obtained for the compressive strength of the spongy bone (2.6 MPa) and the tensile strength (2.3 MPa), it can be concluded that the bone is not affected by the orthodontic anchorage. The value obtained is much lower than the fracture limit of the spongy bone. In Figure 5b, the equivalent linear strain state in the spongy bone is presented. The maximum

value obtained is 0.0054417 mm/mm in the area immediately surrounding the orthodontic anchorage, at the node with the maximum von Mises stress value. Relatively high values are observed in a relatively small volume of material, with the area indicated as "Max" in the image. Based on the results obtained for the compressive strain resistance of the spongy bone (0.08 mm/mm) and tensile strain resistance (0.13 mm/mm), it can be concluded that the bone is affected by the orthodontic anchorage only at the node where the maximum value was recorded. The value obtained in the rest of the material in the area immediately surrounding the anchorage is lower than the specific linear deformations obtained experimentally for spongy bone.

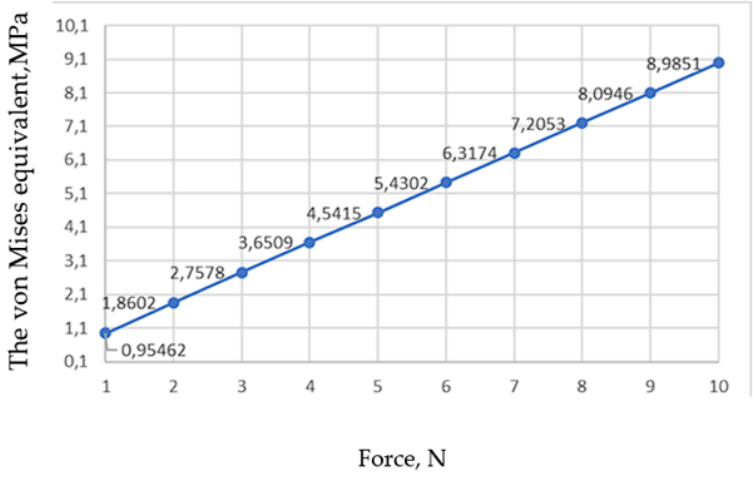

Fig. 6. The von Mises equivalent stress state in the cortical bone.

In Figure 6, the graph of maximum von Mises equivalent stresses as a function of loading force in the spongy bone section is presented. The maximum value obtained is 8.98 MPa in the most stressed area, which is the same area shown in Figure 14 a for a force magnitude of 10N, while the minimum value is 1.8602 MPa for an orthodontic force of 2N. The graph indicates that the fracture limit values of the spongy bone are exceeded for applied forces greater than 3N, suggesting that the spongy bone withstands forces up to 3N. If this force is exceeded, there is a likelihood of cracks forming. It is also observed that a force of up to 2N, chosen for orthodontic treatment, is appropriate, as this value is supported by most studies.

TABLE I.
Results for cortical and spongy bone.

Parameter	Result	Threshold/Limit
Maximum Von Mises Stress	5.29 MPa near anchorage	Compressive: 200 MPa, Tensile: 110 MPa
Maximum Equivalent Linear Strain	0.016378 mm/mm near anchorage	Compression Resistance: 0.0085 mm/mm, Tension Resistance: 0.007 mm/mm
Maximum Von Mises Stress	1.86 MPa near anchorage	Compressive: 2.6 MPa, Tensile: 2.3 MPa

The results suggest that both cortical and spongy bone (tab. I) largely remain within the safe limits of their mechanical strength. However, the slight deformation exceeding the permissible limit in the cortical bone at maximum stress may indicate a vulnerable area, especially under repetitive loading scenarios.

DISCUSSION

FEA is a powerful computational tool used to predict the mechanical behavior of structures under various loading conditions. However, the accuracy of FEA results is highly dependent on the assumptions made during modeling. The presumption of 100% osseointegration simplifies the model but neglects the variability inherent in biological systems. This can lead to erroneous predictions regarding stress distribution, load transfer, and potential failure modes of implants (25).

Impact of von Mises equivalent stress on cortical bone: The maximum values of von Mises equivalent stress are recorded in the area immediately surrounding the orthodontic anchorage. These high values indicate a concentration of stresses in this region, which may be associated with the risk of deformation or bone damage. However, it is important to note that the relative stress values are lower in the areas adjacent to the recorded maximum, suggesting that the orthodontic impact on the cortical bone is localized and does not significantly affect the entire bone. Equivalent linear strain in cortical bone: The maximum values of equivalent linear strain are also recorded in the area immediately surrounding the orthodontic anchorage.

These strains may indicate excessive loading or a weakness in the bone in this region. However, similar to von Mises stress, the strains are localized and do not significantly affect the entire cortical bone. Cortical bone resistance to compression and tension: By comparing the cortical bone's resistance to compression and tension with the deformations and stresses induced by the orthodontic anchorage, it can be observed that the bone is not significantly affected. The resistance values of the cortical bone are much higher than the deformations and stresses induced by the orthodontic anchorage, indicating the bone's ability to withstand the applied

orthodontic forces. Importance of the localization of maximum stress and strain: The fact that maximum stress and strain are localized in a small area of the cortical bone suggests that orthodontic treatment has a concentrated impact, which can be effectively managed and monitored. This aspect can be considered in developing and implementing orthodontic treatment strategies that minimize adverse effects on the cortical bone.

Impact of von Mises equivalent stresses on spongy bone: The maximum values of von Mises equivalent stresses are recorded in the area immediately surrounding the orthodontic anchorage on the spongy bone. These high values indicate a concentration of stresses in this region, which may be associated with the risk of deformation or bone damage. However, the relative stress values are lower in the areas adjacent to the recorded maximum, suggesting that the orthodontic impact on the spongy bone is localized and does not significantly affect the entire bone. Equivalent linear strain in spongy bone: The maximum values of equivalent linear strain are also recorded in the area immediately surrounding the orthodontic anchorage on the spongy bone. These strains may indicate excessive loading or a weakness in the bone in this region. However, similar to von Mises stresses, the strains are localized and do not significantly affect the entire spongy bone. Spongy bone resistance to compression and tension: By comparing the spongy bone's resistance to compression and tension with the deformations and stresses induced by the orthodontic anchorage, it can be observed that the bone is not significantly affected. The resistance values of the spongy bone are much higher than the deformations and stresses induced by the orthodontic anchorage, indicating the bone's ability to withstand the applied orthodontic forces. Importance of contact pressure distribution: The distribution of contact pressure between the mini-implant and the spongy bone can influence the stability and durability of the orthodontic anchorage. The maximum contact pressure highlights areas of maximum load and can provide information on the potential for bone damage or weakening in the anchorage area. Evaluation of stress and strain in cross-section: The analysis of stresses and strains in the anchorage section provides detailed information on the structural behavior of the bone in the mini-implant insertion area. The maximum values of stress and strain are localized in the areas adjacent to the mini-implant and can be considered in the design and adjustment of orthodontic treatments to minimize adverse effects on the bone.

The maximum displacement value of 0.028948 mm is observed at the head of the mini-implant, in the area where the orthodontic force is applied. This information is useful for evaluating the structural behavior of the orthodontic anchorage system and identifying areas of greatest mobility during treatment. Von Mises equivalent stress in cross-section: This analysis is important for evaluating the mechanical stress to which the orthodontic anchorage system is subjected and for identifying critical areas concerning material resistance and deformation. To accurately model the interactions between mini-implants and bone tissue, several crucial factors must be considered. Research has indicated that the insertion angle of mini-implants into the bone significantly influences stress reduction and stability (5). It is recommended that mini-implants be inserted at a 30° angle to achieve optimal results. The fit of the mini-implant threads into the bone is vital for

stability and the ability to withstand applied forces (26).

Cortical bone thickness is a crucial factor in determining the primary stability of mini-implants. Thicker cortical bone has consistently been associated with increased initial stability of mini-implants, while thinner cortical bone has been linked to a higher risk of implant failure (5). Studies have highlighted the importance of cortical bone thickness in influencing primary stability, with some research emphasizing it as the most critical factor affecting the success rate of mini-implants (6). Research has shown that increasing cortical bone thickness significantly increases the pull-out force, underscoring the importance of bone quality for primary stability. Studies have indicated that mini-implants achieve greater primary stability in denser cortical bone (5, 27-31). The choice of mini-implant design and size is crucial for establishing sufficient primary stability, particularly considering the insertion region and local bone quality (30, 32).

Cortical bone thickness has been identified as a critical factor in stabilizing mini-implants, with some studies suggesting that it may be the most important factor in ensuring stability (33, 34). The influence of cortical bone thickness on primary stability has been further supported by research showing that greater cortical bone thickness increases the initial stability of the implant (35, 36). The primary stability of mini-implants is significantly affected by the quality and thickness of the cortical bone at the insertion site. Thicker cortical bone is associated with increased stability and a higher success rate for mini-implants, emphasizing the importance of considering both bone quality and quantity when planning mini-implant placement. There is a consensus in various studies that cortical bone thickness is a key determinant of the initial stability of mini-implants in orthodontics.

Thin cortical bone presents a risk of implant failure, while adequate cortical bone thickness -typically greater than 1 mm- is essential for ensuring the stability and success of orthodontic mini-implants. The mechanical properties of biological tissues, including bones and the periodontal ligament, are well-known to be viscoelastic and highly dependent on the rate of deformation. Orthodontic treatment is a progressive process that uses small-magnitude orthodontic forces, as the deformation and displacement of dental tissue require time to modulate. Based on this condition and assuming that alveolar bone is a ductile material, von Mises stress has been widely accepted in orthodontic research.

The selection of this stress index has been advantageous because it is a scale designed to quantify stress without directional orientation. This stress index makes it easier for clinicians to predict where stress concentrators may appear; this is important because higher stress levels can lead to potential mini-implant failure. The results of our study indicated that the equivalent stress and strain state in the cortical bone was primarily affected by the exposed length of the mini-implant, the type of mini-implant, and the material from which the mini-implant is made. Previous research has mainly focused on the insertion length of mini-implants. In 2011, Chatzigianni *et al.* reported that the displacement of longer mini-implants under a force of 2.5 N was greater than that of shorter implants (37). Several studies have shown that longer mini-implants have higher success rates than shorter ones. Sometimes, the head of the mini-implant may become covered by the alveolar mucosa. In such cases, intervention with ortho-

dontic devices such as elastic chains or coil springs could lead to inflammation of the alveolar tissue, which is strongly correlated with mini-implant failure. Partial insertion of longer mini-implants could minimize the possibility of the alveolar mucosa covering the head of the mini-implant, thereby reducing the chances of failure. Studies have shown that variations in cortical bone thickness can influence the stress distribution around mini-implants during orthodontic loading. For instance, Hirai *et al.* utilized 3D FEA to demonstrate that the insertion depth of miniscrews affects the stress distribution in both the screws and the surrounding bone, indicating that optimal insertion depth is crucial for minimizing stress concentrations and enhancing stability (38).

Clinical implications

These results can be discussed in the context of clinical orthodontic practice, highlighting the importance of understanding the mechanical behavior of mini-implants and identifying strategies to improve their performance during orthodontic treatment. This could include modifications to insertion techniques, improvements in mini-implant materials, or adjustments to the treatment protocol to minimize the risk of complications or failures.

Future research directions: Based on these results, future research directions could be suggested to further investigate the mechanical behavior of mini-implants and develop new strategies or technologies to improve their stability and performance in clinical practice. This could include additional computer simulation studies or experimental tests to validate and expand upon the current findings.

Reasons for the selection of 12 mm length in mini-implants. The decision to utilize a 12 mm length for the mini-implants (MIs) was made based on several key considerations: *(i)Enhanced stability*: longer mini-implants have the potential to offer superior primary stability, particularly in cases where bone density is lower (32); *(ii)Improved bone anchorage*: in certain clinical scenarios, the thickness of both the cortical and spongy bone layers may necessitate the use of longer mini-implants to achieve adequate depth of anchorage (12)*; (iii) Supporting literature*: while the minimum recommended length for mini-implants is typically around 6 mm, existing studies indicate that longer implants can lead to improved long-term performance, particularly in regions with varying bone density (1). The selection of the 12 mm length was informed by both theoretical evidence and practical applications observed in prior research. *(iv) Clinical experience*: our clinical experience further supports the use of 12 mm mini-implants, as they have consistently demonstrated favorable outcomes in terms of stability and osseointegration, particularly in more complex cases where additional length may provide a critical advantage.

CONCLUSIONS

The findings demonstrated that von Mises stress and equivalent strain were localized around the mini-implant anchorage, without significantly affecting the surrounding bone structure. Both cortical and spongy bone showed resistance levels far exceeding the applied forces, confirming their capacity to withstand orthodontic loading. However, areas of maximum stress and strain require careful consideration to avoid localized damage or potential failure. Additionally, the role of cortical bone thickness as a key determinant of primary stability was reinforced, with thicker bone consistently linked to better outcomes. this

study underscores the value of understanding the mechanical behavior of mini-implants to ensure their effective use in orthodontic practice. By integrating FEA insights with clinical observations, orthodontic treatments can be tailored to maximize outcomes while minimizing complications, paving the way for more predictable and reliable MI applications.

CONFLICT OF INTEREST AND FUNDING

The authors declare no conflicts of interests.

The research did not receive external funding.

NOISE POLLUTION IN REHABILITATION SETTINGS (Abstract): Noise pollution is one of the main pollutants in the urban areas and a major challenge for rehabilitation units. Noise affects both patients during the healing process and doctors during healthcare activities. Noise comes from the exterior and the interior of the medical ward. Due to the use of powered instruments, orthopedic surgery is the loudest medical setting (between 66 and 100 dB A). Intensive care units may reach sound levels between 55 and 70 dB A. Neurosurgery, urology, cardiology and gastrointestinal surgery produce between 62 and 65 dB A. WHO has provided guidelines for specific noise levels within hospital units, recommending noise levels not exceeding 30 dB A at night and 35 dB A during the day. One of the main sources of noise in hospital activity is represented by the conversations undertaken by medical professionals, doctors and patients, patients and visitors. However, medical rehabilitation is an area in which such discussions are more necessary, as long-term therapies require active involvement of the patient and family members or caregivers. Besides family and patient, the rehabilitation process requires a well-connected multidisciplinary team made of doctors, nurses, psychologists, physical therapists, occupational therapists, speech and respiratory therapists, dietitians and social workers, who share medical information almost entirely verbally. That is why, rehabilitation doctors and nurses should be aware of the need to maintain a muffled voice tone. Minimizing the sound levels of all technological devices used in the rehabilitation units should be also considered. When possible, the design of new rehabilitation units must aim not only at earthquake safety, functionality and cleanliness, but also at the reduction of hospital noise. **Keywords**: NOISE POLLUTION, PREVENTION, REHABILITATION, SOUND LEVELS.

As patients in medical rehabilitation are mostly prone to painful diseases, they are more sensitive to noise than the general population. Noise affects both patients during the healing process and doctors during healthcare activities. Noise comes from the exterior and the interior of the medical ward. The renovations of the Romanian hospitals carried out while continuing to provide healthcare and the noise produced during medical procedures have a negative impact on the quality of medical staff performance and on the duration of patient's convalescence.

A hierarchy of the level of noise produced by medical activities was provided by numerous studies (1). To better understand the noise levels, it should be mentioned that the sounds produced by the take-off of an airplane are the equivalent of 100 dB A, a vacuum cleaner yields 70 dB A, a restaurant conversation equals 60 dB

A, the noise of a quiet urban neighborhood at night represents 35 dB A, a whispered conversation has 20 dB A and the sound breathing has 10 dB A (2). Due to the use of powered instruments, orthopedic surgery is the loudest medical procedure (between 66 and 100 dB A). Intensive care units may reach sound levels between 55 and 70 dB A. For instance, burn intensive care units have an average sound level of 70 dB A (3). In pediatric intensive care units, the average sound level was about 63 dB A (4). Neurosurgery, urology, cardiology and gastrointestinal surgery produce between 62 and 65 dB A. But this has not always been the case. In 1960, hospitals recorded an average sound level of 57 dB A during the day and of 42 dB A at night. In 2005, sound level averages reached 72 dB A during the day and 60 dB A at night. Above all, current technology was responsible for this increase (5), but also the continuous growth of population in urban areas, which makes hospitals more crowded than ever.

The diversity of clinical manifestations induced by pollution request individual and group-specific interventions for rehabilitation and the most successful possible professional reinsertion. That is why, the World Health Organization (WHO) has provided guidelines for specific noise levels within hospital units, recommending noise levels not exceeding 30 dB A at night and 35 dB A during the day. The International Noise Council recommends a maximum of 45 dB A during the day, 40 dB A in the evening and 20 dB A at night. The United States Environmental Protection Agency (EPA) recommends a sound level limit of 45 dB A during the day and 35 dB A at night for hospital patient rooms (6). The National Institute for Occupational Safety and Health (NIOSH) in the United States recommends noise levels which not exceed 40 dB A during the day and 35 dB A at night (3). Unpredictable disparate noise is regarded as more stressful than continuous noise (5). Sound sources may be mobile (relocating patients and equipment) or static (air conditioning and alarming systems).

One of the main sources of noise in hospital activity is represented by the conversations between medical professionals, between the doctor and the patient, between the patient and the visitors. However, medical rehabilitation is an area in which such discussions are more necessary, as long-term therapies require active involvement of the patient and family members or caregivers. Besides family and patient, the rehabilitation process requires a well-connected multidisciplinary team made of doctors, nurses, psychologists, physical therapists, occupational therapists, speech and respiratory therapists, dietitians and social workers. Medical information is delivered almost entirely verbally. Despite this, healthcare professionals should be aware of the need to maintain a muffled voice tone. On the other hand, the more crowded the hospitals become, the harder it is to maintain verbal communication at normal voice levels. Therefore, another critical issue is having to deal with the conflicting requirements of clear communication and the duty of confidentiality.

Further noise-limiting measures include restricting the number of visitors and isolating highly circulated areas with thick curtains and closing the doors, wearing soft-soled shoes, avoiding non-urgent activities at night, adjusting the television volume in hospital wards or the use of audio headphones (which may be quite uncomfortable and may even represent yet

another cause of hearing loss), setting mobile phones on silent mode, reducing the number of false alarms, which only desensitize the medical staff (7), repairing scraping doors and soundproofing of walls.

Hospital architecture should pursue to create a more silent environment, by taking the following measures: providing single patient rooms, replacing the right angles with curves, which produce less sound vibrations, sticking sound absorbing materials or panels on corridors, positioning the nursing ward in the center, with patient rooms surrounding it (8, 9). There are also causes of noise which are more difficult to limit and control, such as air conditioning and ventilators, noise-generating beds, computers, alarm systems for medical personnel, mobile phone conversations, opening and closing of cabinets and doors, crying and calls of patients in pain.

The negative effects of noise were acknowledged even by the ancient Greeks, who prohibited the noisy metal work in cities. Florence Nightingale, the founder of modern nursing, considered unnecessary noise as the cruelest absence of care (3).

Prolonged exposure to noise may induce temporary or permanent hearing loss, due to damaging the sensory cells in the organ of Corti. Although it was long argued that only industrial noise can affect the ear, numerous studies have reported the onset of hypoacusia in the general urban population, as well as the decrease of the onset age of presbycusis (age-related hearing loss, which is otherwise considered a physiological phenomenon). In professions in which noise reduction cannot be achieved, such as the army, conditioning or toughening of the ear through prior exposure to lower sound levels before exposure to harming noise, such as gunshots and explosions, was successfully used (10), but this is not an option in healthcare, where noise pollution is caused rather by repetitive and cumulative sounds than by acute and powerful sounds. The only piercing sounds are produced by the alarms of medical devices.

The treatment of adults having hearing loss is impaired by doctor-patient communication issues, as doctors have difficulties understanding the symptoms of the patients and patients do not understand treatment and prescription instructions (11). Auxiliary aids and services needed for effective therapy may have a major impact on treatment expenses, which are anyway high in medical rehabilitation, due to the long duration of therapy. Lip reading or written notes are merely ineffective and time-consuming solutions (12). However, influencing patient's decision to obtain hearing aids in form of equipment or services might be a major goal of healthcare workers, because people are not aware of the importance of the sense of hearing as compared to sight. Statistics show that the hearing aids are used in only 50% of the patients with hearing loss (13), which may not be the case in the more fashionable matter of wearing glasses. Rehabilitation doctors should also consider regular ear and hearing checks.

Noise can damage the body not only through the hearing process, but also by affecting skin, bones, joints and muscles. As noise requires even further raising of the tone of voice, it can also lead to voice disturbances (14). Noise was found to cause disturbances in the activity of the nervous system and in the function of the brain, by modifying the normal electrical pathways and overlapping some new disruptive pathways, as shown by electroencephalography.

One of the most severe negative effects on the health status of patients is sleep disturbance, which occurs at sound levels exceeding 50 dB A. During sleep, all physiological activities are minimized and even low-intensity noise can cause significant changes. The prolongation of time needed to fall asleep and the decrease of the period of deep sleep lead to fatigue, irritability, disorientation, the need for increased sedation and delayed healing and rehabilitation, due to the negative effects of sleep deprivation on the immune system (15). Quite frequently, rehabilitation patients need not only a sound night sleep, but also daytime rest.

Noise activates the sympathetic nervous system and the auditory–hypothalamic–pituitary axis. The exposure to powerful or prolonged noise leads to cardiovascular stimulation and vasoconstriction (hypertension, increased systemic vascular resistance, ischemic heart disease, cardiac arrhythmia, increased blood cholesterol), pituitary and adrenal gland stimulation, gastrointestinal system problems, immunosuppression and poor immune response to infection, impaired wound healing, a negative effect on cognitive tasks and altruistic behaviors, vertigo, agitation and irritability, insomnia and fatigue, headache and inappropriate conduct. Noise is a risk factor for neurosis, psych asthenia, hypertension, gastritis and gastric and duodenal ulcers, colitis, diabetes and hyperthyroidism. In pregnant women, prolonged exposure to noise leads to an increased risk of preterm birth and delivery of infants with low birth weight (15, 16). Noise decreases attention and concentration, speed and precision of movements, leading to poor labor productivity, especially in intellectual activities.

Due to the active role played by patients in medical rehabilitation, they are not immune to noise like the sedated patients in intensive care units, but rather strongly affected by noise. Doctors and nurses are also at risk for noise-induced changes in behavior, such as low interpersonal engagement, aggressive conduct and noncommunicative attitudes (5). Noise exposure may even lead to burnout in healthcare workers, as noise is experienced as a stressful situation, due to the evolution process, when sounds were a possible source of danger (17).

As more than half of all acoustic signals perceived in hospitals are related to human activities and speech, it is possible to control this phenomenon by changing human behavior. Hospital noise was sometimes replaced by music or by beneficial forms of sounds, such as relaxing white noise, which may be used for therapeutic purposes, especially for the cognitive rehabilitation of stroke patients (18, 19, 20).

Traffic noise outside the hospital is also a critical issue. Many studies have focused on controlling noise pollution within the hospital setting, neglecting the major impact of external noise caused by street traffic. Moreover, rehabilitation patients require long-term medical care at home, where they are affected by the urban noise experienced all over the city. All these negative effects of noise require a more accurate study of the sources of noise in cities, to help establish the existing levels and of accepted levels, as well as the necessary measures for reducing noise. Measures for the control of urban noise pollution include regulations and laws setting noise limits in human communities. Some of them are as follows: the functional zoning of populated areas (with special interest in the location of industrial facilities that are important sources of noise),

improving the road network and road traffic and, where appropriate, regulations on air travel to avoid the loudness discomfort caused by overflying human settlements, especially at nighttime (21, 22). Building rehabilitation clinics outside the congested urban areas in quieter locations might also solve the problem of street noise.

CONCLUSIONS

Medical staff working in rehabilitation units must be trained to limit the impact and the level of noise, by lowering the tone of voice and minimizing the sound levels of all technological devices. The purchase of new equipment must consider quieter medical appliances. On the eve of building the new Regional Hospital of Iasi, the reduction of hospital noise should be an objective equally important for the building design as earthquake safety, functionality and cleanliness.

HISTOPATHOLOGIC FEATURES OF PROGNOSTIC SIGNIFICANCE IN HIGH-GRADE OSTEOSARCOMA

Osteosarcoma is a malignant mesenchymal neoplasm characterized by bone production. Several types of primary high-grade osteosarcoma are recognized by the World Health Organization, including the "conventional" types encompassed by the chondroblastic, fibroblastic, and osteoblastic subtypes, among others. Despite heterogeneity in histomorphology, most high-grade osteosarcomas receive similar treatment, namely, neoadjuvant chemotherapy—typically consisting of doxorubicin, cisplatin, and high-dose methotrexate, followed by surgical resection and maintenance chemotherapy. Although a number of groups have assessed the contribution of clinical parameters—namely, patient age, sex, anatomic site of primary tumor, tumor size, and metastasis at presentation—in predicting survival outcomes for patients with osteosarcoma, there are limited data concerning histopathologic attributes. Histopathologic prognostic factors represent an essential component to the treatment stratification of many types of cancer. The authors suggest that detailed microscopic examination (tumor pleomorphism, mitotic activity, and morphologic subtype) yields useful prognostic information in high-grade osteosarcoma. In biopsy samples, necrosis and chondroblastic differentiation are adverse features. In resections, quantitation of the extent of residual viable tumor may be of greater clinical relevance than attempting to distinguish necrosis from other noncellular elements. In summary, the integration of clinical and microscopic features is a feasible and effective means for improving prognostication in patients with osteosarcoma. The effective stratification of patients using the proposed scoring system merits further investigation, ideally in prospective cohorts, to validate interobserver reproducibility and predictive ability (Chui MH, Kandel RA, Wong M, et al. Histopathologic Features of Prognostic Significance in High-Grade Osteosarcoma. *Arch Pathol Lab Med* 2016, 140 (11):1231-1242).

Department of Epidemiology

PARTICULARITIES OF THE ETIOLOGICAL STRUCTURE OF NOSOCOMIAL INFECTIONS IN HOSPITALS OF ORTHOPEDICS AND TRAUMATOLOGY PROFILE (Abstract): Determination of etiological structure of septic-purulent nosocomial infections (SPNI) in hospitals of orthopedics and traumatology profile. **Materials and methods**: there were analyzed 2013 strains of microorganisms isolated from the patients with SPNI. **Results**: it was established that Gram-positive microorganisms (63.19%) prevail in hospitals of Orthopedics and Traumatology profile, including *S. aureus* (39.19%), *E. faecalis* (12.76%), *S. epidermidis* (10,13%), followed by Gram negative microorganisms (35.56%), including *P. aeruginosa* (10.68%), *E. aerogenes* (8.64%), *E. coli* (4.32%), *C. diversus* (4.37%), *P. vulgaris* (2.58%), *Kl. pneumoniae* (1.54%). It was found that Gram positive strains prevail in young population, but Gram negative bacteria and fungi prevail in old population. Also, it has been shown that pathologic foci with associations of microorganisms predominate among old population, while monocultures prevail among young population. During the last years, it was observed an increase of SPNI caused by associations of microorganisms. **Conclusions**: The septic-purulent pathology has a polyetiological character in hospitals of orthopedics and traumatology profile, both in general population, as well in the hospital outbreaks among patients. **Keywords**: SEPTIC-PURULENT, NOSOCOMIAL INFECTIONS, GRAM-POSITIVE, GRAM-NEGATIVE, ETIOLOGICAL STRUCTURE.

Septic-Purulent Nosocomial Infections (SPNI) is one of the main problems of contemporary medicine (1, 2, 3), being caused by a variety of microorganisms. Thus, studying the etiological peculiarities per stationary profile, by age, methods of treatment is an important element in the epidemiological surveillance system (3-11). Also, the increase of frequency of association of two or more causative agents in the development of SPNI was underlined (1). The peculiarities of etiological structure of SPNI patients of orthopedics and traumatology profile are determined in the current study.

MATERIAL AND METHODS

This research is a descriptive transversal epidemiological study based on retrospective analysis of 2013 strains, a result from microbiological investigations performed in bacteriological laboratory of Traumatology and Orthopedics Clinical Hospital during years 2009-2010 and 2013-2014. The identification of microorganisms

in SPNI was performed per classical methods (Galeţchi 1997, Buiuc 1999), collecting the material from the wound was carried out using the moistened in physiological solution (0.9%) buffer.

RESULTS

The study of those 2013 strains of microorganisms, emphasized that the etiological structure of the traumatological septic-purulent infections (SPI) includes 18 species of microorganisms, the majority are opportunistic bacteria (tab. I). The Gram-positive microorganisms prevail, which is (63.2%). The causative agents in trauma SPI were represented by *S. aureus*-62.02%, *S. epidermidis*-15.02% and *S. saprophyticus*-1.10%. *Enterococcus* is 21.86%, prevailed *E. faecalis*-20.20%, followed by *E. faecium*-1.5% and *S. pyogenes*-0.07%.

Gram negative microorganisms group constituted 35.56% of the total number of strains detected from the patients with trauma SPI. *P. aeruginos*a-30.02%, and *E. aerogene*s-24.3%, followed by *E. coli*-12.30% prevailed. Microorganisms of the *Citrobacter* genus -17.59%, *Proteus*-10.06% and *Klebsiella*-5.30%. From 25 patients with SPI with infected wounds were isolated- *C. albicans* (1.24%).

TABLE I

The structure of microorganisms isolated from the patients with SPI in hospitals of orthopedics and traumatology profile

Groups	*Microorganism species*	Number of strains	% from the group	% of total strains
Gram-positive Microorganisms	*Staphylococcus aureus*	789	62.02	39.19
	Staphylococcus epidermidis	191	15.02	9.49
	Staphylococcus saprophyticus	14	1.10	0.69
	Enterococcus faecalis	257	20.20	12.76
	Enterococcus aecium	20	1.57	1.0
	Streptococcus pyogenes	1	0.07	0.05
	Total Gram positive	**1,272**	**100.0**	**63.20**
Gram-negative Microorganisms	*Escherichia coli*	88	12.3	4.40
	Enterobacter aerogenes	174	24.3	8.64
	Enterobacter cloacae	1	0.14	0.05
	Klebsiella pneumoniae	31	4.33	1.54
	Klebsiella oxytoca	7	0.97	0.35
	Pseudomonas aeruginosa	215	30.02	10.68
	Proteus vulgaris	52	7.26	2.58
	Proteus mirabilis	20	2.80	1.0
	Citrobacter freundii	39	5.44	1.89
	Citrobacter diversus	87	12.15	4.32
	Klebsiella oxytoca	7	0.97	0.35
	Acinetobacter calcoaceticus	2	0.28	0.1
	Total Gram negative	**716**	**100.0**	**35.56**
Fungi	*Candida albicans*	25	100.0	1.24
TOTAL		**2,013**	**100.0**	**100.0**

The distribution of the isolated strains taking into consideration the occupied rank in the total clinical picture (tab. I) demonstrates that in the general etiological structure of SPNI in hospitals of orthopedics and traumatology profile is as it follows: on the first place are the microorganisms of the *Staphylococcus* genus (*S. aureus*-39.19% and *S. epidermidis*-12.76%), followed by *P. aeruginosa*-10.61%, *E. faecalis*-9.49%, *E. aerogenes*-8.64%, *E.coli*-4.40%, *C. diversus*-4.32%, *P. vulgaris*-2.58%, *C. freundi*-1.89%, *Kl. pneumoniae*-1.54%, other microorganisms-3.46%.

There are 8 species of microorganisms that prevail in mixt infections, including the Gram-positive ones: *S. aureus*-in 31.52% cases of infections, *S. epidermidis*-5.35%, *E. faecalis*-19.48%; from the Gram-negative microorganisms *P. aeruginosa* in 10.86%, *E. aerogenes*-10.25%, *E. coli*-5.04%, *Citrobacter*-7.35%, *Proteus*-5.04%, *Klebsiella*-2.01%; other microorganisms 2.87% (fig. 1).

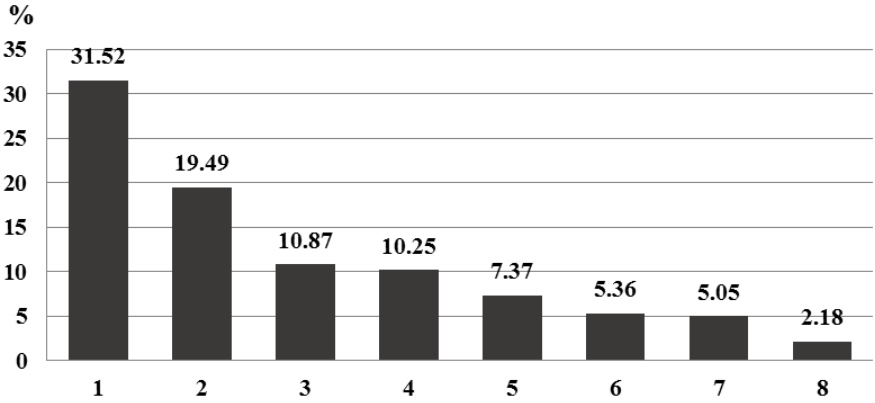

Fig. 1. The species of microorganisms prevalent in associations of pathogens according to the occupied rank: 1- *S.aureus; 2- E. faecalis; 3- P. aeruginosa; 4- E. aerogenes; 5- Citrobacter; 6- S.epidermidis; 7- E.coli and Proteus; 8- Klebsiella*

Peculiarities in the structure of microorganisms in relation with the patients' age. It has been found that Gram-positive microorganisms prevail among young age groups, the share part of which diminishes with age, from 74.68% in people up to 20 years, up to 55.17% in 70 years and older persons. And vice versa, Gram negative microorganisms and fungi prevail in the old age groups, with an increasing rate from 25.3% and 0.0%, respectively, among patients under the age of 20 years, up to 42.67% and 2.15% respectively, among patients aged 70 years and older (tab. II).

At same time, it has been found that the number of isolated strains from pathological foci varies and is in direct relation to the age of patients (tab. III, fig. 2). Thus, monocultures were isolated from pathologic foci in young patients, while the associations from 2-5 strains of microorganisms in elderly. This phenomenon is demonstrated both by the growing share of associations of microorganisms, detected in patients with SPNI according to the age, and by calculating to 1,000 patients in each age category. One strain was isolated predominantly in patients aged 16-39 years that is

1303,7 per 1000 patients. While associations from 2-5 strains are prevalent in patients over 40 years and more-1648,3 strains per 1,000 patients, the statistics difference being confirmed ($t=3.95$, $p<0.001$).

The analysis of evolutionary changes in the structure of monocultures and associations of microorganisms. It is interesting both the epidemiological and clinical evolution of the number of strains isolated from patients with SPNI-in associations or monocultures. During years 2009-2010 and 2013-2014, 2013 respectively 1,857 strains of microorganisms from 1,280 and 1,089 patients respectively were isolated, the average number of isolate strains from a patient being 1.57 and 1.71 respectively some foci, which demonstrates the increased number of patients with SPNI affected by associations of microorganisms (tab. IV).

TABLE II

The structure of microorganisms isolated from the patients with SPI, per the patients' age

The group of micro-organisms	Indices	Age category (years)						
		≤20	**20-29**	**30-39**	**40-49**	**50-59**	**60-69**	**≥70**
Gram positive	No.	59	156	205	207	315	202	128
	%	74.68	67.82	65.70	64.68	62.25	60.29	55.17

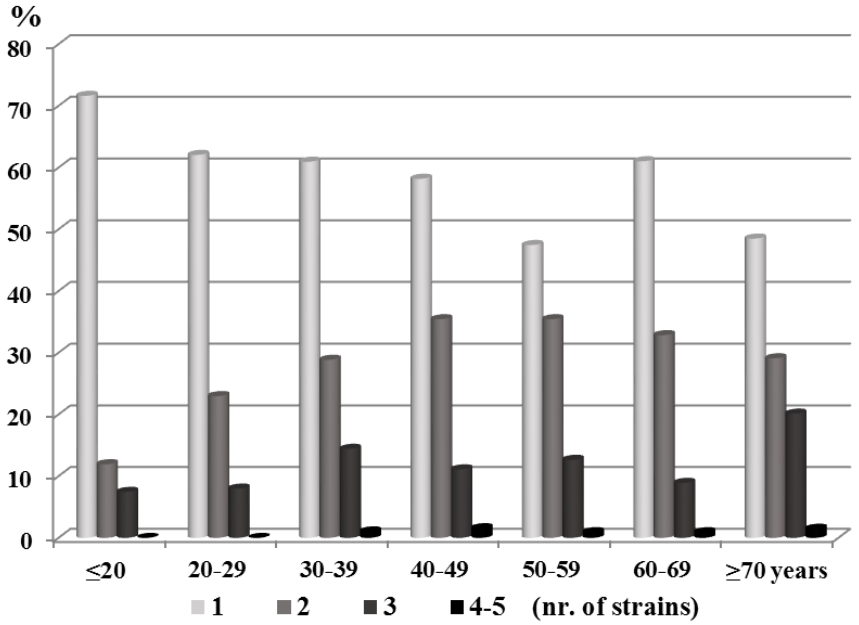

Fig. 2. Strains' number distribution isolated from pathologic foci according to the age of patients

TABLE IV

Distribution of cases of traumatology SPI according to the number of strains isolated from the pathologic focus

Periods	Indices		Number of strains of microorganisms detected in patients with SPNI					Total
			1	2	3	4	5	
Years 2009-2010	No. of patients	Abs.	725	390	153	11	1	1,280
		%	56.64	30.47	11.95	0.86	0.78	100.0
	No. of strains	Abs.	725	780	459	44	5	2,013
		%	36.01	38.74	22.80	2.2	0.25	100.0
Years 2013-2014	No. of patients	Abs.	526	372	178	12	1	1,089
		%	48.30	34.16	16.35	1.10	0.09	100.0
	No. of strains	Abs.	526	744	534	48	5	1,857
		%	28.33	40.06	28.76	2.58	0.27	100.0

It was emphasized that the mono-etiological nature of septic-purulent infections foci, in the multiannual dynamics, is decreasing from 56.64% of investigated patients or 36.01% of isolated strains-between 2009-2010, up to 48.30 % of patients or 28.33% of detected strains-in 2013-2014, being confirmed the statistical difference ($t=2.89$, $p<0.01$). And vice versa, we found an increase of polyetiological aspect. There were isolated from 2 to 5 septic-purulent strains 43.36% of those

investigated, that is 63.99% of all the isolate ones. During the next period, 2013-2014, there were found associations of 2-5 strains of microorganisms in 51.70% of the investigated ones with septic-purulent infections, being 71.67% of the total number of strains (tab. IV, fig. 3).

The number of patients with associations of microorganisms increased by 8.34% in multi-annual dynamics, but the number of microorganisms isolated in associations increased by 7.68%.

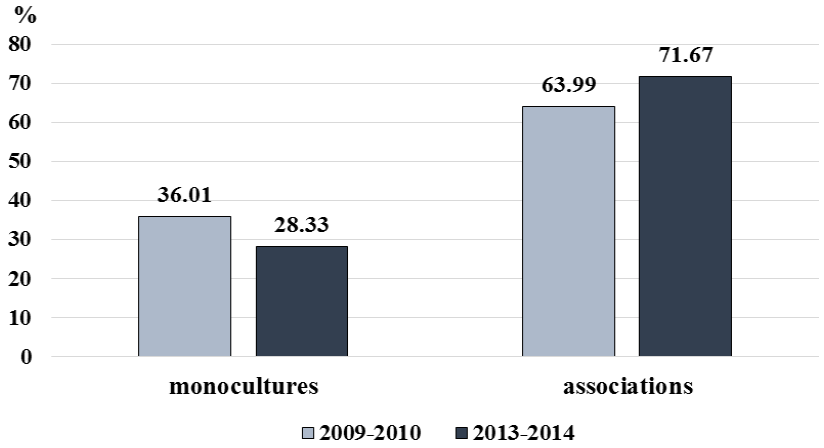

Fig. 3. The distribution of patients with SPI in hospitals of ortopedopedic and trauma profile with monocultures and associations of microorganisms

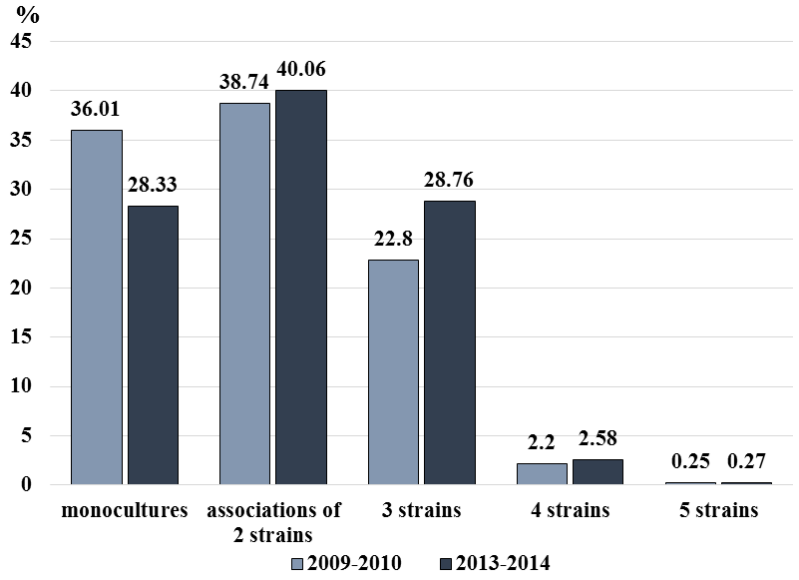

Fig. 4. Comparative distribution of SPI cases according to the number of strains isolated from the pathologic focus, over periods

Therefore, from the total number of isolated strains 63.99% (years 2009-2010) and 71.67% were proven to be in various associations (t=2.75, p<0.01), including 38.74% and respectively 40.06%-associations of two species-1.32% more in the second period; 22.80% and respectively 28.75%-associations from three species-increasing by 5.95% compared to the previous stage; 2.2% and 2.58% respectively-associations from four species-growing by 0.38%; and 0.25% and respectively 0.27%-associations from five species (tab. IV, fig.4).

CONCLUSIONS

Our researches showed that the septic-purulent pathology in hospitals of orthopedics and traumatology profile has a polyetiological character, both in general, and in the infectious foci in patients. The Gram-positive microorganisms prevail (63.19%) compared to Gram-negative ones (35.56%).

We have established that the SPNI are caused mainly by monocultures and Gram-positive bacteria in patients of young age, while SPNI with Gram-negative, fungi and associations with 2-5 strains, prevail in old age.

We have determined that the rate of patients with monocultures decreases in multi-annual dynamics and, *vice versa*, we have registered an increasement of cases caused by the associations of multiple microorganisms.

IMPORTANCE OF DENTAL MAXILLOFACIAL AESTHETICS IN DENTAL THERAPY (Abstract): The recent development of aesthetic dentistry reflects a concentration of the dentists' concern for satisfying patients' requests for an aesthetic appearance of their teeth. Modern dentistry combines medical treatment with the art of aesthetic restorations. Over the years, the restoration of the facial harmony has changed its character, from random to necessary, and from optional to compulsory, as the aesthetic defects have become less and less accepted. **Aim**: Contributions to understanding the principles that must be respected in dental-facial aesthetics and their application in various accessible prosthetic techniques that lead to significant improvement of the aesthetic appearance of the final restoration. **Material and methods:** The study included 22 (aged 40 to 80 years) patients (mean age: 60 years), presenting to the Department of Clinical Dentistry for different types of prosthetic restorations. **Results and discussions:** Taking into consideration the aesthetic principles and criteria, the prosthetic restorations in two similar clinical situations were performed using a different methodology. **Conclusions:** To grant the actual interventions the necessary provisions of true clinical success, the dentist must have and develop the skills that allow him/her to be valued as both a scientist, and an artist. **Keywords:** THERAPY, AESTHETICS, DENTAL-FACIAL, RESTORATION.

Aesthetics is defined as "the science of beauty in nature and art." Although easy to be accepted, such an interpretation contradicts several famous statements of giants of the universal cultural heritage: Plato – "Beauty is virtual" -, Hegel – "beauty cannot be an exact science" -, or Leonardo de Vinci – "Human beings represent the sensitive vector that gives life to essential beauty" (1,2,13).

The well-known Frush and Fischer's SPA triad: sex, personality, age (3) is critical in personalization and choice of the optimal therapeutic solution, as well as other criteria of dental-facial and dental-somatic harmony and, through symmetry, harmony of proportion of the rhythms (repeating, at equal intervals, a certain element of a certain kind), by harmonizing the form with the function, by dissimulating the prosthetic artifice.

Evaluation are made by taking into con-

sideration the components of the aesthetics of the smile: facial, dental-facial, and dental.

Regardless of definition, aesthetics is a reality that reaches all fields of life. Even if the aesthetic emotion is specific to art, for modern people it became necessary in daily environment, daily life, because, as Darwin, Herder, Nietzsche believed (4), the beauty and aesthetic feeling are very important for the development of individual and social life (14).

Dental conditions, aggravated with advancing age, essentially change the aesthetic appearance, which impacts the psychic of the patients, sometimes triggering psychoses (3, 6).

Dental-maxillofacial aesthetics needs attention, so that the treatment is individualized per the patient's wishes.

The goal of the study was to understand the basic principles that must be respected in dental-facial aesthetics and to prove the mastering of these principles by applying them in dental-facial aesthetics, including various prosthetic techniques that help to significantly improve the aesthetic appearance of the final restorations.

MATERIAL AND METHODS

We conducted this study in a group of 22 patients, aged 40 to 80 years (mean age: 60 years) presenting to the Department of Clinical Dentistry for different types of prosthetic restorations.

Physical examination was performed in all subjects, having medical records containing details related to involution of physiognomy and results of complementary examinations (orthopantomography, study model, biometric measurements), useful in making the diagnosis.

During clinical facial examination, we paid attention to several parameters, useful for restorations: contour of the face, with dominant features (nose, cheekbones, forehead, lips etc.); profile features; existing facial asymmetries; mandible-cranial relationship.

Intraoral examination aimed at highlighting the elements that can contribute to alteration of physiognomic function: teeth, periodontium, edentulous ridges, and occlusal ratios. Special attention was paid to bone reorganization, size of alveolar ridges and the relations between these, and potential prosthetic space. Examination of the old dentures revealed elements that might compromise the physiognomic appearance: arches, false gums, damaged margins (length, depth, casting), hygiene status.

For statistical analysis ANOVA and T-student tests were used, and the database was managed with MS Office Excel and Epi Info 2000.

RESULTS

It was proven that, next to the other dental specializations, dental prosthetics brings substantial contributions to morphological and functional restoration of the stomatognat system of the elderly, compromised by these conditions (5). The last decade brought an impressive volume of research in dental prosthetics, which determined reorientations in therapeutic concepts, together with new treatment means (6).

General principles of dental-facial restorations are individualized, per age and gender (7).

Age-group and gender distribution of patients showed that most patients were female (7 male patients – 31.81% and 15 female patients – 68.19%) (fig. 1).

Patient distribution by dental syndromes revealed a high prevalence of total (mono-

or bi-maxillary) and subtotal edentation.

Patient distribution by syndromes: total edentation - 3 cases (13.63%); subtotal edentation - 6 cases (27.27%); partial edentation - 2 cases (9.09%); dental crown lesions - 5 cases (22.72%); periodontal disease - 4 cases (18.18%); malocclusions - 2 cases (9.09%) (fig. 2).

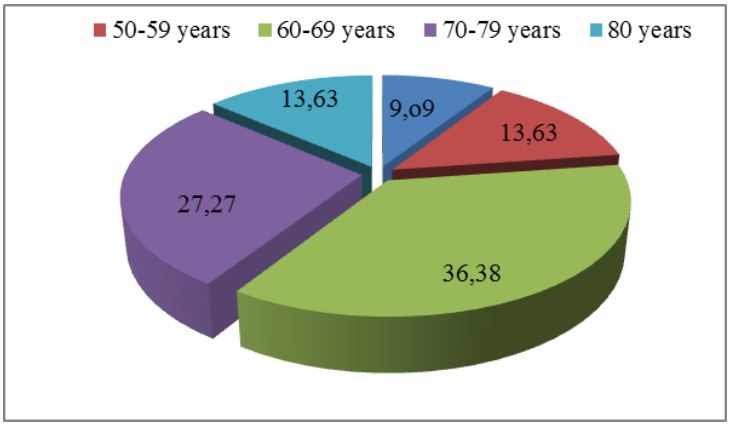

Fig.1. Age-group distribution of patients (years)

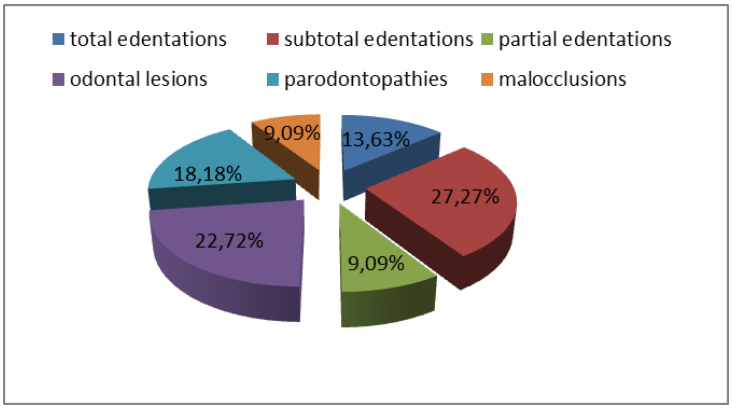

Fig. 2. Distribution of patients by syndromes

These values are irrelevant as in most of the cases the syndromes were associated.

History indicated the reasons for requesting the dental treatment and a preponderance of the female gender presenting for restoring their physiognomic function.

Of the 22 patients, in 8 elderlies (36.38%) with damaged removable dentures and 6 (27.27%) with conservative dental restorations the most common complaints were related to functional dissatisfaction related to the material, manufacturing technology requesting their restoration or re-optimization. Some of the patients did not have dentures – 3 (13.63) not trusting their wishes would be met.

Disorders of the stomatognat system frequently have a negative effect on dental-facial aesthetics. The impactation of physiognomic appearance in elderly is deter-

mined by dental, coronary lesions, with or without loss of substance, periodontal conditions, integrity loss of dental arch due to edentation and dental migrations, occlusion disorders, and disturbance of the mandibular-cranial relationship.

In all 22 cases included in the study, local clinical examination revealed important clinical changes of stomatognat system, prosthetic field, providing useful information for choosing and positioning frontal teeth, distributing edentulous spaces, placing the occlusal plane, moulding the vestibular side or the margins, in removable dentures.

Intraoral examination revealed the existing oral pathology, in some cases with important consequences on the patient's physiognomy (fig. 3).

Fig. 3. Aspect of oral pathology in elderly (Collection of the Clinic)

The dental and periodontal status proved to be heterogenous, a consequence of involution phenomena and/or associated pathology: there were patients with more or less complete dentition, - 4 cases (18.18%) with coronary odontal lesions, periodontal diseases, malocclusions, and partial or total edentation.

Examination of old dentures brought useful information related to technology and functional satisfaction, which served as an important guide for new dentures – 11cases (50.00%) (fig. 4).

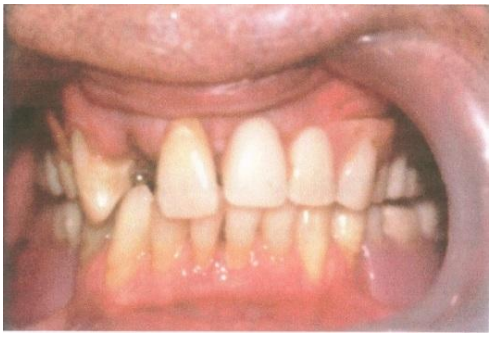

Fig. 4. Examining old dentures (Collection of the Clinic)

Dental and prosthetic treatment offered in 9 cases (40.90%) multiple possibilities of recovery of functions of the stomatognat system, physiognomic appearance, influenced by the oral pathology, but also by the involutive process. Although the patient was helped to rebuild self-esteem by the restoration of his physiognomic appearance, it should not prevail over the other fundamental principles of dental practice (7, 8).

The aesthetic principles and criteria of prosthetic restoration therapy were applied in all 22 cases included in this study. Thus, we used the ceramic metal procedure in 7 cases (31.81%), in which the aesthetic success depended on specific problems related to the form of preparation and the nature of the dental-prosthetic joint.

Since the ceramic metal restorations were manufactured correctly, their durability is better than the one of conventional ceramic, due to their metal infrastructure and low fusing porcelain, very durable, with better binding forces than the cohesion forces of porcelain itself – 11 cases

(50.00%) cases.

Of the 22 cases included in the study, 5 (22.72%) cases suffered from dental crown lesions at different levels (11, 17, 18) with rapid caries progression, not allowing the preservation of dental crowns and requiring immediate ceramic metal therapy, this time using the substitution method and two-piece prosthetic technique (fig. 5).

Fig. 5. Dental crown lesions (Collection of the Clinic).

In general, the preparation technique resembled that of any other type of ceramic metal crown. On vestibular facet, we chose the 90° angle threshold preparation, as well as Jacket crowns made of porcelain.

The use of porcelain margin technique in bevel preparations, with tilted or knife-edge thresholds was contraindicated, since the marginal porcelain would be very thin, impossible to fit properly and would easily fracture (11, 12, 14). This technique allows the use of any modern materials for manufacturing the models, including epoxy resins, copper, plaster, and improved plaster.

DISCUSSION

As other authors stated (1, 2, 9), our aesthetic goals were to reproduce all parameters, except for the ones related to placing the gingival margin, gingival zenith and the cervical coronary third technique.

In terms of restoration, from depth to surface, we applied a preparation to the cervix, especially at vestibular level where it should be an optimal space for applying metal and porcelain layers, and especially opaque, in a sufficiently thick layer, that can effectively mask the subjacent metallic structure.

As other authors stated (10, 11) provisional dentures helped us reach our aesthetic goals, which, besides proper protection of organic structures, provided the restoration of morphological and functional integrity of the dental arch, with the possibility of immediate social reinsertion (9, 11).

CONCLUSIONS

Contributions to understanding the principles that must be respected in dental-facial aesthetics and their application in various accessible prosthetic techniques that lead to significant improvement of the aesthetic appearance of the final restoration. The general principles based on dental facial aesthetic restoration/of aesthetic restorative dentistry were individualized according to age and gender, while dental syndromes allowed an analytical and critical estimation of such elements as: proportions, symmetry and diversity.

Elderly patients with damaged removable dentures complained of functional problems and expressed dissatisfaction with the material and manufacturing technology, which created physiognomic problems, requesting their restoration or re-optimization (.

Although the use of metal and porcelain gave acceptable results, better safety was accomplished by using a combination in which the difference between the thermal expansion coefficients was higher.

XRCC1 Arg194Trp AND Arg399Gln POLYMORPHISMS AND RISK OF NON-HODGKIN LYMPHOMA IN A ROMANIAN POPULATION (Abstract): *XRCC1* polymorphisms may alter the individual's capacity to repair DNA damages and may increase the risk for developing different types of cancer, including Non-Hodgkin Lymphoma (NHL). The purpose of our study was to investigate the association between *XRCC1* Arg194Trp and Arg399Gln polymorphisms and risk of NHL, in a case-control study consisted of 81 patients with NHL and 113 healthy controls. The polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) methods were performed to determine the *XRCC1* genotypes. A statistically significant association was observed between the *XRCC1* Arg194Trp polymorphism and risk of NHL ($p < 0.0001$, OR = 7.01, 95% CI = 2.488-19.753) in both male and female. We found no association between NHL and control groups with respect to *XRCC1* Arg399Gln polymorphism ($p = 0.4867$, OR = 1.346, 95% CI = 0.5822-3.111). Also, we did not find differences between the *XRCC1* polymorphisms and NHL risk taking into account the IPI score, ECOG performance status, Ann Arbor stage and the treatment outcome ($p > 0.05$, for all comparisons). Our results suggested an increased risk for NHL regarding the *XRCC1* Arg194Trp polymorphism in a Romania population, while *XRCC1* Arg399Gln polymorphism is not associated with NHL. Further work is needed to validate these results on a larger sample study. **Keywords:** *XRCC1*, GENE POLYMORPHISM, NON-HODGKIN LYMPHOMA.

Non-Hodgkin lymphoma (NHL) represents a heterogeneous group of malignancies. According to GLOBOCAN (1) the incidence of NHL for both sexes is 2.7 per 100,000 persons and in the past 50 years, the incidence has increased significantly, being higher in men than in women (2). In Romanian population the incidence of NHL is estimated at 1566 cases men and women per year (1).

A number of exogenous and endogenous exposures, such as virus infections, immune dysfunction, benzene and other solvents and alteration in capacity to repair DNA, have been proposed as risk factors for NHL (2-6).

Recent studies have shown the association between single-nucleotide polymorphisms (SNPs) in DNA repair genes and susceptibility to NHL (7-18). X-ray repair

cross-complementing group 1 (*XRCC1*) protein plays an important role in the DNA repair mechanisms, specifically in base excision repair pathway and produces amino acid substitutions (2-3, 5-6). *XRCC1* is involved in the repair of DNA single-strand breaks formed by exposure to ionizing radiation and alkylating agents (6, 14).

Many polymorphisms of the *XRCC1* gene on chromosome 19q13.2 have been identified and have been registered in the SNP database (http://www.ncbi.nlm.nih.gov/SNP). These polymorphisms might contribute to the risk of cancer, including NHL (9-11, 15-17). Thus, the most studied polymorphisms in hematological malignancies in *XRCC1* gene are Arg194Trp, Arg399Gln and Arg280His (2-18).

Our aim was to evaluate the effect of *XRCC1* Arg194Trp and *XRCC1* Arg399Gln polymorphisms on the risk of NHL within a case-control study conducted in Romania. We also investigated the influence of *XRCC1* polymorphisms on treatment outcome and disease stage patients with NHL.

MATERIAL AND METHODS

The patients' group consisted of 81 Caucasian adults diagnosed clinically and histologically with NHL, according to World Health Organization classification (19), at the Hematology Clinic I from Emergency Clinical County Hospital Tîrgu Mureș, Romania. Medical reports and laboratory data of the patients with NHL were reviewed to evaluate histologically subtypes of NHL, the International Prognostic Index (IPI) score, The Eastern Cooperative Oncology Group (ECOG) performance status, Ann Arbor stage, treatment outcome and survival rate.

The control group comprised 113 healthy individuals with no history of cancer or other chronic diseases. The mean age in NHL group was 59.96 years and in the control group was 65.26 years.

The study was approved by the Ethics Committee of the University of Medicine and Pharmacy Tîrgu Mureș, Romania (no. 111/12.14.2015) and written informed consent was given according to the principles of the Declaration of Helsinki.

DNA samples were extracted from fresh peripheral blood using the Quick-gDNA MiniPrep kit (Zymo Research, USA) and the polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) methods (20) were performed to determine the *XRCC1* genotypes.

All statistical analysis were performed using GraphPad InStat software. The Chi-square test and Fisher's exact test (two-sided) were used to compare genotype frequencies ($p < 0,05$). To estimate the associations between genotypes and risk of NHL were also calculated the odds ratios (OR) and 95% confidence interval (95% CI) for OR.

RESULTS

The allele and genotype distribution of the *XRCC1* Arg194Trp and Arg399Gln polymorphisms among the patients and controls are shown in table I.

A significant association was observed between the *XRCC1* Arg194Trp (Arg/Trp) polymorphism and risk for developing NHL ($p < 0.0001$, OR = 7.01, 95% CI = 2.488-19.753) in both male and female.

No significant associations were found in females between controls and patients for *XRCC1* Arg399Gln (Arg/Gln, Gln/Gln) and *XRCC1* Arg194Trp (Trp/Trp) polymorphisms and NHL risk.

No.- number, Ref. – reference category

In this study, a decreased risk for developing NHL was observed between NHL male patients and male controls with respect to *XRCC1* Arg399Gln SNP (OR = 0.5102, 95% CI = 0.2153-1.209), but not statistically significant. However, no association was obtained in women regarding *XRCC1* Arg399Gln combined heterozygous and variant homozygous genotypes and NHL risk (p = 0.4867, OR = 1.346, 95% CI = 0.5822-3.111).

In table II are summarized demographic and clinical characteristics of the NHL cases according to the genotype of the *XRCC1* Arg194Trp and Arg399Gln polymorphism.

Furthermore, we observed that an III or IV Ann Arbor stage, an increased ECOG performance status and increased IPI score were associated with poor survival time for NHL and a higher resistance to treatment. The lowest median survival time in our study was 31.2 months in *XRCC1* Trp194Trp polymorphism and 29.62 months in *XRCC1* Gln399GLn polymorphism.

There were no significant differences between *XRCC1* Arg399Trp and *XRCC1* Arg399Gln polymorphisms and ECOG performance status and IPI score, respectively (p > 0.05, for all comparisons). Also, no differences were found regarding NHL patients' outcome (resistant, partial remission and complete remission to treatment) and investigated SNPs (p = 0.3482, p = 0.6959).

We noticed that 8 of our patients had the variant genotype for both studied polymorphisms of the *XRCC1* gene, 5 of them

were females (4 patients with Arg/Trp + Arg/Gln, 3 with Arg/Trp + Gln/Gln and 1 patient with Trp/Trp + Arg/Gln). In the control group, we found that a male patient (70 years old) had the Arg/Trp + Arg/Gln genotype.

The frequency of *XRCC1* combined variant heterozygous and homozygous genotypes were higher in NHL patients than in controls. We may presume that presence of combined variant genotype may be associated with the risk of developing NHL in the investigated cohort.

DISCUSSION

In the present study, we investigated a possible association between the *XRCC1* polymorphisms (Arg194Trp and Arg399Gln) and risk for developing NHL in a population from Transylvania region. To our knowledge, our study is the first to analyze the association of the *XRCC1* Arg194Trp and Arg399Gln polymorphisms with NHL in a Romanian population.

Defects in repair pathways induced by endogenous and exogenous carcinogens can lead to mutations implicated in cancer pathogenesis (2-6). However, previous studies reported contradictory results (2, 6-18). Thus, we hypothesized that DNA base excision repair gene *XRCC1* Arg194Trp and Arg399Gln polymorphism may increase or decrease the risk of NHL.

In this study, we found that *XRCC1* Arg194Trp polymorphism is associated with an increased risk of NHL. This association is confirmed in a study performed by Kim I et al. (7) in a Korean population, showed a significantly increased the risk of diffuse large B-cell lymphoma (DLBCL) and Hill D et al. (8) revealed that the *XRCC1* 194Trp allele was associated with a slightly increased risk (1.4-fold) of developing NHL.

In a meta-analysis performed by Li Y et al. (9) in 2010 on 13 case-control studies, variant genotypes of *XRCC1* Arg194Trp polymorphism was associated with an increased risk of NHL in the Asian population, while *XRCC1* Arg194Gln polymorphism had a decreased risk for this disease.

In contradiction, in a recent meta-analysis conducted by Tang L et al. (21) of 20 case-control studies no significant association was observed between NHL and *XRCC1* Arg194Trp polymorphism. Similar findings were observed in a small children cohort with B-cell lymphoma (33 patients and 52 controls) that frequency of *XRCC1* Arg194Trp polymorphism was significantly lower in patients than in the control group ($p = 0.005$). No association was reported between *XRCC1* Arg194Trp allele and DLBCL in Australian population (2).

In addition, no SNP variants of *XRCC1* Arg194Trp, Arg280His and Arg399Gln alone were found to be related with the risk of NHL or histologic subtypes of NHL in a Chinese population (10). However, Liu J et al (10) reported that two combinations of SNP variants were associated with an increased risk of NHL. Moreover, they revealed that Arg399Gln variant allele was associated with risk of follicular lymphoma among heavy smokers.

In the present study, *XRCC1* Arg399Gln polymorphism was no associated with the risk of NHL. The lack of association for the *XRCC1* ArgGln399 variants with NHL was also observed in a Japan population described by Matsuo K et al. (22) (372 cases with malignant lymphoma and 500 controls) and in a comprehensive meta-analysis conducted by Du L et al. (11) in 2015 on 27 case-control studies. Moreover, Du L et al. (11) suggested that *XRCC1* Arg399Gln polymorphism might be a risk factor for leukemia in the Asian population, but not in malignant lymphoma or in the European population. Therefore, we can assume that the variant heterozygous and homozygous genotypes for *XRCC1*

Arg399Gln polymorphism has a protective role in NHL and other types of malignancies (9, 11, 21-22).

In contrast to our findings, Veropaeva E et al. (12) demonstrated that the *XRCC1* Arg399Gln polymorphism (Gln/Gln) was associated with a significantly increased risk of aggressive NHL in 42 cases. On the other hand, in a study conducted in America, El-Zein R et al. (14) observed that *XRCC1* Arg399Gln SNP had a significantly increased risk of Hodgkin's disease.

According to Kim H et al. (23), *XRCC1* Arg399Gln polymorphism had a decreased risk for NHL in a Korea population in a case-control study consisted in 694 cases and 1700 controls (OR = 0.80, 95% CI = 0.66–0.96, p = 0.02).

Our results suggested the presence of 8 cases of combined genotypes with NHL and another one in the control group. In a study from 2014 performed by Li SX et al. (15) on 282 cases and 232 controls it was shown that combined genotypes *XRCC1* 399-280-194 were not associated with NHL risk. According to Kim I et al. (7), *XRCC1* haplotype A (194Arg-280Arg-399Arg) was associated with a decreased risk of DBCL (OR = 1.38; 95% CI = 1.05-1.80; P = 5 0.019).

The current study is the first to evaluate the differences between analyzed *XRCC1* Arg194Trp and *XRCC1* Arg399Gln polymorphisms and risk of NHL taking into account the IPI score, ECOG performance status, Ann Arbor stage and treatment outcome and there were no significant differences (p > 0.05, for all comparisons).

There are few data that evaluated the response to treatment or survival chemotherapy or radiotherapy associated with *XRCC1* polymorphisms. For example, Kim K et al. (24) reported an increased association between variant genotypes of the *XRCC1* Arg194Trp polymorphism in patients with cervical cancer and treatment response (platinum-based neoadjuvant chemotherapy).

According to Kim I et al. (7) no relation was noticed between *XRCC1* Arg399Gln genotypes and response to treatment, results similar to our findings.

However, our study has following limitations. First, the sample size group is relatively small compared to previous studies and could influence the statistical power. And the second, the unknown environmental factors were not considered, this could modify the effect of the *XRCC1* SNPs.

CONCLUSIONS

The present study demonstrates that the variant genotypes of the *XRCC1* Arg194 Trp polymorphisms were associated with an increased risk of NHL in a Romanian population. On the other hand, we can assume that *XRCC1* Arg399Gln does not represent a risk factor for NHL.

Thus, further investigations on larger sample groups are needed to clarify the association between *XRCC1*polymorphisms and susceptibility to NHL.

ADENOCARCINOMA AND TUBERCULOSIS OF THE SIGMOID COLON AND FALLOPIAN TUBE – A RARE ASSOCIATION. A CASE REPORT AND REVIEW OF THE LITERATURE (Abstract) Association of adenocarcinoma and tuberculosis (TB) of the sigmoid colon is a rare clinical condition even in an endemic country as Romania, with challenging diagnosis and treatment. **Case report**. We present the case of a 57-year-old female patient who was admitted on emergency basis for a diagnosis of obstructive sigmoid adenocarcinoma. The patient was operated on and it an obstructive sigmoid tumor with serosal invasion, adherent (invading) to the body of uterus and left adnexa and urinary bladder serosa, no liver or peritoneal metastases. A sigmoidectomy was performed *"en bloc"* with subtotal hysterectomy, left adnexectomy and extramucosal cistectomy. The histopathological exam showed a moderately differentiated, ulcerated adenocarcinoma, widely infiltrating the colon wall invading the myometrium. Ziehl Neelsen (ZN) stain identified the presence of metachromatic bacillary structures in the colonic wall, lymph nodes and adnexal areas. Postoperative course was uneventful and the patient was discharged 10 days postoperatively in good clinical condition. After one year when the patient completed the full course of antitubercular drugs, a thorough work-up was performed. Colonoscopy, CT of the thorax, abdomen, pelvis showed no signs of recurrence while tumoral marker CEA (1,62 ng/ml – n<3,4) and QFT (Quantiferon-TB Gold) test were within normal range. **Discussion and conclusion**. Although digestive tuberculosis is included in differential diagnosis for those patients presenting abdominal pain or obstructive digestive symptoms in endemic regions, in this case the absence of TB infection criteria and positive endoscopic biopsy for colonic adenocarcinoma did not allow a complete pre- or perioperative diagnosis. **Keywords**: ADENOCARCINOMA, TUBERCULOSIS, SIGMOID, FALLOPIAN TUBE.

Association of adenocarcinoma and tuberculosis (TB) of the sigmoid colon is a rare clinical condition even in an endemic country as Romania. As preoperative diagnosis of colon cancer routinely poses no difficulties, the association of malignancy and TB may be challenging, both in term of diagnosis and treatment. Due to the intricate presentation of these two disorders, in most of the cases pathology examination of

the surgical specimens ultimately reveals the accurate diagnosis in most of these cases. It is to be elucidated if the association of these lesions is a coincidence or there is an etiological relationship, as ulcerative colitis and Crohn's disease are proved to be a premalignant condition for colon cancer.

CASE REPORT

We present the case of a 57-year-old female patient who was transferred in our department on emergency basis from the gastroenterology department. The patient had no personal or collateral relevant history (including TB) and was initially admitted in the gastroenterology unit for persistent lower quadrants abdominal pain, change in bowel habit (diarrhea followed by constipation) fatigue and altered general status. A diagnosis of sigmoid carcinoma was established by colonoscopy that revealed a tumor at 40 cm from the anal verge, with macroscopic and microscopic features of an adenocarcinoma (fig. 1).

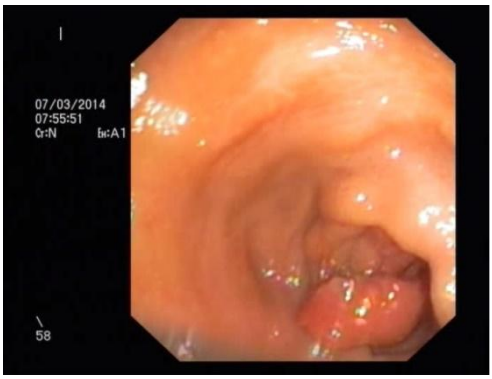

Fig. 1. Colonoscopy aspect

The thorax radiography was normal whereas ultrasound examination of the abdomen revealed no liver or peritoneal deposits. Shortly after colonoscopy the patient developed symptoms of lower intestinal obstruction and was referred to surgery. The physical examination at admittance in our unit revealed a distended abdomen, tenderness in the left lower quadrant where an imprecisely defined mass was palpable and exaggerated bowel sound; rectal touch and vaginal examination were inconclusive. Except for a mild microcytic anemia, the lab tests were within normal range. Hidroaeric levels were present on plain abdominal X-ray.

Following a swift preoperative preparation, the patient was operated on through a median laparotomy; the exploration of the peritoneal cavity revealed an obstructive sigmoid tumor with serosal invasion, adherent (invading) to the body of uterus and left adnexa and urinary bladder serosa, no liver or peritoneal metastases. Under these circumstances, a sigmoidectomy was performed *"en bloc"* with subtotal hysterectomy, left adnexectomy and extramucosal cistectomy. Postoperative course was uneventful and the patient was discharged 10 days postoperatively in good clinical condition.

Resection pieces were examined at the Pathology Department of "Sf. Spiridon" Hospital. The anatomic and pathological examination consisted in the macroscopic evaluation of the colonic tumor and subsequently the fragments were fixed in 10% neutral formalin and processed for histological techniques including the classic paraffin, cutting on microtome 4µm sections and stained with Hematoxylin-Eosin (HE) and Ziehl Neelsen (ZN) for tuberculous bacillary identification.

The histopathological exam showed a moderately differentiated, ulcerated adenocarcinoma, widely infiltrating the colon wall (fig. 2) complicated with parietal fis-

tula and granulation tissue (in which also found food debris). The infiltrative tumor interested the external myometrium about 2 mm (fig. 3). In the lymph nodes, the adherent colon and the omentum numerous granulomatous lesions, with central caseous necrosis and tendency to confluence were identified (fig. 4). The tuberculous lesions were also found in the left fallopian tube with second involvement of the ovary. Ziehl Neelsen (ZN) stain identified the presence of metachromatic bacillary structures in the colonic wall, lymph nodes and adnexal areas (fig. 5).

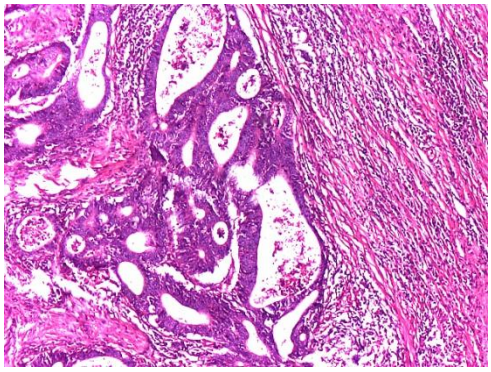

Fig. 2. Moderately differentiated, ulcerated adenocarcinoma, HE, x 4

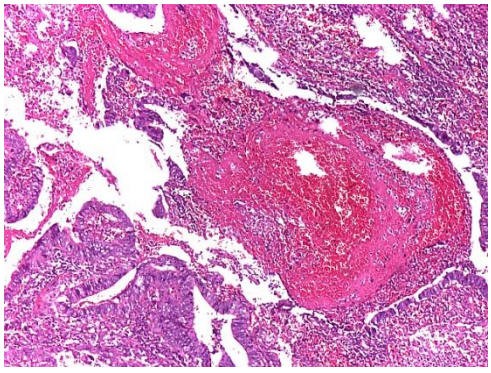

Fig. 3. Infiltration of the uterus, HE, x 4

The interdisciplinary meeting between surgeon, oncologist and pneumologist recommended anti TB treatment and reassessing the patient on regular basis. After one year when the patient completed the full course of anti-tubercular drugs, a thorough work-up was performed. Colonoscopy, CT of the thorax, abdomen, pelvis showed no signs of recurrence while tumoral marker CEA (1,62 ng/ml – n<3,4) and QFT (Quantiferon-TB Gold) test were within normal range.

DISCUSSION

Since the initial mentioning almost 200 years ago by Bayle, association of tuberculosis and carcinoma is well documented in

lungs, skin and larynx (1). However, the coexistence of carcinoma and tuberculosis is rare, especially when located on the same site on the colon. Less than 70 cases are reported in the literature and to our knowledge this is the first to be mentioned in Romania. In an extensive review, Falagas and col established three different types of association between malignancy and TB: (i) the development of cancer on a background of a previous tuberculous infection; (ii) the concurrent existence of TB and malignancy in the same patient(s) or clinical specimen(s); and (iii) the diagnostic challenges due to multi-faceted presentations of these two disorders (2).Experimental research found that *Mycobacterium tuberculosis* can induce DNA damage and increased ant apoptotic activity, which along with prolonged chronic inflammation may facilitate carcinogenesis (3-7).

As demonstrated that pulmonary scarring of TB etiology may generate lung cancers, chronic inflammatory mucosal changes from GERD and H. pylori gastritis are initiating a sequence of metaplasia and dysplasia results in neoplastic change. It is also universally accepted that severe weight loss or malnutrition related to an advanced neoplastic disease disturbs host immunity and increase susceptibility to activate tubercular infection, possibly by tumor peptides or antigens. On the other hand, according to some Indian authors, the association of carcinoma and tuberculosis is coincidental, the argument being that compared to the high incidence of abdominal tuberculosis in India, the cases of coexisting tuberculosis and carcinoma are very few (8,9).

A particular aspect of the case we report is the association with genital tuberculosis and a question to be asked is if TB lesions originated from the uterus or fallopian tube and subsequently involved the sigmoid or vice versa. Genital TB is almost always secondary to TB elsewhere in the body and the mode of spread is usually hematogenous or lymphatic and occasionally occurs by way of direct contiguity with an intraabdominal or peritoneal focus (10). Although only one tube appears infected, in more than 90% of patients with genital TB, the tubes are involved bilaterally.

CONCLUSIONS

In our study, although digestive tuberculosis is included in differential diagnosis for those patients presenting abdominal pain or obstructive digestive symptoms in endemic regions, in this case the absence of TB infection criteria and positive endoscopic biopsy for colonic adenocarcinoma did not allow a complete pre- or perioperative diagnosis.

NEWS

THE EFFECTS OF CHLORHEXIDINE AND SODIUM HYPOCHLORITE ON THE SETTING TIME OF CALCIUM-ENRICHED MIXTURE CEMENT

The aim of a study realized by a group of Iranian researchers was to evaluate whether adding 2% chlorhexidine and 2.6% sodium hypochlorite to calcium-enriched mixture cement would affect its setting time or not. The setting time of calcium-enriched mixture cement was evaluated in three groups (n=9) as follows: group 1; calcium-enriched mixture cement, group 2; calcium-enriched mixture cement+2% chlorhexidine and group 3; calcium-enriched mixture cement+2.6% sodium hypochlorite. Then the mean values of setting time were calculated and the Kolmogorov-Smirnov test was used to evaluate the normal distribution of data. The Kruskal-Wallis and Mann-Whitney U tests were used for statistical analysis. Statistical significance was set at 0.05. The obtained data show that the mean setting time for groups 1, 2 and 3 were 105, 120 and 220 min, respectively. There was a significant increase in the duration of setting time in group 3 (sodium hypochlorite) in comparison with the two other groups ($P<0.05$). In conclusion, the researchers showed that the sodium hypochlorite significantly increase the setting time of calcium-enriched mixture cement, whereas chlorhexidine did not alter the setting time (Frough Reyhani M, Ghasemi N, Shakouie S, Rahimi S, Salem Milani A, Ranjbar B. Effects of Chlorhexidine and Sodium Hypochlorite on the Setting Time of Calcium-Enriched Mixture Cement. *Iran Endod J.* 2015;10(3):162-164).

AXIAL MODIFICATIONS OF PERMANENT LOWER MOLARS AFTER PREMATURE LOSSES OF TEMPORARY MOLARS

AXIAL MODIFICATIONS OF PERMANENT LOWER MOLARS AFTER PREMATURE LOSSES OF TEMPORARY MOLARS (Abstract): **Aim**: The aim of our study was to determine the impact of premature loss of temporary lower molars upon the longitudinal axis of the first and second permanent molars. **Material and Methods:** The study groups included 61 patients, 6 -9 year olds with premature loss of primary molars and a control group of 24 patients with intact temporary teeth. We evaluated the angle between longitudinal axis of first and second lower permanent molars and occlusal plane. **Results.** It was observed that premature loss of lower second deciduous molar modifies more the vertical axis of first and second permanent molars than the premature loss of first lower primary molar. Reducing space occurs mainly through mesial inclination of molars that separates the edentulous breach. Temporary loss of both lower first molars on the same quadrant causes an accelerated eruption of both premolars increasing the prevalence of eruption sequence: "4-5-3-7".**Conclusions:** The preservation of the occlusal morpho-functional complex using space maintainers mainly when the premature loss of the second primary molars occurs is the best interceptive treatment option. **Keywords:** PREMATURE LOSS, AXIAL MODIFICATION, PERMANENT LOWER MOLARS, DENTAL CARIES, TEMPORARY TEETH.

The first one who debated upon the subject of premature loss of temporary teeth were *Hutchinson* and *Davenport* as early as the 1880s (1,2). The concept was defined as the exfoliation of deciduous teeth on the arch with more than 12 months prior to the normal eruption period of permanent teeth, exceeding the limits of normal variability of temporary teeth exfoliation sequences (3).

The most frequent causes that trigger the premature loss of temporary teeth are: untreated complicated dental cavities, traumatisms and premature root resorption.

The premature loss of temporary teeth, as a consequence of untreated dental cavity of temporary teeth may lead to serious tridimensional dental, dento-dental, dento-alveolar, occlusal and variably skeletal lesions. Thus, we control the migration of permanent teeth during intra-maxillary or oral eruption, the consequence being dento-alveolar incongruence. There may also appear super-eruptions of antagonist teeth, arch narrowing, reverse toothing, premature contacts and occlusal interferences (4).

Studies have shown that the premature

loss of temporary molars I mainly determines the distal migration of temporary canines. In this case, mesial displacement of permanent molars or their version cannot occur (5). Greater effects appear at the moment of the premature loss of second temporary molars, as they serve as a guide for the eruption of the permanent molar (6). The premature loss of second temporary molars – mainly mandibular - determines a shrinking of the arch length due to mesial inclination of permanent molars, compromising the „lee-way space" by affecting the posterior support area (7). The radiologic exam is mandatory for these patients. Although the cone beam computed tomography (CBCT) has progressively become a radiological method or reference in the oro-maxillo-facial sphere, the orthopantomography still represents a routine exam for children under 12 and not only. It thus represents a simple and economical way that uses a low radiation dose in comparison with the CBCT and allows a rapid quantitative and qualitative analysis both of the bone and the dental structures, allowing at the same time the quantification of the inclination degree of permanent molars in the context of the premature loss of temporary molars.

The main purpose of this study is to determine the impact of premature loss of mandibular temporary molars on the longitudinal axis of the permanent molars. A secondary objective is to verify whether there appear important modifications in the eruption sequence of the successors and the way the axis of the permanent molars is influenced.

MATERIAL AND METHODS

The study included 85 orthopantomographies of subjects aged 6 to 9 who reported to the Clinic of Pediatric Dentistry, Iasi. Out of these, 61 (71.8%) patients showed a premature loss of a lower temporary molar (study group) and 24 (28.2%) had intact dentition (control group). The study group was re-divided in all possible subgroups depending on the premature unilateral or bilateral loss of temporary molars. The precondition for the selection of subjects was that the incisors and permanent molars were intact. All patients received the required treatment and their written, informed and motivated approval was obtained.

All orthopantomographies were made at a single radiologic center by the same experienced technician in ideal conditions, using the radiologic device *PaX-Uni3D(Vatech)*®**.** At the moment of the orthopantomography the patients needed to have relaxed lips, a correct position of the head in relation to the chin support and the Frankfort plane needed to be parallel with the horizontal plane. Low quality, improper films or those with artifacts were excluded from the study from the beginning and the valid ones were saved digitally. Measurements were made by a single examiner using the *Easy Dent 4 Viewer*® software.

The orthopantomographies were processed by tracing the following structures (fig. 1):

-*the occlusion plane* – tangent line to vestibular cuspids of temporary molars/premolars and disto-vestibular cusp of lower right/left permanent molar;

-*the axis of primary permanent molar (M1)* – the line passing through the center of the crown and the center of radicular bifurcation;

-*the eruption axis of the second permanent molar (M2)* – the line passing through the middle of the crown and the center of the starting point of the radicular bifurcation.

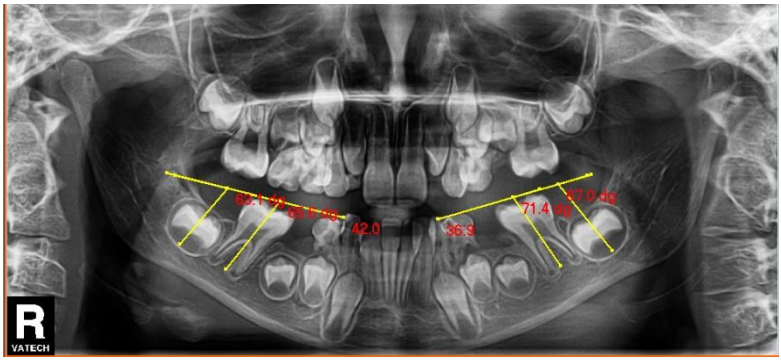

Fig. 1. Orthopantomographic aspect of premature loss of temporary molars

We thus evaluated the angle formed between the longitudinal axis of the first and second permanent molar and the occlusal plane in both lower quadrants. The software used for the data analysis was Statistical Package for the Social Sciences (version 20.0; SPSS, Chicago, III). We calculated the frequency and descriptive parameters (mean value, standard error, standard deviation, the minimum and maximum values) for each group. We used the *t-student test* to compare each group with the control group. The *t-pairs test* was used to compare the first permanent lower molars (M1) axes with second permanent lower molar (M2) axes of the two quadrants. The error limits used in the statistic interpretation are of 5% and the reliability range was of 95% .

In order to identify the possible errors during measurements we selected 25 radiographies. Measurements were repeated for the same radiographies and the *t-paired test* was used for the first and second measurement. No statistically significant difference was identified between the two measurements ($p>0.05$).

RESULTS

Out of the total 85 orthopantomographies analyzed, 45 (53%) patients were males (with an age average of 7.29) and 40 (47%) patients were females (average age 7.38). As far as the age distribution of subjects is concerned, there is a prevalence of patients aged 7 to 8 with an average age of 7.33.

In our study a total of 75 lower temporary molars were lost prematurely due to untreated dental cavities. The cumulated frequency of first temporary molar (m1t) and second temporary molar (m2t) losses shows a value of m1t close to m2t (37 (49.5%) for m1t and 38 (50.5%) of m2t).

From the point of view of angulation, the mesial-version mean for the control group of lower permanent M1 is of 80.38 ° (variation 69°-87°) and for lower permanent M2 of 69.74 ° (variation 50°-84°).

By analyzing the influence of *unilateral premature loss of lower temporary molars* on the inclination of permanent molar we may notice that the loss of lower m1t has very little influence on the axis of lower permanent molars (mean inclination of 80.078^{o}, with a variation between 73° and 85.4^{o} for M1 respectively a mean inclination of 65.47^{o} with a variation between 50^{0} and 81.50^{0} for M2). The loss of lower m2t determines an accentuated mesial-version of permanent molars (angular mean value of 77.29 ^{o} with a variation between 65.40^{o} and 85.50^{o} for permanent M1 and

respectively a mean value of 64.24° with a variation between 30° and 83° for permanent M2) . In case of loss both of m1t and of m2t, the angle between the longitudinal axis and the occlusal plane will increase close to the values of the control group up to mean angular values of 79.275° for M1 and of 68. 75 ° for M2 (fig. 2).

	control group	m1t loss	m2t loss	m1t+m2t loss
lower M1	80,38	80,07	77,29	79,37
lower M2	69,74	65,47	64,24	68,75

Fig. 2. Influence of unilateral premature loss of lower temporary molars on the inclination of permanent molars

The influence of *bilateral premature loss of lower temporary molars* on the inclination of permanent molars determines a mesial version of permanent molars in cases of bilateral loss of m2t (mean angular values being of 72.25° for M1 and of 60.91° for M2). Bilateral loss of both m1t and m2t influences positively the axis of permanent molars, determining in these cases a slight overhang towards the distal (mean angular values being of 81.15° for M1 and of 74.75° for M2) (fig.3).

	control group	m1t_left + m1t_right loss	m2t_left + m2t_right loss	m2t_left + m1t_left + m2t_right + m1t_right loss
Lower M1 right	79,48	77,68	70,00	79,00
Lower M2 right	69,93	68,15	62,45	78,50
Lower M1 left	81,05	80,95	74,50	83,30
Lower M2 left	67,58	73,33	59,38	71,00
Lower M1	80,38	79,31	72,25	81,15
Lower M2	69,74	70,74	60,91	74,75

Fig. 3. Influence of bilateral premature loss of lower temporary molars on the inclination of permanent molars

Using the *t-test* we compared the axes of permanent molars, in the case of reunited global groups with premature loss of lower m1t, of lower m2t and of lower m1t+m2t, namely with the axes of permanent molars on the same side of the control group. The only statistically relevant situation is the loss of lower m2t which influences both permanent M1 axis and the permanent M2 axis (tab. I).

TABLE I

Results of the comparison between the group with premature loss of m2t and the control group

The correlative analysis between M1 axis and M2 axis in the two quadrants was made by comparison to the control group, using the t test for pairs (*t-pairs*). In both cases there is a moderate correlation, but statistically significant between the M1 and M2 axes (axis right M1 & axis right M2, r=0.321, p=0.01; axis left M1 & axis left M2, r=0.510, p=0.000).

DISCUSSIONS

The premature loss of temporary molars has as a main consequence the reduction of the space requires for the eruption of premolars and for the correction of small frontal dento-alveolar incongruence which is normally accomplished due to the leeway-space (8). The greatest amount of space lost is due to the inclination of permanent molars towards the mesial. This inclination depends mainly on the dental age at the moment of the extraction but also on the sequence/periodicity of eruption (9-11).

Based on the analysis using the software we could observe with higher accuracy the angle formed by the longitudinal axis of the permanent molars with the occlusal plane and we could thus estimate a mean value, a minimum, maximum value and a standard deviation for the control group. A similar study which was conducted using an older technique, namely by tracing the teeth images and structures on tracing paper using a black pencil and the measurement of angles with the protractor,

considers that, for instance, the correct position of lower molar 1 is at an angle that ranges from $+80^o$ -$+100^o$ (12). The values we obtained for the lower M1 are similar with those in the previous study: the mean value being of $+80.38^o$ with a variation between $+69^o$-$+87^o$. These aspects are relevant from the point of view of the inter-relation between the moment of premature loss of m2t and the moment of initiation of eruption of the first permanent molar. The context of premature loss of second temporary molar occurred after the initiation of clinical eruption of the first permanent molar.

Many longitudinal studies for a period from 2 to 8 months on children aged 6 to 9 with *premature loss of the first lower temporary molar* concluded that the shrinking of the mesial space from the second molar is due mainly to the distal displacement of the temporary canine and less to the migration or inclination of permanent molars (13-16). These results are also confirmed by us, since the axes of the lower permanent molars were very little influenced after the loss of first temporary molars, being comparative with the values obtained for the control group. Thus, the mean angular value for lower M1 at the control group was of 80.38^o while in case of m1t loss the mean value was of 80.07^o, and for lower M2 at the control group the mean angular value was of 69.74^o as compared to the mean angular value in case of m1t loss of 65.45^o**.**

Many studies (9-11,16) showed that the *premature loss of second temporary molars* determines a greater loss of leeway-space than in the case of first temporary molar, due both to the bigger difference in the mesio-distal diameter and to the fact that the first and second permanent molar lose the contact point and follows the trend of all teeth to lean mesially. This is also proved by our study by the much lower angular mean values for permanent mandibular molars in case of premature loss of the second mandibular temporary molar as compared to the mean angular values from the control group.

As a matter of fact, the only instance in our study which is statistically significant is the loss of lower m2t which influences the axis of both lower permanent molars, a logical consequence if we take into consideration the dynamic particularization of the alveolar and maxillary skeletal and mandibular growth and development on the age groups studied.

Another interesting aspect to analyze is the *loss of both lower temporary molars* on the same quadrant. A study conducted by Leroy R. *et al* (17) in 2009, showed that at the moment of cavity deterioration of both lower temporary molars and their loss subsequent to the cavity damage, the ideal eruption sequence „3-4-5-7" is reversed, increasing the prevalence of the eruption sequence „4-3-5-7", „4-3-7-5" and „4-5-3-7". Thus there occurs an accelerated eruption of both premolars. This is also confirmed by us in the present study through the increase of the mean angular values between the longitudinal axis of the permanent molars and the occlusal plane close to the mean angular values of the control group, leading to their distal overhang.

The moderate correlation between the axes of first and second molars in the same quadrant suggests the fact that any molar premature loss may have an impact on the entire dento-maxillary apparatus and may have later repercussions in the development of dento-maxillary anomalies.

The theme studied by us requires further complex clinico-radiological studies

with a powerful analytical-statistical approach with a higher number of subjects, ecological repartition on genders and age stages and by using the advanced measurement techniques of CBCT type.

CONCLUSIONS

Our study proves one more time the problematic of the premature loss of lower second temporary molar, leading to a necessity to conduct more studies in this field. Its pathology fails to be limited in an intra-arch context due to the extrusion potential of second maxillary temporary molar which may generate premature contacts, occlusal interferences and may lead to the Thielemann effect on the long term (diagonal syndrome) affecting the opposite articulation. The modification of the eruption sequence following the premature loss of temporary molars is a phenomenon which needs consideration, especially when an interceptive treatment is adopted, with the preservation of the occlusal morpho-functional complex using space maintainers.

LITERATURE REVIEW CONCERNING THE LOCAL DRUG DELIVERY SYSTEMS IN THE TREATMENT OF PERIODONTITIS

In periodontitis, in order to complement non-surgical therapy, there are multiple options of antimicrobials (metronidazole, chlorhexidine, minocycline, doxycycline, tetracycline), which can be locally delivered into the mucosa. These antimicrobials are used in periodontal pockets and can inhibit or eliminate periodonto-pathogenic micro-organisms as well as modulate the inflammatory response of tissues. Currently, limited data are available regarding the relationship between effect, efficacy and clinical status of the periodontium. A review realized by o group of researchers aimed to evaluate the effect and the efficacy of different types of local drug delivery systems in clinical parameters of periodontology. Researched papers using MEDLINE via PubMed, and LILACS databases related to five types of local drug delivery systems (chlorhexidine gluconate, doxycycline hyclate, metronidazole gel, minocycline ointment and tetracycline fibers) were reviewed aiming to address the mechanism of action and the evidence of clinical effectiveness of adjunctive use of these antimicrobials following surgical and/or non-surgical therapies. Inclusion criteria defined that articles must be randomized controlled trials performed in humans and published between 1996 and 2014. The adjunctive use of local drug delivery systems with controlled release properties may provide a defined, but limited, beneficial response on periodontal pockets. Local drug delivery as an active treatment or maintenance therapy depends on clinical findings, responses to treatment described in the literature, desired clinical outcomes, and patients' dental and medical histories, including their past usage of antimicrobials (Da Rocha HA, Silva CF, Santiago FL, Martins LG, Dias PC, De Magalhães D. Local Drug Delivery Systems in the Treatment of Periodontitis: A Literature Review. *J Int Acad Periodontol.* 2015; 17 (3) : 82-90).

OPTIMIZATION OF THE PREPARATION OF KOLLIDON® SR-BASED AMIODARONE HYDROCHLORIDE TABLETS WITH SUSTAINED RELEASE (Abstract): **Aim:** The formulation of sustained release tablets of AMD·HCl using KOLLIDON® SR as matrix-forming agent. Chitosan, a natural polysaccharide with superior hydrating and absorbing properties was used in the formulation stage to optimize the release characteristics of those matrix tablets. **Material and methods**: Nine formulations of sustained release matrix tablets of AMD·HCl (200 mg/tablet) were prepared through direct compression. The concentrations of matrix forming agents were included as independent variables of a type 2^3 mixed factorial plan in order to develop formulations of AMD·HCl with optimal release characteristics. The dependent variables of that plan were the amount of AMD released from the tablets studied by using *in vitro* dissolution testing. The test was carried out in the paddle apparatus II for 12 hours in two pH media that were relevant to oral delivery: 2 hours at pH 1.2 and 10 hours at pH 6.8. The released AMD·HCl was quantitatively determined through a validated HPLC method. **Results:** The increase in KOL concentration leads to a decrease in AMD release rate at both pH values. The use of CHT resulted in a decrease of AMD release only at pH 6.8 in formulations with the lowest concentration of KOL. **Conclusions**: The retarding effect on the release of AMD·HCl in the tablets developed in this study was directly proportional to the KOL concentration in the formulation. **Keywords:** AMIODARONE HYDROCHLORIDE, TABLETS, EXTENDED RELEASE, KOLLIDON® SR, CHITOSAN.

Amiodarone hydrochloride (AMD·HCl) is one of the most prescribed therapeutic agents used in the treatment of cardiac tachyarrhythmia, due to its proven effectiveness. As AMD·HCl has limited oral bioavailability with many individual variations, the study on the inclusion of this active substance in oral delivery systems with sustained release characteristics might help optimize its biopharmaceutical characteristics.

Amiodarone (AMD) is an antiarrhythmic administered under the form of conventional release tablets (200 mg/tablet) for the treatment of ventricular and supraventricular rhythm disturbances, tachycardia in Wolff-

Parkinson-White syndrome, as well as in atrial fibrillation (1). AMD has a low oral bioavailability due primarily to its low solubility in water (0.2-0.7 mg/mL) (2).

MATERIAL AND METHODS

Materials: Amiodarone hydrochloride (Zhejiang Sanmen Hengkang Pharmaceutical Co. Ltd., China, purity 100.2 %), Kollidon® SR (KOL) and Chitosan practical grade (CHT) (BASF, Germany), Aerosil 200 (Degussa, Germany), and magnesium stearate (Union Derivan SA, Spain).

Preparation of matrix tablet: Nine AMD matrix tablets were formulated and prepared through direct compression method using a *Korsch EK0* tablet press (punch diameter of 9 mm, compression pressure of 8-10kN). To assess the influence of matrix-forming polymers on the release profile of AMD, a type 2^3 experimental plan (tab. I) was developed, in which the independent variables were marked as follows: X_1 - percentage of KOL (three values: 40, 50, 60), X_2 - percentage of CHT (three values: 3, 5, 7). The concentrations of these matrix forming agents were included as independent variables of a type 2^3 mixed factorial plan in order to investigate their influence on *in vitro* release of AMD.

TABLE I

The matrix of the experimental plan

Nº	X_1 (KOL)	X_2 (CHT)
1	40	3
2	40	5
3	40	7
4	50	3
5	50	5
6	50	7
7	60	3
8	60	5
9	60	7

In vitro dissolution studies: In vitro release studies were performed according to the specifications in the monograph "Dissolution test for solid dosage forms" European Pharmacopoeia 8th Edition (3), following this experimental protocol: *dissolution medium*: pH 1.2 solution (0.1N HCl) for the first 2 hours (as simulated gastric fluids) and pH 6.8 solution (phosphate buffer solution) for the next 10 hours (as simulated intestinal fluids); *Apparatus 2 (with paddles) SR 8 Plus Series* (AB & L Jasco); *bath temperature*: 37±0.5ºC; *rotation speed*: 50 rpm; the sampling interval was set at one hour during the 12 hours test (at each sampling hour, 7 mL of sample were replaced by the same volume of medium) (4-6).

AMD was quantitatively determined by a validated HPLC method. The dependent variables of the experimental plan were the amount of AMD released at each sampling hour, as follows: Y_1 (% of AMD released after 1 hour), Y_2 (% of AMD released after 2 hours), Y_3 (% of AMD released after 3 hours), Y_4 (% of AMD released after 4 hours), Y_5 (% of AMD released after 6 hours), Y_6 (% of AMD released after 8 hours) Y_7 (% of AMD released after 10 hours) Y_8 (% of AMD released after 12 hours). The data were statistically analysed and interpreted using the *Matlab 7.9.* software (7-10).

RESULTS AND DISCUSSION

These results show the major role played by KOL in the release of AMD from matrix tablet formulations. The amount of released AMD varied inversely with the percentage of KOL in the formulas for all formulations (regardless of the variable X_2). A particular behaviour was observed in F1 formula which released 63.63% of

the amount of AMD within the very first 2 hours of the dissolution test, in a medium of simulated gastric fluid. Another interesting feature of that formulation was that AMD was released almost entirely (released AMD = 99.77 %) at the end of the 12 hours test (fig. 1).

The influence of KOL was also confirmed by the results of quadratic regression analysis (tab. II, fig. 2,3.).

CONCLUSIONS

During our study we observed that the X_2 variable (% CHT) initially had a positive effect on the release of AMD, but later it had a retarding effect. That influence of CHT at pH 1.2 could be explained by its solubility in that medium that promoted matrix hydration and consequently stimulated the release of the active ingredient. Following that moment (Y_1), the retarding effect on AMD release exerted by CHT was stronger than the effect produced by KOL (tab. II). The interactions between the two variables were positive, except for Y_1, but they could be considered negligible. We noticed a retarding effect on AMD release from the obtained formulations and that was directly proportional to the KOL concentration. Initially, CHT increased the release of AMD, but later we concluded that it inhibited the release process, and the interactions between the two polymers had a negligible effect on the release of the active ingredient.

NR4A1-ACTIVATED RECEPTORS ASSOCIATED WITH Ca^{2+} CYTOSOLIC INCREASE IS NOT INDUCING AUGMENTED APOPTOSIS OF PRO-B CELLS (Abstract) **Background**: The involvement of NR4A1 orphan receptors activation in pre-lymphocytes, pro-lymphocytes and lymphocytes apoptosis is controversial, also when related to calcium fluxes. **Aim**: The goal of our study was represented by the characterization of NR4A1 activation-induced effects on pro-B cells apoptosis in the presence of ionomycin, a calcium overloading inducer. **Methods**: All cells batches were evaluated under contrast-phase microscopy, using an Eclipse TE-300 Nikon microscope with a 40x objective. The apoptotic cells number was expressed as a percentage of the total number of cells, taking into account their morphological appearance. **Results**: The treatment of pro-B cells with 5 μM ionomycin and 1 mM Ca^{2+} in culture medium for 24 hours induced a modest, but significant apoptosis as compared to control series, evidenced by morphological appearance. On the other side, the pro-B cells treated with 50 μM Cytosporone B for 24 hours, together with 5 μM ionomycin and 1 mM Ca^{2+} show a reduced grade of apoptosis as compared to solely ionomycin and calcium series. **Conclusions**: Thus, NR4A1 orphan receptor activation might reduce the apoptotic effects of calcium overload in pro-B cells, an intriguing effect which might be further researched.
Keywords: PRO-B CELLS, NR4A1 RECEPTOR, APOPTOSIS, IONOMYCIN.

Nuclear receptors are members of a large super family of evolutionarily related transcription factors that control a plethora of biological processes. Nuclear receptors orchestrate complex events such as development, organ homeostasis, metabolism, immune function, and reproduction. Approximately one-half of the 48 human nuclear receptors have been shown to act as ligand-regulated transcription factors and respond directly to a large variety of endogenous hormones and metabolites that are generally hydrophobic and small in size (e.g., retinoic acid or estradiol). The second half of the nuclear receptors family comprises the so-called orphan receptors, for

which regulatory ligands are still unknown or may not exist despite the presence of a C-terminal ligand-binding domain, which is the hallmark of all nuclear receptors (1).

Three members of the NR4A orphan nuclear hormone receptor subfamily (NR4A1, NR4A2, and NR4A3) belong to the steroid nuclear hormone receptor super family. They share similar structural features and have no known natural ligand. They constitute immediate early genes that are induced by serum, growth factors and receptor engagement and are thus implicated in cell mitogenic responses. They have been shown to play a role in complex pathways of cell survival and apoptosis. Recent studies have also suggested an important role of these receptors in cell transformation and tumorigenicity via both their anti-apoptotic and pro-apoptotic functions (2).

Thus, the orphan nuclear receptor NR4A1/Nur77/TR3/NGFIB acts primarily as a transcription factor to regulate the expression of multiple genes. However, increasing research attention has recently been given to non-genomic activities of NR4A1. To be also mentioned, the role of NR4A1 in apoptosis is controversial (3).

The induction of thymocyte apoptosis through the NR4A1-mediated intrinsic pathway can be of physiological importance in the clonal deletion of autoreactive thymocytes during negative selection in the thymus and/or in thymocytes undergoing oncogenic transformation. Ionomycin treatment induces endogenous NR4A1 expression as well as apoptosis and cytochrome c release in thymocytes (4).

The goal of our study was represented by the characterization of NR4A1 activation-induced effects on pro-B cells apoptosis in the presence of ionomycin, a calcium overloading inducer.

MATERIALS AND METHODS

An IL-3-dependent mouse pro-B cell line was maintained in RPMI 1640 (Sigma-Aldrich) medium supplemented with 2 mM L-glutamine, 100 U/ml penicillin, 100 μg/ml streptomycin, 10% heat-inactivated fetal bovine serum and recombined murine IL-3 (Sigma-Aldrich), in an atmosphere with 5% CO_2 and at 37°C (5, 6).

Cells were grown at a density of around $5x10^5$ per ml before experiments, each one being performed using $1x10^6$ cells/ml. For some experiments (in triplicate) pro-B cells were treated with 5 μM ionomycin and 1 mM Ca^{2+} in culture medium for 24 hours. To test the NR4A1 receptor activation we administered 50 μM Cytosporone B for 24 hours, together with 5 μM ionomycin and 1 mM Ca^{2+}. The control Ba/F3 cells received no treatment for 24 hours (stated as normal around 12-15% apoptotic series). The second control series was represented by the administration for 24 hours of 1 μM Valinomycin (stated as almost 90% apoptotic series).

All batches were evaluated under contrast-phase microscopy, using an Eclipse TE-300 Nikon microscope with a 40x objective. The apoptotic cells number was expressed as a percentage of the total number of cells, taking into account their morphological appearance.

The statistical significance of test results was highlighted using the Variance One-Way ANOVA, All Pairwise Multiple Comparison Procedures (Holm-Sidak method) and the results were expressed as mean±S.E.M (n=3). Values of $p<0.05$ were considered statistically significant always.

RESULTS

For the pro-B cells, 87.53±3.65% are associating normal morphological appearance as shown in Fig. 1 (control series,

triplicate experiment).

The apoptosis was evident when we treated the cells with 1 μM Valinomycin for 24 hours (that means 9.64±1.31% normal morphological appearance, n=3), as Fig. 2 shows.

The treatment of pro-B cells with 5 μM ionomycin and 1 mM Ca^{2+} in culture medium for 24 hours (Fig. 3) induced a modest, but significant apoptosis as compared to control series (68.91±3.72% normal morphological appearance, n=3, $p<0.05$).

For some experiments (in triplicate) pro-B cells were treated with 50 μM Cytosporone B for 24 hours, together with 5 μM ionomycin and 1 mM Ca^{2+} (Fig. 4). In this particular case, 81.57±3.48% of the pro-B cells are associating normal morphological appearance, suggesting a reduced apoptosis (n=3, $p>0.05$ as compared to control series). Treatment with 50 μM Cytosporone B alone induced no significant apoptosis as compared to control series (personal observation, data not shown).

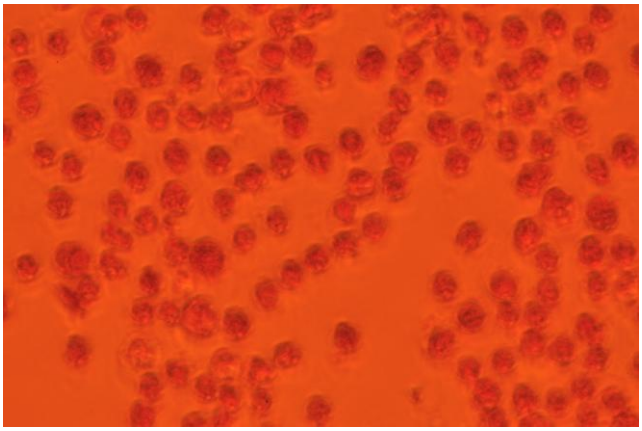

Fig. 1. Representative normal morphological appearance for murine pro-B cells (contrast phase, 40x).

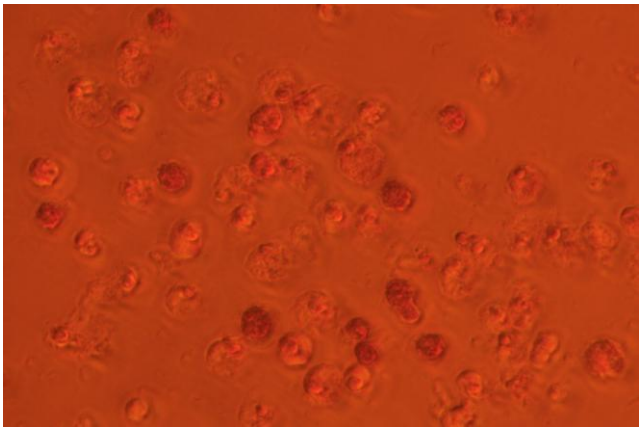

Fig. 2. Valinomycin (1 μM) is inducing massive apoptosis of pro-B cells after 24 hours treatment (contrast phase, 40x).

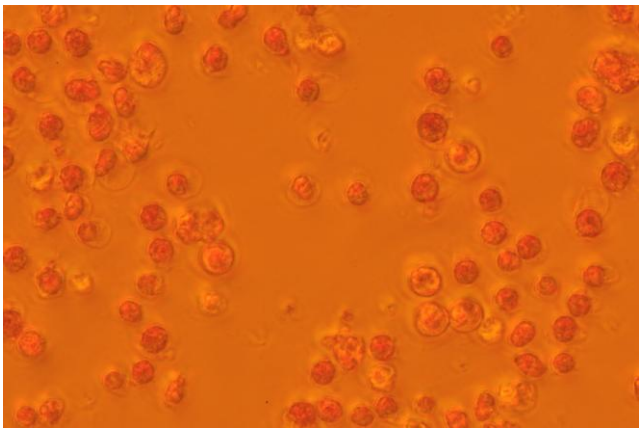

Fig. 3. The treatment of pro-B cells with 5 μM ionomycin and 1 mM Ca^{2+} in culture medium for 24 hours induced a modest, but significant apoptosis (contrast phase, 40x).

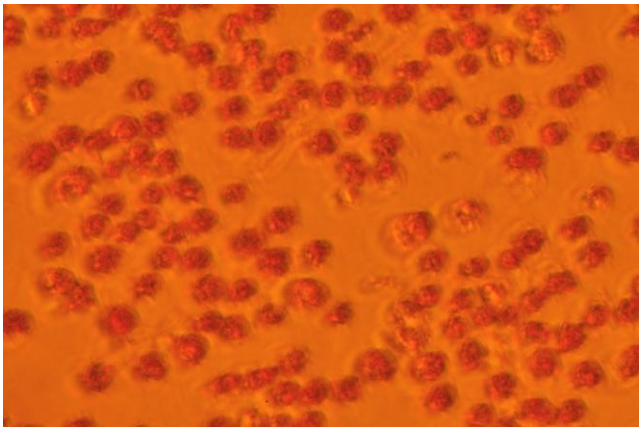

Fig. 4. For some experiments, the pro-B cells treated with 50 μM Cytosporone B for 24 hours, together with 5 μM ionomycin and 1 mM Ca^{2+} are associating reduced apoptosis (contrast phase, 40x).

DISCUSSION

Apoptosis, one of the best-studied forms of programmed cell death processes, plays an important role during the development and life-cycle of most multicellular organisms. This program might consist of the successive activation of unique apoptosis-specific genes, which are solely involved in the regulation of the programmed cell death. However, more and more evidence is accumulating that novel genes are not activated or induced during apoptosis, but rather many well-known genes previously described for their roles in processes such as proliferation and differentiation and belonging, for example, to the protein families of immediate-early genes and transcription factors become activated. The death-specific feature is achieved thereby by the extent, combination, and specific timing of gene expression (7).

The role of calcium elevations in apop-

totic and necrotic cell death has been a focus of research in recent years. Evidence has been presented that calcium oscillations can effectively trigger apoptosis under certain conditions and that dysregulation of calcium signaling is a common cause of cell death. These effects are regularly mediated through calcium signal propagation to the mitochondria and the ensuing mitochondrial membrane permeabilization and release of pro-apoptotic factors from mitochondria to the cytoplasm (8).

In HepG2 cells and primary hippocampal neurones in culture ionomycin, a well known neutral calcium ionophore, promoted the equilibration of Ca^{2+} gradients between cellular compartments, including endoplasmic reticulum, mitochondria and cytosol. Thus, $[Ca^{2+}]_c$ and $[Ca^{2+}]_m$ increased together and then recovered in parallel on removal of the ionophore (9).

Ionomycin caused some mitochondrial depolarization also in our previous experiments on pro-B cells, although this was low in degree (5).

Within the nuclear receptor family, Nur77 (also known as NGFI-B) distinguishes itself by its ability to bind a target sequence (the NBRE) as a monomer and by its role in T-cell receptor (TCR)-induced apoptosis in T cells (10).

Apoptosis accompanying negative selection is a central but poorly understood event in T cell development. The Nur77 nuclear steroid receptor and Bim, a proapoptotic BH3-only member of the Bcl-2 family, are two molecules implicated in this process. However, how they relate to each other and how Nur77 induces apoptosis remain unclear. In thymocytes, Nur77 has been shown to induce cell death through a transcriptional-dependent pathway, but in cancer cell lines, Nur77 was reported to induce apoptosis through conversion of Bcl-2 into a killer protein at the mitochondria. Whether this Nur77 transcriptional-independent pathway actually occurs in vivo remains controversial. Using an optimized fractionation protocol for thymocytes, here we report that stimulation of CD4(+)CD8(+) thymocytes results in translocation of Nur77 and its family member Nor-1 to the mitochondria, leading to their association with Bcl-2 and exposure of the Bcl-2 proapoptotic BH3 domain. In two T cell receptor transgenic models of negative selection, F5 and HY, a conformational change of the Bcl-2 molecule in the negatively selected T cell population was similarly observed. Thus, the Nur77 family and Bim pathways converge at mitochondria to mediate negative selection (11).

Defects in apoptosis mechanisms play important roles in malignancy and autoimmunity. Orphan nuclear receptor Nur77/TR3 has been demonstrated to bind antiapoptotic protein Bcl-2 and convert it from a cytoprotective to a cytodestructive protein, representing a phenotypic conversion mechanism. Of the 6 antiapoptotic human Bcl-2 family members, we found that Nur77/TR3 binds strongest to Bcl-B, showing selective reactivity with Bcl-B, Bcl-2, and Bfl-1 but not Bcl-X(L), Mcl-1, or Bcl-W. Nur77 converts the phenotype of Bcl-B from antiapoptotic to proapoptotic. Bcl-B is prominently expressed in plasma cells and multiple myeloma. Endogenous Bcl-B associates with endogenous Nur77 in RPMI 8226 myeloma cells, where RNA interference experiments demonstrated dependence on Bcl-B for Nur77-induced apoptosis. Furthermore, a Nur77-mimicking peptide killed RPMI 8226 myeloma cells through a Bcl-B-dependent mechanism. Because Bcl-B is abundantly expressed in plasma cells and some myelomas, these findings raise the possibility of

exploiting the Nur77/Bcl-B mechanism for apoptosis for eradication of autoimmune plasma cells or myeloma (12).

Human genes of polycomb group correlate with various hematological and epithelial cancers, identifying new mechanisms of malignant transformation and pave the wat for developing new cancer treatments and new diagnostic markers. B-cell-specific Moloney murine leukemia virus integration site 1 (Bmi-1) is a member of polycomb group, which participates in axial patterning, hematopoiesis, cell cycle regulation, and senescence, and represents a future target for treatment and diagnosis (13).

Nowadays cancer is still a major public health issue. Mortality by cancer is on the second place after the one caused by cardiovascular diseases. The high mortality and the increasing incidence of certain cancers justify a growing interest for the identification of new pharmacological agents efficient in cancer prevention and treatment (14).

CONCLUSIONS

In our study, the treatment of pro-B cells with ionomycin and Ca^{2+} in culture medium for 24 hours induced a modest, but significant apoptosis as compared to control series, evidenced by morphological appearance. On the other side, the pro-B cells treated with Cytosporone B for 24 hours, together with ionomycin and Ca^{2+}, show a reduced grade of apoptosis as compared to solely ionomycin and calcium series.

Thus, NR4A1 orphan receptor activation might reduce the apoptotic effects of calcium overload in pro-B cells, an intriguing effect.

RATES OF FORMAL DIAGNOSIS OF DEMENTIA IN PRIMARY CARE: THE EFFECT OF SCREENING

A timely diagnosis of dementia is considered of major importance to ensure adequate access to information, evidence-based treatment, care, and support for people with dementia. However, even in high-income countries with advanced medical care systems, 50% to 80% of all prevalent dementia cases are not formally diagnosed. The screening of older patients for cognitive impairment could be a method to improve the recognition of dementia. Previous studies have shown that screening for dementia in general practitioners' (GPs) practices did increase the diagnosis rates. Nevertheless, routine screening for dementia has been controversial and is not presently recommended in the dementia guidelines owing to the lack of evidence that patients benefit from it. In addition, patients with positive screening results often undergo no additional diagnostic assessment and do not receive specific treatment. For the benefit of patients, a positive screening outcome should initiate an adequate diagnostic assessment and, depending on the results, state of the art treatment and care. Furthermore, screening could result in potential harms. Older patients might avoid visiting their GP because they fear to be diagnosed with dementia. Also, false-positive screening results increase the probability for misdiagnosis, could result in unnecessary examinations and treatments, and might cause anxiety and depression in the affected subjects. Only 1.5% of the patients reported that they worried more about their health after the screening. Other surveys revealed that a clear majority of participants would prefer to be diagnosed early and expected to be properly informed about their diagnosis. Also, the proactive "dementia case finding scheme" was initiated by the government of the United Kingdom, aiming to increase the diagnosis rate of dementia and to improve dementia treatment and care on the population level. Thus, the present analysis revealed a strong effect of screening for dementia among primary care patients on the probability of receiving a formal diagnosis of dementia (Eichler T, Thyrian JR, Hertel J,l. et al. Rates of formal diagnosis of dementia in primary care: The effect of screening. Alzheimer's & Dementia: Diagnosis, Assessment & Disease Monitoring 2015; 1: 87–93).

BIOENERGETIC CHARACTERIZATION OF H9C2 CELLS USING THE EXTRACELLULAR FLUX ANALYZER (Abstract): **The aim** of the present work was to standardize the working methodology for assessing the bioenergetic profile of H9c2 cardiomyoblasts cells, with reference to the optimization of cell seeding number and the establishment of favorable concentrations for the classic modulators of mitochondrial respiratory function, in particular the one of a classical uncoupler, FCCP. **Material and methods:** The extracellular flux analyzer (XF, Seahorse Bioscience) is a novel high-throughput instrument able to monitor the metabolism of living cells by simultaneously measuring mitochondrial respiration and glycolysis. The *in vitro* platform will be further used to better understand the pathophysiology and the unrecognized side effects of drugs currently used in the therapy of major cardiovascular diseases. **Conclusions:** In the long run, characterization of novel pharmacological agents' effects on other cell lines, including tumoral ones, will be also considered. **Keywords:** EXTRACELLULAR FLUX ANALYZER, CARDIOMYOBLASTS, MITHOCONDRIAL RESPIRATION, GLYCOLYSIS

Assessing the bioenergetic profile of myocardium, the most metabolically active tissue, has become nowadays a highly investigated research field. Indeed, mitochondrial dysfunction is widely recognized as a central event responsible for the progression of the most non-communicable diseases.

In the past decade, a thorough insight into the subcellular pathophysiology of living cells and their changes in response to increased demands and environmental agents (1) with a particular interest for mitochondrial function/dysfunction has gained a lot of interest in the field of translational research (2-5). The Extracellular Flux Analyzer (XF, Seahorse Bioscience) represents a modern, automatic platform allowing the simultaneous measurement in real-time of the two major energy pathways: mitochondrial respiration and glycolysis (6). The 2 major parameters provided are: i) the Oxygen Consumption Rate (OCR) as indicator of mitochondrial respiration and the Extra-

cellular Acidification Rate (ECAR) as indicator of lactate release via glycolysis, respectively. By providing information regarding the oxygen-dependent and independent pathways for ATP generation, the XF analyzer allows a comprehensive characterization of cellular bioenergetic profile and, also interrogation of drug response and toxicity. With respect to the former issue, cells are metabolically perturbed via successive additions of compounds that modulate mitochondrial respiration (7). In order to perform a systematic characterization of the bioenergetic profile of H9c2 cell line, the present study was purported to (i) identify the effects of H9c2 cell seeding density on the basal and perturbed mitochondrial respiration and glycolysis; (ii) determine the concentration of a classical uncoupler, FCCP (carbonyl cyanide-p-trifluoromethoxyphenylhydrazone), that is responsible for the maximal bioenergetic response.

MATERIAL AND METHODS

Cell culture. H9c2 rat cardiomyoblast cell line (purchased from ECACC) was maintained in a humidified incubator gassed with 5% CO_2 at 37°C. Cells were grown in high-glucose (4.5g/l) Dulbecco's modified Eagle's Medium (DMEM) supplemented with 1 mM sodium pyruvate, 5 mM HEPES, 10% FBS, and penicillin-streptomycin (100 U/ml). Cells were seeded for 24 hours in Seahorse XF-24 cell culture plates at different densities: 10, 20, and 25 K cells/well, respectively.

Bioenergetic measurements. The experimental protocol for the characterization of the bioenergetic profile of H9c2 cells was adapted after Nicholls et al. (7). In the day of the experiment, DMEM was replaced by unbuffered XF Assay Media supplemented with 25 mM glucose. XF-24 cell plates were placed in XF Prep Station (37°C incubator without CO_2) for 60 minutes allowing pre-equilibration of the cells with the XF Assay Media. The oxygen consumption rate (OCR) and the extracellular acidification rate (ECAR) were simultaneously measured after the pneumatically sequential injections of 3 compounds that shift the energetic profile of the myoblasts: i) oligomycin (an ATP-synthase inhibitor, 1 μg/ml), ii) FCCP (a respiratory uncoupler, 1 and 3.0 μM), and iii) antimycin A (a complex III inhibitor, 5 μM) (7-9). Background correction wells (i.e., wells not seeded with cells) were used to normalize the data to background plate noise. Cells were randomized into 6 groups: 10 K/1 FCCP group (10 K cells/well injected with 1 μM FCCP), 10 K/3 FCCP group (10 K cells/well injected with 3 μM FCCP), 20 K/1 FCCP group (20 K cells/well injected with 1 μM FCCP), 20 K/3 FCCP group (20 K cells/well injected with 3 μM FCCP), 25 K/1 FCCP group (25 K cells/well injected with 1 μM FCCP), and 25 K/3 FCCP group (25 K cells/well injected with 3 μM FCCP). OCR was expressed in units of nmoles/minute/nr of cells and ECAR in mpH/minute/nr of cells.

The following OCR parameters were further calculated and analyzed (fig.1):

- Basal respiration: OCR measured before initializing the automated injections;
- ATP turnover: the amount of O_2 consumption used for ATP production;
- Proton leak: the amount O_2 used to maintain the proton gradient;
- Maximal respiration under conditions of uncoupled respiration;
- Reserve capacity: the difference between maximal and basal respiration (8, 10);
- Non-mitochondrial respiration: the

amount of O_2 consumption not due to mitochondrial processes.

OCR was corrected for oxygen flux due to instrumental background and non-mitochondrial respiration. The respiratory control ratio (RCR) was calculated as the ratio between the maximal respiration and the proton leak.

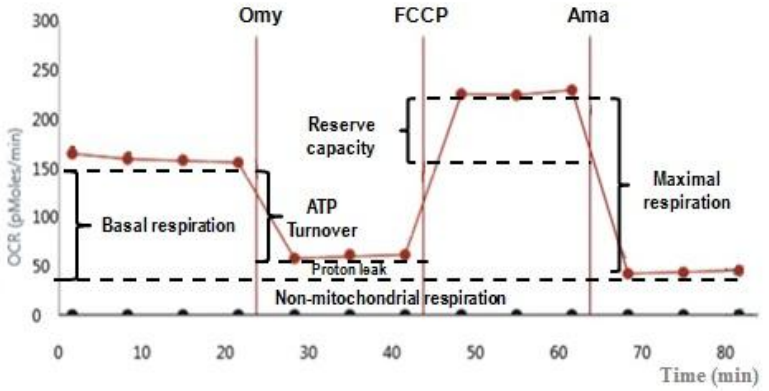

Fig. 1. OCR parameters in H9c2 cells: Basal respiration - OCR before injections; Proton leak - the difference in OCR after oligomycin (Omy) and antimycin A (Ama) injections; ATP turnover - the difference between basal respiration and proton leak; Maximal respiration - OCR after FCCP injection; Reserve capacity - the difference between maximal and basal respiration; Non-mitochondrial respiration - OCR after antimycin A injection. *Reagents.* All reagents and consumables were purchased from Sigma-Aldrich and Seahorse (Bioscience).

RESULTS AND DISCUSSION

We firstly characterized the cellular response to sequential injections. When oligomycin was injected, OCR suddenly decreased, because the proton channel of the Fo portion ATP synthase was blocked and the ATP synthesis via oxidative phosphorylation was inhibited; subsequently, the energy production shifted to glycolysis, which is reflected by an increase in ECAR. When FCCP was injected, OCR significantly increased as more O_2 was consumed to pump the excess protons back across the mitochondrial membrane, while ECAR increased due to cells attempt to maintain their energy balance by using glycolysis to generate ATP. Finally, when antimycin A was injected, OCR significantly decreased, since mitochondrial Complex III was inhibited and respiration was shut down; ECAR was maintained since cells shifted to a glycolytic state in order to maintain their energy balance (7, 8) (tab. I, fig. 2).

The first goal of this study was to identify the effects of H9c2 cell seeding density on the basal and perturbed OCR and ECAR. Firstly we observed that both OCR and ECAR values were sufficiently above the background noise and within the linear response range of the cells. In this experiment, we observed linear increases with OCR values as cell density increases, but when we reported OCR parameters to the number of cells, this observation was no longer valid. Still, the best RCR, the classical parameter for the mitochondrial qualita-

tive control (11), was obtained at 25 K cells/well. The ECAR data were less easily read, but still we noticed that ECAR also increased from 20 to 25 K cells/well.

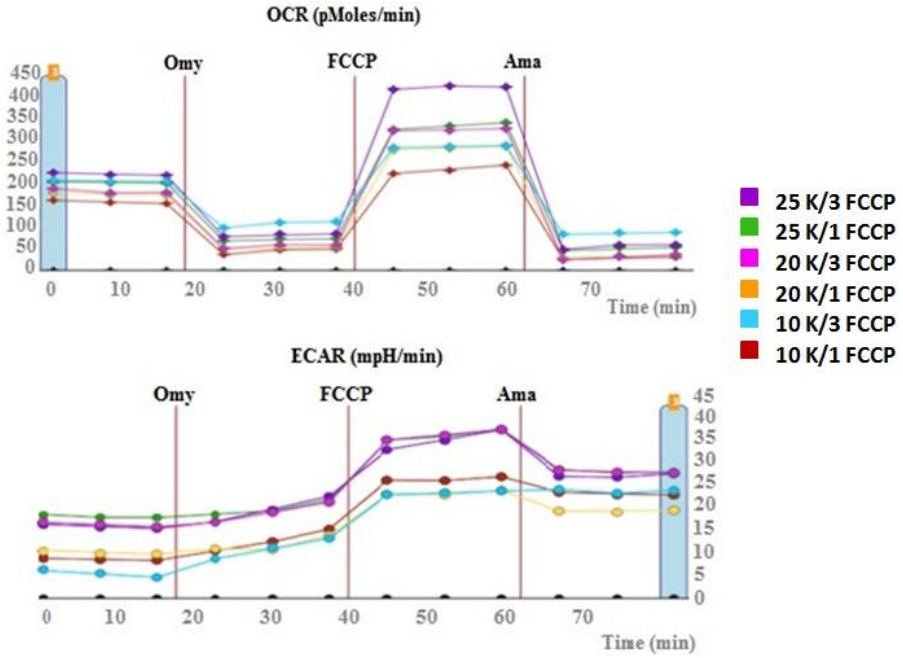

Fig. 2. OCR and ECAR evolution *vs.* time in the presence of pharmacological modulators.

TABLE I

OCR parameters and ECAR in H9c2 cardiomyoblasts

Cell groups	OCR (nmoles/min/nr cells)						ECAR (mpH/min/nr cells)
	Basal respiration	Proton leak	ATP turnover	Maximal respiration	Reserve capacity	RCR	
10K/1FCCP	12.13	5.44	6.7	20.42	8.3	3.7	1.3×10^{-3}
10K/3FCCP	13.53	3.8	9.72	18.83	5.3	4.9	1.6×10^{-3}
20K/1FCCP	6.7	1.7	5	8.94	2.3	5.3	0.8×10^{-3}
20K/3FCCP	7.2	1.8	5.38	11.52	4.34	6.4	1×10^{-3}
25K/1FCCP	4.8	1.33	3.47	9.91	5.12	7.5	0.85×10^{-3}
25K/3FCCP	6.25	1.51	4.73	12.56	6.31	8.3	1.3×10^{-3}

Data are expressed as mean values (n = 6-8/group)

Another goal of this experiment was to determine the concentration of FCCP responsible for the maximal OCR and ECAR responses, since high concentrations of FCCP may present an inhibitory effect (7-9). We noticed that OCR was maximal when FCCP was used in the higher concentration in groups 4 and 6, suggesting that cultured myoblasts present an increased reserve capacity, that is, an increased capacity to re-

spond to stress (8). Thus, after standardizing in a previous paper the methodology for high-resolution respirometry studies in permeabilized myocardial fibers we here provide for the first time in Romania a standardized protocol for the assessment of bioenergetic function of cardiomyoblasts (12).

CONCLUSIONS

We report here that the optimal bioenergetic profile of H9c2 cells was obtained at a density of 25,000 cells/well in the presence of 3 μM FCCP. These findings will be further used in experiments assessing the bioenergetic effects of different pharmacological agents on H9c2 cells, as well as on other cell lines (including tumoral ones), since this is one of the major applications of the XF analyzer besides the characterization of the changes in overall bioenergetics of the cells in response to stress and various insults.

THE EFFECTS OF PREGABALIN ON PSYCHO-MOTOR ABILITIES AND COGNITIVE PROCESSES IN MICE (Abstract): The purpose of our study was the experimental research on the effects of pregabalin in two behavioural models in mice. **Material and methods:** The experiment was carried out with white Swiss mice treated intraperitoneally as follows: Group I (Control): distilled water 0,1ml/10g body weight; Group II (PGB 10): 10mg/kbw pregabalin; Group III (PGB 20): 20mg/kbw pregabalin. The psychomotor abilities of pregabalin were tested on a LE-8811 Actimeter device (Panlab), in order to investigate both global motor behaviour and number of escape attempts during an eight-minute interval session. The exploration of memory processes performance was assessed using the Y-maze model, based on the natural tendency of mice to explore new environment. Data were analyzed using SPSS 13.0 for Windows software. The experimental protocols were implemented according the guidelines of "Grigore T. Popa" University Committee for Research and Ethical Issues. **Results:** The administration of pregabalin resulted in a dose-dependent reduction of mice horizontal and vertical movements, statistically significant compared to the Control group. The administration of both PGB10 and PGB20 induced no modifications of the spontaneous alternation percent; also, it did not influence the arm entries number compared to Control group in Y-maze test. **Conclusions:** The results reflect a significant dose-dependent diminution of number of escape attempts, exploratory and self-maintenance spontaneous behavior after pregabalin treatment, which could be correlated with an anxiolytic effect. Moreover, the study proved that pregabalin did not modify the animal cognitive processes performance or influence short-term memory of mice in the Y-maze test. **Keywords:** PREGABALIN, MICE, PSYCHO-MOTOR, Y-MAZE.

The (S-[+]-3-isobutylgaba) derivative pregabalin is a novel gamma-aminobutyric acid analogue, structurally related to the antiepileptic drug gabapentin, with a high efficacy as an adjunctive treatment for epilepsy and neuropathic pain (1).

It is a potent ligand for the alpha-2-delta subunit of P/Q type voltage-gated calcium channels that reduce synaptic release of neurotransmitters in the central nervous

system. Pregabalin-mediated reduction in calcium currents has also been proved to produce a significant inhibition of the release of glutamate and monoamine neurotransmitters involved in the modulation of anxiety pathways (2).

Pregabalin is structural related to the inhibitory neurotransmitter gamma aminobutyric acid (GABA), but lacks affinity on $GABA_A$, $GABA_B$, or benzodiazepine receptors. It does not influence the functionality of sodium channels or the activity of cyclooxygenase enzyme subtypes. It is also inactive on the opioid, serotonin and dopamine receptors (3).

This drug, with a high solubility and good permeability is rapidly and nearly completely absorbed after oral administration, without binding to serum proteins. The maximum plasma concentration is reached approximately after 1 hour. After single or multiple dose administration maximum plasma concentration and area under the curve concentration-time curve values are linearly augmented (4). The half-life time ranges from 5,5 to 6,7 hours depending on the administration route. Usually, the major way of excretion for pregabalin is urinary as unchanged drug, with a renal clearance of 73 ml/minute and an elimination half-life of about 6 hours. (5)

Some experimental researches are consistent with a mechanism that may entail reduction of abnormal neuronal excitability through reduced different neurotransmitters (glutamate, norepinephrine, substance P, calcitonin gene-related peptide) release (3, 4).

Pregabalin has been used to treat painful diabetic neuropathy, post-herpetic neuralgia, partial seizures, fibromyalgia, but also neuropathic cancer pain (6, 7, 8). It also has proven to be effective as a sleep modulating agent and an anxiolytic drug (9, 10).

The present study aims to investigate the effects of pregabalin on spontaneous behaviour and on spatial memory performances in mice.

MATERIAL AND METHODS

The experiment was carried out on white male Swiss mice (20-25g), distributed into 3 groups of 6 animals each treated intraperitoneally as follows: Group I (Control): distilled water 0,1ml /10 g body weight; Group II (PGB 10): pregabalin 10mg/kbw; Group III (PGB 20): pregabalin 20mg/kbw.

The animals were housed in groups of four in Plexiglas cages maintained on a 12 hours light/dark cycle in a temperature-controlled (22 ± 1°C) colony with access to water and food *ad libitum*, except during the experimental sessions. Before the beginning of the study, animals were allowed to adapt to the environment for one week. All experiments were carried out between 08:00 a.m. and 13:00 p.m.

Pregabalin (Mesochem Technology, China) was diluted in distilled water extemporaneously and injected intraperitoneally (i.p.) in a volume of 0,1ml /10 g body weight.

Spontaneous motor activity exploration. The psychomotor abilities induced by pregabalin were tested in the LE-8811 Actimeter device (Panlab) in order to investigate both global motor behavior and the number of escape attempts, during an eight-minute interval session. This device consists of three transparent cages each with eight infrared lights positioned in a frame around the cage and coupled to silent electronic counters. The apparatus is composed of a two-dimensional (X and Y axes) square frame, a frame support and a control unit.

Using this method spontaneous motor

activity was measured counting the number of times that an animal turns off a photocell beam. The system is completely modular: each frame may be used for evaluation of general activity: locomotors, stereotypic movements, rearing or exploration. Horizontal, vertical and stereotypic movements are registered simultaneously in the same experimental box.

Vertical movements were measured by number and length of bobbing. Horizontal movements indicate travel distance, and were measured based on time and count. In comparison, immobility was measured by the time that rats spent resting (11, 12).

Rats were placed individually in a cage and the spontaneous activity was measured by counting the number of light beam interruptions due to the animal's movement in the experimental area. The device is connected with a SeDaCom computer, which allows easy exportation of data in a format compatible with the Excel program for Windows.

Spatial working memory evaluation. The investigation of memory processes performance was assessed using the Y-maze model, based on the natural tendency of mice to explore novel environment (13, 14, 15).

This apparatus consists of 3 identical arms (40x9x16 cm, placed at 120 degrees from each other) and a central triangular zone. Each arm has walls with specific motifs all over the internal area allowing animals to differentiate it from the others. This experimental model was used to test if the rat could remember the arm it had just explored and would therefore enter one of the other arms of the maze (16, 17). Each animal was placed at the end of one arm and allowed to move unreservedly through the maze during an 8 min session. The short-term memory performance of mice was evaluated by counting the number of arm entries and determining the spontaneous alternation behaviour in the 8-minutes session. Alternation was defined as a consecutive entry in three different arms.

The alternation behaviour (%) was calculated using the following formula:

[number of alternations / (total number of arm visits – 2)] x 100 (18).

Data were analyzed using the ANOVA test implemented in SPSS 13.0 for Windows software. P-values less than 0.05 were considered statistically significant compared to those of the Control group.

The experimental protocols were approved by the University "Grigore T. Popa" Committee for Research and Ethical Issues. All procedures involving animals and their care were conducted in compliance with the international normatives and policies (19).

RESULTS

The results obtained in the Actimeter test were centralized, statistically interpreted and were represented in the following figures (fig. 1, 2).

The administration of pregabalin resulted in a dose-dependent reduction of mice horizontal movements (1313.45±1.21, respectively 1198.75±2.37), statistically significant ($p<0.05$) compared to the control group (1442.25±2.29) in the Actimeter test (fig. 1).

Intraperitoneal injection of pregabalin was associated with a dose-dependent diminution of vertical movements (372.25± 3.17, respectively 258.65±4.11), statistically significant ($p<0.05$) compared to the distilled water group (419.25±2.54), (fig. 2).

The treatment with two doses of pregabalin (PGB 10 and PGB 20) did not significantly modify the number of stereo-

typic movements (1511.25±2.32, respectively 1509.15±3.41) compared to the Control group (1514.25±1.53) in this behavioural experimental model in mice (fig. 3).

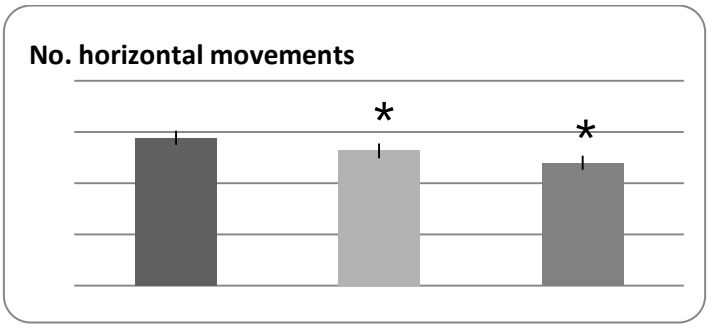

Fig. 1. Effects of pregabalin (10 mg/kbw and 20 mg/kbw) administration on horizontal movements in the Actimeter test (values expressed as mean ± SEM of horizontal movements for 6 animals; *p<0.05 vs Control).

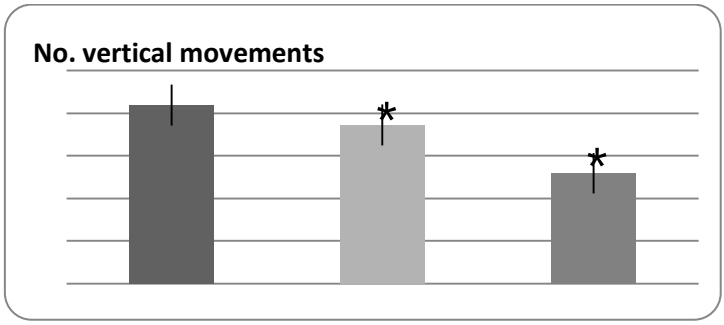

Fig. 2. Effects of pregabalin (10 mg/kbw and 20 mg/kbw) administration on vertical movements in the Actimeter test (values expressed as mean ± SEM of vertical movements for 6 animals; *p<0.05 vs Control).

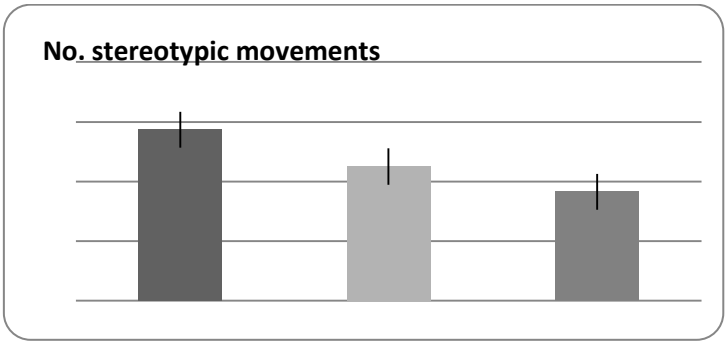

Fig. 3. Effects of pregabalin (10 mg/kbw and 20 mg/kbw) administration on stereotypic movements in Actimeter test (values expressed as mean ± SEM of vertical movements for 6 animals).

The results obtained in the Y-maze test were collected, statistically processed and were represented in the following figures (fig. 4, 5).

Intraperitoneal injection of the both doses (10 mg/kbw or 20 mg/kbw) of pregabalin did not significantly influence the number of arm entries compared to Control group in the same time interval, in the Y-maze assay (fig. 4). These results suggest that pregabalin administration did not modify the mice performances in this behavioural test (20).

The administration of PGB 10 did not induce modification of spontaneous alternation percent, compared to the Control group (fig. 5).

The use of PGB20 tended to increase the spontaneous alternation percent, but statistically non-significant compared to the group treated with distilled water in the Y-maze test (fig. 5). These results signify the lack of effect on the spatial memory performance of pregabalin administration in mice (13).

No significant changes were observed in the latency of the first arm visit, of the same arm return number and alternate arm return number between the groups treated with both doses of pregabalin and distilled water groups in this behavioural model in mice.

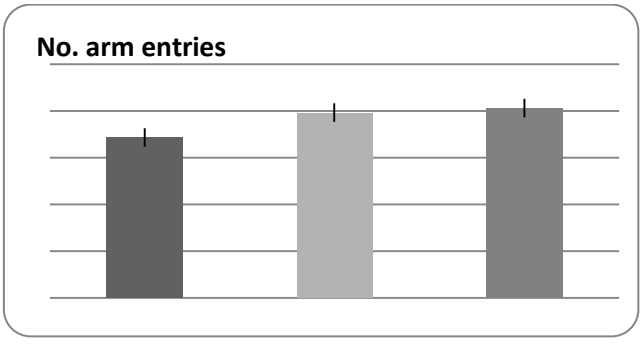

Fig. 4. Effects of pregabalin (10 mg/kbw and 20 mg/kbw) administration on arm entries number in Y-maze (values expressed as mean ± SEM of arm entries number for 6 animals).

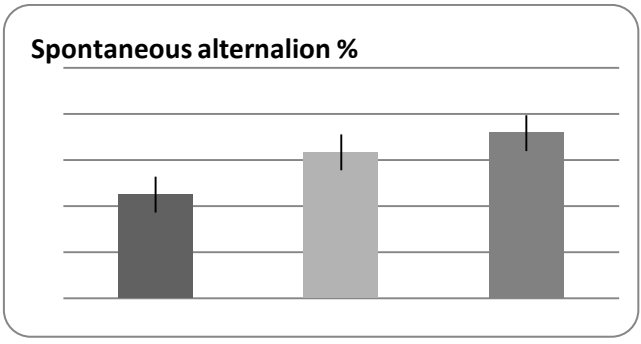

Fig. 5. Effects of of pregabalin (10 mg/kbw and 20 mg/kbw) administration on spontaneous alternation percent in Y-maze (values expressed as mean ± S.E.M of spontaneous alternation percent for 6 animals).

Moreover, the exploration capacity was not modified after the treatment with both doses of pregabalin in the same test in mice.

DISCUSSION

Limited literature data has been published regarding the involvement of pregabalin in spontaneous motor activity and cognitive processes of laboratory animals.

An experimental research conducted in the Elevated plus maze test revealed that pregabalin demonstrated evident short term anxiolytic effect, attenuating anxiety-like behaviours in mice exposed to traumatic stress. The authors of the study suggest that pregabalin may be an option for the treatment of anxious state after traumatic stress experience, lacking long-term protective or preventive actions (21).

Other experimental investigation proved that the administration of pregabalin attenuates ketamine-induced hyperlocomotor activity in an animal model of psychosis induced by ketamine, an NMDA receptor blocker that mimics the symptoms of schizophrenia (22).

Regarding the influence on cognitive functions it has been demonstrated that the treatment with pregabalin is associated with an impairment of the memory performance in step-down passive avoidance task in mice (23).

Using the behavioral experimental test, our research study has gathered information regarding three type of animal spontaneous motor activity: horizontal, vertical and stereotypic movements. The spontaneous motor activity is an elementary component of a normal animal behavior.

In our experimental condition the experiment proved that depending on the dose administered, pregabalin decreased mice horizontal movements, effect corresponding to a reduction of the general behavior exploration of the environment (24).

Intraperitoneal administration of pregabalin was associated with a diminution of vertical movements, parameter that reveals the animal trying to climb on the transparent walls of the registration cage, and is an indicative for attempt behavior, indirectly signifying fear and anxiety manifestations (11, 25).

In the Y-maze assay spontaneous alternation refers to the normal tendency of the animal to spontaneously choose alternate arms. Arm exploration was defined as entering at least the first third section of an arm (20).

In this behavioural model we noticed that neither 10 mg/kbw nor 20 mg/kbw pregabalin influenced the exploration capacity of animal placed in the device area.

Moreover, both doses of pregabalin did not modify the spontaneous alternation percent in the same behavioural experimental model in mice.

All these results suggest that pregabalin may be not involved in the mediation of cognitive function and learning capacity of laboratory animals.

CONCLUSIONS

The results reflect a significant dose-dependent diminution of the number of escape attempts, exploratory and self-maintenance spontaneous behaviour after pregabalin treatment, which could be correlated with an evident anxiolytic effect.

The study demonstrated that pregabalin did not modify the animal cognitive process performances or influence the short-term memory in the Y-maze test in mice.

NEWS

LYMPHANGIOMA OF THE PALATINE TONSIL

Lymphangioma of the palatine tonsil is a rare, benign lesion that presents as a tonsillar outgrowth and causes symptoms related to irritation and airway obstruction. Histologically, the mass has abundant dilated lymphatic channels in a fibrous stroma with lymphoid and adipose elements. A lymphangioma is mostly a congenital lesion consisting of a benign proliferation of lymphatic channels.Approximately 50% of these lesions are apparent at birth, with 80% to 90% detected within the first 2 decades of life. In contrast to congenital hemangiomas, lymphangiomas do not involute over time. Although these lesions tend to surround and sometimes invade nearby anatomic structures, they have no malignant potential. There is also considerable debate over the etiology of lymphangiomas, which may represent true neoplasms, malformations, or hamartomas. Three morphologic types of lymphangiomas are distinguished. Capillary, or simple, lymphangiomas are usually found in the superficial skin and composed of capillarysized, thin-walled lymphatic vessels. Cavernous lymphangiomas are subcutaneous lesions composed of mildly dilated, large spaces that are larger than those seen in capillary lymphangiomas. Cystic hygromas, the third type, are most common in the neck and composed of large, dilated, cystic lymphatic spaces. Thus, these 3 types of lymphangiomas can be differentiated from one another based purely on the characteristics of the component lymphatic spaces. In addition, combinations of the 3 types can sometimes be found in a single lesion. Therefore, the 3 types of lymphangiomas represent the same pathologic process along a spectrum and should be considered as a unified concept. Moreover, differentiating lymphangiomas on the basis of histologic type appears without clinical implications. Lymphangiomas tend to occur in places where lymphatics are abundant, with more than 90% of all lymphangiomas arising in the head and neck region. Most are found in the skin and subcutaneous tissues, but they have also been described in the larynx, parotid gland, mouth, and tongue. The palatine tonsil is a far less common site for the development of lymphangioma and has rarely been reported in the literature. Regardless of the uncertain pathogenesis of tonsillar lymphangiomas, these lesions have histologic features that differ from their counterparts in other anatomic locations. Although the lymphatic spaces of tonsillar lymphangiomas are frequently dilated, they are generally not as large or as prominent as in the lymphangiomas found elsewhere. Furthermore, the lymphoid and fibrous stromal components in tonsillar lymphangiomas are frequently more abundant than the lymphatic vessels. Thus, tonsillar lymphangiomas may represent a somewhat unique lesion. Reports in the literature use different nomenclature when referring to these lesions, such as tonsillar lymphangiomatous polyp, angioma, angiofibroma, fibrolipoma, polypoid tumor containing fibroadipose tissue, hamartomatous tonsillar polyp, and lymphangiectatic fibrous polyp. Because a lymphangioma may resemble a true neoplasm of the palatine tonsil clinically, the lesion must be removed for accurate histologic diagnosis and to rule out malignancy. Lymphangioma of the palatine tonsil is treated with surgical excision and has no recurrence once completely resected (Mardekian S and Karp JK. Lymphangioma of the Palatine Tonsil. Arch Pathol Lab Med. 2013;137:1837–1842).

TECHNOLOGICAL STEPS IN CLASS II EDENTATION PROSTHETIC REHABILITATION-CASE REPORT We presented a case of a Class II Kennedy edentation treated by a cast removable partial denture (RPD). Removable partial dentures with attachments present clear advantages to both patient and clinician. However, partial denture designs that try to improve morphological and functional benefits also should attempt to minimize the potential for harm. The practitioner should be aware of the principles of partial denture design that aim to maximize the functional stability of the denture and, at the same time, reduce the risk of partial dentures to cause long-term harm to the remaining teeth and supporting soft tissues. **Keywords:** CAST RPD, ATTACHMENTS, METAL CERAMIC BRIDGE.

This case presentation outlines the clinical and technological stages involved in realization of a cast removable partial dentures (RPD) that represents the likely treatment option for a class II Kennedy edentation. Patient's complaints were related to poor appearance and loss of masticatory function. The clinical examination established the status of the remaining natural teeth, of the existing restorations, of the potential denture-bearing areas, and of the soft tissue. In addition to establishing the dental status of remaining teeth, the examination should include an assessment of occlusal relationships and the availability of space for the prosthesis. Additional investigations were required, including radiographs of all abutment teeth, being important to get as much information as possible to establish the treatment plan. The principal objectives when treating partially dentate patients are to preserve the remaining teeth in a stable and healthy environment, to prevent further pathological change and to restore function (1, 2, 3).

The preliminary casts were poured into preliminary impressions, with care taken not to omit detailed recordings of remaining teeth and potential denture-bearing area. The preliminary cast was surveyed to establish the design of the partial denture, essential step in getting a good clinical result**.** We decided the abutment teeth (1.6, 1.3, 2.3, 2.6, 2.8), the outline of the major connector (a palatal strap) and the saddle areas.

The fixed component of the partial denture was represented by three metallic crowns on 1.6, 2.6 and 2.8, and a metal-ceramic bridge with attachments on 1.3-2.3.

The combined thickness of metal and

porcelain of the facial surface of a metal-ceramic crowns should be at least 1,4 mm to meet minimum strength and shade standards. A thickness of 0,4 mm of metal over the facial surface of the die is needed to prevent the alloy from flexing under stress. If the metal substructure flexes, applied porcelain will fracture. Bond strength between porcelain and metal is best when the metal surfaces are gently rounded. Corners or angles must be avoided on the porcelain-bearing surfaces. All junctions between porcelain and metal on the external surface of a restoration should be as close to a 90 angle as possible (4).

The wax patterns were made to a thickness of 0,4 mm in the areas that received porcelain. The wax was uniform and wrinkle-free to avoid holes. To control thickness with a little more precision we adapted a calibrated sheet wax over the die's surfaces. A cervical collar of l mm wide was carved into the oral half of the pattern. This collar helps ensure complete casting of the facial margin area and its bulk resists distortion when the porcelain cools from its firing temperature. In this stage, on the distal abutment teeth of the bridge the attachments were applied, in the denture's path of insertion. The wax patterns were prepared for investment by spruing and the mold was obtained after burnout stage. The dental alloy Brealloy C+B 270 (Bredent, Germany) was melted and cast with an automatic casting machine (ORCACAST M). After divesting the crowns framework were finished and prepared for veneering.

To eliminate the possibility of an incorrect shade, the opaque porcelain was used as a foundation and built thick enough to blot out the metallic frame. The opaque porcelain was mixed with distilled water to a creamy consistency, applied with a sable brush and vibrated to expel water that may be trapped. When the desired thickness has been reached, the opaque was condensed and smoothed. The opaque layer needs to be 0,2 mm thick to perform its masking function.

Fig. 1. Metallic framework of the fixed appliances

The body porcelain should be 0,75 mm thick or thicker to reproduce the chosen shade. The porcelain powder was mixed with distilled water to a thick, creamy consistency. First the body mix was applied, starting from the labial surface and progressing around to the lingual surface. The porcelain elements were build larger one sixth than the finished elements so that to allow for shrinkage of the porcelain. After the body porcelain was correctly shaped, the incisal area was rehabilitated. The bridge was brushed to smooth and condense the porcelain. The incisal porcelain was added to the contacts' areas of the proximal sides to compensate for the shrinkage of porcelain when it is fired. After the bridge was fired and cooled, necessary adjustments were done to realize the appropriate shape (fig. 2). The final fire of the bridge obtains a glaze for a desirable glossy surface (5, 6).

Fig. 2. The incisal porcelain with glossy surface

The fixed appliances were checked on the cast and after into the oral cavity, surveying the cervical adaptation, the rehabilitation of the morphology, the esthetic parameters, the anterior guidance path and the relationship with the antagonists.

Into the dental laboratory a light curing custom impression tray was made over the fixed bridge, to obtain the final impression and further the master cast (fig.3).

Fig. 3. Functional impressions

The master cast was surveyed to determine the path of insertion, undercut areas and the design of the framework of the removable partial denture. Interferences can profoundly influence the choice of a suitable path of insertion and may prevent the use of a partial denture.

The preparation for duplication included the blocking out and relieving steps. On the duplicated cast, after the surveying, the wax up for the metallic frame was done from preformed wax profiles, sprued and invested. The dental alloy used for casting the framework was Brealloy F 400 (Bredent, Germany).

After divesting, finishing and polishing, the metallic framework fitting was checked on the master cast and into the oral cavity.

To obtain the acrylic component of the saddles, after the jaws relationship record, the master casts were mounted into an articulator, using baseplates and occlusion rims. It is the dentist's responsibility to get proper jaw relationship records and accurate measurements in the patient's mouth. The technician must be sure that the arrangement of the denture teeth harmonizes with the natural remaining teeth (7).

During the clinical try-in several aspects were checked: the dimension of vertical occlusion (DVO), the aspect and functionality of the artificial arches. There are at least three objectives in setting of the denture teeth. The first is to achieve maximum chewing function and stability, the second is to avoid interfering with the pa-

tient's speech, and the third is to restore natural appearances (8, 9).

The wax up of the acrylic saddles were transformed into the final components through the flasking, resin curing, deflasking, finishing and polishing stages (fig. 4).

Fig. 4. The final aspect of the removable prosthesis

CONCLUSIONS

It is necessary for both the dentist and the patient to be convinced that the replacement of missing teeth will produce significantly more benefit than harm.

For many patients with teeth missing in the anterior part of the mouth appearance is an overriding consideration. As with appearance, the patient's concept of the problem is as important in deciding on a replacement as the problem itself.

In many cases tilting and over-eruption eventually lead to an instable occlusal relationship. If the missing teeth can be replaced before severe tooth movements occur, many TMJ disorders and malocclusions can be prevented

ETHICAL VIEWS, ATTITUDES AND REACTIONS OF ROMANIAN MEDICAL STUDENTS TO THE DISSECTING ROOM (Abstract) **Aim**: Our objective was to evaluate the attitudes and views of first year medical students towards cadaver dissection in anatomy learning and discuss various findings in relation with ethical problems). **Material and method**: The study was conducted at the"Iuliu Haţ ieganu" University of Medicine and Pharmacy, during the academic year 2012-2013 at the end of the second semester. There were 121 first year medical students included. We developed a questionnaire to asses among other, the degree of fear, anxiety and stress in the dissection room, methods of coping, ethical aspects of dissection and hand it to the students. **Results**: 34.7% of students experienced different levels of fear on exposure to the dissection room practical sessions. Many students experienced anxiety in reaction to dissection. In the first semester most students reported physical and behavioral reaction towards certain stimuli, with a decrease in the second semester. Recurring visual images of cadavers, reported by 57% of students in the first semester, dropped to 44.6% in the second semester. Students used most frequently the "rationalization and emotional detachment" as a coping method. **Conclusions**: Anatomists, most often the firsts who need to be aware of emotional and ethical issues, need to explain in detail the steps necessary for dissection and that dissection is performed with the respect of legislation, ethics and human rights. **Keywords:** ETHICAL ISSUES, DISSECTION, LEGISLATION, HUMAN RIGHTS, MEDICAL STUDENTS

Dissection of cadavers by the medical students is considered an essential requirement in learning anatomy and is the most universal and universally recognizable step in becoming a doctor (1).

Dissection of a human body during an anatomy course raises for first-year medical students questions about invasion of privacy, cadaver sources, dying and death. In anatomy, a student realizes that the first patient that he/she will care for is a dead one and experience considerable anxiety and stress (2).

Cadaver dissection has other learning outcomes besides anatomical learning, such as fostering teamwork and respect for the

human body, applying in practice the principles of bioethics and integration of knowledge from textbooks and didactic lectures with practice (3).

Anatomy can be defined etymologically using the term dissection (*Ana + tomein, Lat. cutting, incision, acting through dissection. Dissecare Lat., to cut apart*). The study of the human body without the use of dissection is a mere "lecture on the human form", which is the field of morphology, not anatomy (4).

The evolution of anatomy is, therefore, tightly bound to the history of dissection on human bodies. Ever since ancient times, corpses have been studied by scholars. In ancient Greece, Aristotle has practiced animal dissection, but in short time dissection was done on human corpses. Under the reign of king Ptolemeus, Herophilles (335 – 300 b.Chr.) was encouraged to practice vivisection on criminals. He was credited with no less than 600 such dissections (4). On the other hand, in ancient Rome human dissection was under religious and civic ban.

The precise descriptions from Galen's (129-216 A.D.) dissection textbook suggest that the author was no stranger to human corpse dissections, even though he admitted only to performing animal dissection.

The disappearance of the taboo on human corpse dissection occurred during the Renaissance period (XIVth–XVIth century) particularly due to medical scholars like Vesalius; the latter practiced systematic dissection for the first time (5). Hence, from the dissection method standpoint, the history of anatomy can be divided in prevesalist and postvesalist (4). The recognition of the utility of dissection and the subsequent shake-off of its licentious attribute has allowed the spectacular outspread of this scientific practice.

A parallel statistic on the number of hospital abandoned and donated corpses, respectively, at the Paris Faculty of Medicine between 1900 and 1999 has shown the progressive decrease of hospital abandons from nearly 2000 in the year 1900 to under 50 in 1980. The latter level has not changed ever since.

A study on records of the source of corpses used in the Cluj-Napoca anatomy department between 1987 and 2012 has found no donations to have taken place, the bodies for dissection being supplied by hospitals morgue services and forensic departments from Cluj-Napoca and nearby districts.

Ethical dilemmas concerning dissection. In the last decades, medicine is subject to probably the most extensive development from its long history. Terms such as biotechnologies or genetic engineering were not long ago, the privilege of science-fiction; nowadays, they stand as important fields of research, expanding the scientific knowledge. With all the progress of medicine, many domains maintain or rise new subjects of disputes, controversies or dilemmas. The role of the human tissue, broad sense, for the progress of medical sciences, either research or clinical practice, is not to be argued. Nonetheless new legal and ethical issues arise, reflected by the growing interest of public opinion in these matters (6, 7).

There is a special concern regarding the protection of individuals from whom the tissues come/are harvested and their proper use. The human body, even if dead, is referred to as tissue, broad sense. There is a special preoccupation for the respect to the person and the human body. Usually,

corpses and large body parts, that are easy to be recognized, are paid more respect than fragments of tissue, such as vials of urine or blood (8); it seems that the latter are perceived differently.

Respect for the human body, including corpses, was paid through all mankind history, starting from legal regulations and continuing with moral, social, ethical and religious regulations, which protect individuals, life, integrity and propriety, and regulates burial and incineration, and the respect paid to the dead (9).

Even so, these conditions are neither absurd nor arbitrary, corpses being used in the interest of the society, with the proper respect. For medical sciences, this contributes to the development of medical research, new means of diagnosis and therapy, or for medical education.

Cadaver dissection is performed by medical students during practical lessons/classes for the study of anatomy, by surgeons for studying new approach in surgical interventions. Dissection is performed for didactical or research purposes, obeying the law and the principles of medical ethics (10, 11, 12, 13).

Beneficence involves two fields - the individual and the society. Dissection involves applying the beneficence on the social level, through the public institutions and their benefits to society. Dissection performed during anatomy classes has didactic and scientific characteristics, contributing to professional formation and development of medical students, who in turn will become physicians, or of surgeons, pathologists or forensic specialists.

The principles of bioethics are stated in The Decalogue of Masci, The International Code of Medical Ethics and in The Deontological Code of The Romanian College of Physicians (14).

The Decalogue of Masci states the absolute respect of the patient, regardless of age. By extent, we can affirm the necessity of respect for the deceased human body, and in our case, for the corpse for dissection (15).

Perhaps the most important rule is the moral obligation of continuous professional self-improvement. Let there be the case of specialists dissecting corpses for professional development, such as achieving new techniques, surgical procedures or the study of anatomic position.

The International Code of Medical Ethics imposes to maintain high professional standards. These rules stress those mentioned by the Decalogue of Masci, mostly those concerning continuous self-improvement. In order to respect this rule, standard procedures in harvesting and fixing corpses and performing dissection are applied. Another rule is keeping the absolute secret concerning the patient, even after his/her death (16).

The Deontological Code of The Romanian College of Physicians states the principle of autonomy by saying that the physician is in the service of the human person, and the secret lays even after the treatment is over or the patient is dead (17).

Many medical schools from the US (18), the UK (19), Australia (20), and the Netherlands (21) have already quit dissection by various reasons (22). Out of many reasons, one has a certain importance for our case. The study conducted by Charlton and Smith (2000) reveals that the experience during an anatomy class can induce stress among some of the medical students (23). A small percentage of them may have feelings of horror, apprehension, guilt, wonder, gratitude, sadness and even over-

whelming physical reactions. Finkelstein and Mathers (1990) conducted a survey at Standford University Medical School and found out that five percent of the questioned students reported marked disturbance including nightmares, intrusive visual images, insomnia, depression, and learning impairments (24) According to Gustavson (1988), first year medical students have concerns about becoming "desensitized" to the human body, due to the emotional responses to the dissection process (25). Dinsmore et al (2001) found similar results (26). Penny (1985) found out that the strongest reactions were in anticipation of dissection (27).

Negative emotional experience among dissection also crosses cultural barriers. Nnodim (1990) found that about a quarter of the Nigerian students reported an increase in frequency of mental and physical symptoms suggestive of depression, and 5% remained highly upset at the halfway point of the course (28) A later study of the same author (1996) found no cultural differences between the student's attitudes (29).

If the principle of nonmaleficience is applied to patients, wouldn't it be right to apply the same principle to healthy individuals not suffering from a disease or an infirmity, as is the case of the medical students? Can the physical and psychological impairments inflicted by dissection be considered as violation of the principle of nonmaleficience?

Furthermore, we have to discuss about the right to intimacy and private life of the patient, which, during a dissection is exposed to looks and comments from the students.

A minimal distinction between dissection and desecration must be made. Dissection is performed in the spirit of respect towards the human body for precise scientific purposes, obeying the law and regulations, and by standard procedures. For example, the head and the face are kept covered until the study of that specific anatomic segment; the body parts that are not subject to current anatomy classes are kept covered. Dissection starts with skin dissection and continues with the other parts/organs.

We can state that dissection forges the spirit of the future physician, contributing to the understanding of scientific notions, but also to the forming and polishing of the character, by understanding the moral values, the gift of life, implications of the disease and lifestyle, respect towards death and cultivating empathy for the future patients (25).

This study was carried out to evaluate the attitudes and views of first year medical students towards cadaver dissection in anatomy learning and discuss various findings in relation with ethical problems of using human body for teaching and scientific research and with reports available in the scientific literature.

MATERIAL AND METHODS

The present study was conducted at the University of Medicine and Pharmacy "Iuliu Haţ ieganu", during academic year 2012-2013, at the end of the second semester. The subjects included in the study were 121 first year medical students in General Medicine who were willing to participate in the study. We explained the objective of the study and a questionnaire was given to the students. A psychologist, a psychiatrist and an anatomy instructor developed the questionnaire from interviews with medical students. Test-retest reliability of the ques-

tionnaire was conducted on 20 students with an interval of a week. The test preserved anonymity of the students and contained multiple choice questions about: degree of fear of the dissection room (DR), anxiety and stress in reaction to DR, sources and degree of disturbance in the DR, methods of coping, previous experience of a dead body before dissection, mental preparation for dissection, sympathy and respect for cadaver, ethical aspects of dissection, importance and indispensability of dissection for studying medicine.

RESULTS

121 students answered to the questionnaire 35 (28.9%) were males and 86 (71.1%) females. The mean age of the students was 19.79 (±0.717). Regarding religion, 75 (62%) were Orthodox, 21 (17.4%) Catholic, 12 (9.9%) Methodist, 11 (9.1%) Neo-protestant Cults and 2 (1.7%) without religion. 65 students (53.7%) were practicing their religions. For 22 (18.2%) of the students the religion is very important, for 53 (43.8) is moderately important, for 38 (31.4%) is slightly important and for 8 (6.6%) is not at all important.

A total of 65.3% of students reported no fear before they entered in the DR, and 34.7% reported varying degree of fear, out of which 9.9 were very scared.

First table shows the behavioral and physical reaction of students to the DR. Nausea; trembling and recurring visual images of cadavers were the most common reaction experienced by the students in the first semester.

TABLE I
Stress and anxiety in reaction to dissection room

Reaction	Percentage of students (Number of students) / First semester / Second semester									
	Never		Occasional		Often		Frequently		Always	
Fainting	71.9 (87)	81.0 (98)	20.7 (25)	19 (23)	2.5 (3)	0 (0)	5 (6)	0 (0)	0 (0)	0 (0)
Dizziness	65.3 (79)	76 (92)	20.7 (25)	6.6 (8)	4.1 (5)	6.6 (8)	13 (10.7)	13 (10.7)	5(6)	0 (0)
Palpitation	82.6 (100)	90.9 (110)	3.3 (4)	2.5 (3)	11.5 (14)	4.1 (5)	0(0)	2.5 (3)	2.5 (3)	0 (0)
Left de DR	72.7 (88)	79.3 (96)	6.6 (8)	5 (6)	7.4 (9)	2.5 (3)	10.7 (13)	10.7 (13)	2.5 (3)	2.5 (3)
Trembling	66.1 (80)	78.5 (95)	31.4 (38)	17.4 (21)	2.5 (3)	4.1 (5)	0 (0)	0 (0)	0 (0)	0 (0)
Nausea	46.3 (56)	68.6 (83)	47.1 (57)	28.9 (35)	6.6 (8)	2.5 (3)	0 (0)	0 (0)	0 (0)	0 (0)
Sweating	76.9 (93)	79.3 (96)	10.7 (13)	8.3 (10)	1.7 (2)	1.7 (2)	10.7 (13)	10.7 (13)	0 (0)	0 (0)
Loss of appetite	73.6 (89)	86.9 (105)	7.4 (9)	1.7 (2)	12.4 (15)	5 (6)	6.6 (8)	6.6 (8)	0 (0)	0
Insomnia	79.3 (96)	90.9 (110)	18.2 (22)	6.6 (8)	2.5 (3)	2.5 (3)	0 (0)	0 (0)	0 (0)	0 (0)
Recurring images of cadavers	43 (52)	55.4 (67)	50.4 (61)	40.5 (49)	6.6 (8)	4.1 (5)	0 (0)	0 (0)	0 (0)	0 (0)

TABLE II

Degree of disturbance related to certain stimuli in the dissection room

Stimuli in the DR	Percentage of students (Number of students) First semester / Second semester									
	None		Slight		Moderate		High		Very High	
Smell of DR	9.1 (11)	9.9 (12)	23.1 (28)	35.5 (43)	40.5 (49)	27.3 (33)	6.6 (8)	8.3 (10)	20.7 (25)	19 (23)
Sight of cadavers	28.1 (34)	38.8 (47)	40.5 (49)	33.9 (41)	30.6 (37)	26.4 (32)	0.8 (1)	0.8 (1)	0 (0)	0 (0)
Looking at the cadaver's face	32.2 (39)	38 (46)	19 (23)	17.4 (21)	38 (46)	40.5 (49)	5.8 (7)	4.1 (5)	5 (6)	0 (0)
Touching certain parts of cadavers	57.9 (70)	64.5 (78)	32.2 (39)	29.8 (36)	7.4 (9)	5.8 (7)	0 (0)	0 (0)	2.5 (3)	0 (0)
Fears of infection	62 (75)	65.5 (79)	19.8 (24)	17.4 (21)	6.6 (8)	6.6 (8)	11.6 (14)	10.7 (13)	0 (0)	0 (0)

In the second semester we noticed a decreased of physical reaction to the DR.

In the second table are gathered the reactions to the stimuli in the DR.

The most disturbing was the smell, only 9.1 % of the students don't have a problem with the smell and looking at the cadaver's face (67.8% of the students have some degree of apprehension).

In Table III are presented the coping methods with the DR. Most of the students (74.4%) used rationalization and emotional detachment as coping mechanism.

A percentage of 35.5% have already seen a dead body before entering the DR.

In our study all the students considered that cadaver dissection is ethically acceptable. An overwhelming majority of students (78.5%) considered cadaver dissection as important and indispensable in anatomy learning.

Only 46.3% of the students think that the cadaver they dissected was once a human being.

TABLE III

Methods of coping

Coping mechanism	Percentage of students				
	Never	Occasional	Often	Frequently	Always
Talking with another students	54.5(66)	21.5(26)	24(29)	0(0)	0(0)
Talking with anatomy instructors	90.1(109)	9.9(12)	0(0)	0(0)	0(0)
Rationalization, emotional detachment	25.6(31)	8.3(10)	20.7(25)	29.8(36)	15.7(19)
Humor	32.2(39)	23.1(28)	15.7(19)	18.2(22)	0(0)
Praying	72.7(88)	9.9(12)	15.7(19)	1.7(2)	0(0)

DISCUSSION

First year medical students experienced unpleasant or frightening feeling on their first exposure to dissection and dead bodies (30) as part of the curriculum.

To deal with difficulties that the stu-

dents might encounter, their reactions and feelings should be known (25).

This study indicates that 34.7% of students experienced different levels of fear on exposure to the DR practical sessions.

Other study has found percentage between 5% (31) and 50% (32).

In the first semester most of the students reported variable degrees of physical and behavioral reaction towards certain stimuli in the DR, the reaction decreased in the second semester. It seems that there is a consensus that all medical students may experience a variable degree of fear on exposure to DR (31, 32, 33)

Recurring visual images of the cadavers were reported by 57% of students in the first semester and by 44.6% of students in the second semester. This figure was much higher than (9.7%) reported in UK (34).

In this study, smell was the most disturbing stimulus, where 90% of students showed a variable degree of disturbance due to the smell, follow by looking at the cadaver face (67.8%).

Many students go through a process of psychological accommodation (35) due to rapid acquisition of coping mechanism to death (36).

The present study showed that the students have used different coping methods to overcome their fear in the DR. The most frequently used method by students was "rationalization and emotional detachment" (74.4%), followed by humor (67.8%).

CONCLUSIONS

Our study shows that many students experienced anxiety in reaction to dissection.

Anatomists are often the first teachers in the curriculum who need to be aware of emotional and ethical problems (2, 35). More attention should be paid to the first encounter with corpses, and students should be offered the opportunity to discuss their emotions.

Students should be make aware of the possibility that they will develop symptoms in reaction to dissection, that the symptoms are normal and they could talk about this with the anatomy teachers or in psychological counseling.

There is a need to explain in detail to students the steps necessary for the dissection and the fact that dissection is performed with the respect of legislation, ethics and human rights.

HEPATORENAL DYSFUNCTION IN SEPSIS, EPIDEMIOLOGICAL, CLINICAL AND LABORATORY ASPECTS (**Abstract**): The major impact of sepsis-induced multiple organ dysfunction on healthcare system in the European Union was estimated at 90.4 cases per 100000 inhabitants, compared to 58 per 100000 for breast cancer. The association of organ dysfunctions in terms of both the number of dysfunctions and the degree of organ dysfunction is the most powerful predictor of death in sepsis. **Aim:** To find medical and statistical correlations in hepatorenal dysfunction in sepsis patients. **Material and Methods:** This retrospective study included 117 patients diagnosed with sepsis at the Iasi Infectious Diseases Hospital, patients who presented liver/renal and other organ dysfunctions. The clinical, etiological, and laboratory data, and APACHE II prognostic scores were analyzed. The data were processed using *SPSS version 16.0*. **Results:** The etiological agents were Gram positive as well as Gram negative bacteria, and 40% of sepsis patients with hepatic/ kidney dysfunction presented hepatorenal syndrome. **Conclusions:** Over one-third of patients with sepsis-related hepatorenal dysfunction had a creatinine clearance of less than 30 ml/min, and we found statistical correlations between serum creatinine and APACHE II score. There were no statistically significant differences between the survival curves of patients with hepatorenal syndrome and those with sepsis-related hepatorenal dysfunction. **Keywords:** SEPSIS, HEPATORENAL DYSFUNCTION, KAPLAN MEIER CURVE

The major impact of sepsis-induced multiple organ dysfunction on healthcare system in the European Union was estimated at 90.4 cases per 100000 inhabitants, compared to 58 per 100000 for breast cancer (1). It is estimated that there are 1.8 million cases annually, but this figure reflects low recognition or diagnosis. Recent estimates show an incidence of sepsis in intensive care units of 0.25 to 0.38 per 1000 inhabitants, suggesting two million admissions to intensive care units (2, 3). Data are from intensive care units and research centers in UK Intensive Care National Audit and Research Centre (ICNARC) covering the last months of 2005 reported 8300 deaths from severe sepsis. Mortality rate from severe sepsis was estimated in many studies, ranging from 28% to 50% (4, 5, 6).

In the United States the incidence of severe sepsis is estimated to 300 cases per 100,000 inhabitants of which about half outside emergency units (7, 8). One in four patients who developed severe sepsis dies during hospitalization. Septic shock is as-

sociated with the highest mortality rate, approaching 50%. The association of organ dysfunctions in terms of both the number of dysfunctions and degree of dysfunction is the most powerful predictor of death in sepsis. Epidemiological controversy arises when discussing about treated cases, since eligibility for treatment differs according to time and country, with different cultural perspectives on end-of-life, differences in access to emergency departments; level of health insurance other economic and cultural factors (7, 9).

Sepsis encompasses a tremendously heterogeneous group of patients with a great variability of underlying conditions, infection sites, with a multitude of microbial agents with high virulence and variations in concentration, and with differences in inflammatory response and immunological context. Sepsis can be caused by a small inoculum of etiologic agent in conditions of high pathogenicity or reduced host defense capacity. The inflammatory response may be excessive when the microbial toxin or microorganism is very aggressive, or when genetic predisposition leads to important changes at the level of cellular effectors involved in the inflammatory response (10).

MATERIAL AND METHODS

The study was conducted in the Iasi Hospital of Infectious Diseases and included patients diagnosed with sepsis in the interval November 2012 - April 2014. Data in their medical records and annexed documents were analyzed. All patients signed upon admission an informed consent for the use of their data for research purposes. This study was performed in compliance with the Declaration of Helsinki, and was approved by the Ethics Committee of the University of Medicine and Pharmacy of Iasi.

A number of 117 sepsis patients presenting hepatorenal dysfunction, hepatorenal syndrome (HRS), and other organ dysfunctions were included in the study. The demographic data (age, gender, origin), length of hospital stay, laboratory data, etiology, baseline and post-baseline laboratory data, APACHE II prognostic scores, past history of liver/kidney dysfunctions, disease improvement or progression to death were analyzed. The diagnosis of sepsis was made according to the definition of suspected or documented infection and presence of inflammatory systemic response syndrome (at least two of the following criteria: fever/hypothermia, tachycardia, tachypnea, and leucocytosis/ leukopenia).

The diagnosis of severe sepsis referred to patients with the acute organ dysfunction: cardiac, renal, hepatic, respiratory and circulatory failure disseminated intravascular coagulation or shock. Biological samples were analyzed in the laboratory of bacteriology by direct examination, cultures, fixation method, and latex agglutination. We created an EXCEL database including the descriptive data and the qualitative and quantitative parameters, and used SPSS version 16.0 for data processing. The following tests were used: *t student test*, *chi-square test*, *Pearson correlation* for normally distributed variables, and *Spearman rank-order correlation* independent of data distribution types. When data were not normally distributed we used the *Mann-Whitney test* for comparing two sets of variables, the *Pairwise Comparison test* when sample sizes were small; *Kruskal-Wallis test* was used to compare multiple sets of data.

RESULTS

In age groups 50-70 and over 80 years there was a female prevalence; rural/urban distribution of the study patients was approximately equal.

The identified etiologic agents varied widely: methicillin-sensitive *Staphylococcus aureus (*MSSA), methicillin-resistant *Staphylococcus aureus* (MRSA), *Staphylococcus epidermidis*, *Streptococcus spp.*, *Enterococcus spp*. as well as beta-lactamase producing and not-producing Gram negative bacilli: nonfermenting Gram negative bacilli, *Escherichia coli*, *Klebsiella pneumoniae*, *Proteus mirabilis*, *Pseudomonas aeruginosa*.

Patients with hepatorenal dysfunction were predominantly referred from cardiology, diabetes, neurology and gastroenterology departments (fig. 1). At baseline the inflammatory syndrome was well represented, with an average of 13200 white blood cells/mm³ in the case of hepatorenal syndrome, average CRP level equal in patients with or without hepatorenal dysfunction, average fibrinogen level of 6.2 g/L in patients with hepatorenal syndrome compared to 5.8 g/L in those with hepatorenal dysfunction.

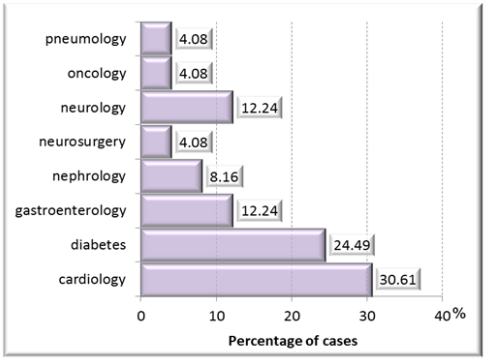

Fig. 1 Departments referring patients with sepsis and hepatorenal dysfunction

Only 40% of patients with hepatorenal dysfunction presented a hepatorenal syndrome (fig. 2), the average creatinine clearance rate in these patients as calculated by the Cockroft-Gault formula being 33 mil/min.

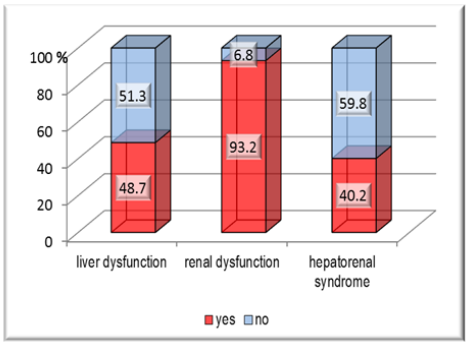

Fig. 2 Distribution of patients according to the presence of liver dysfunction, renal dysfunction and hepatorenal syndrome

Over 37% of the patients had a creatinine clearance below 30% (fig. 3). Using the Kruskal Wallis test (equivalent to ANOVA), we found a statistically significant relationship between creatinine clearance values and the severity of sepsis calculated by the APACHE score (*calculated* $p = 0.44$).

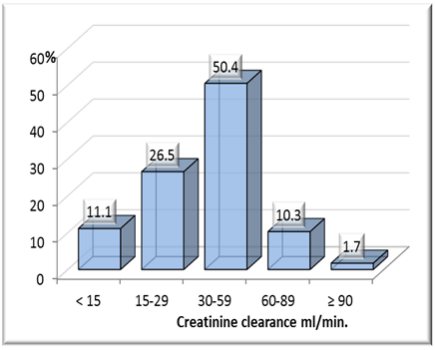

Fig. 3 Creatinine clearance in patients with sepsis-related hepatorenal dysfunction

The outcome of patients with hepatorenal dysfunction was favorable in most cases (69%), sometimes requiring referral to other departments (10.2%) and less than one-third (29%) died (fig. 4).

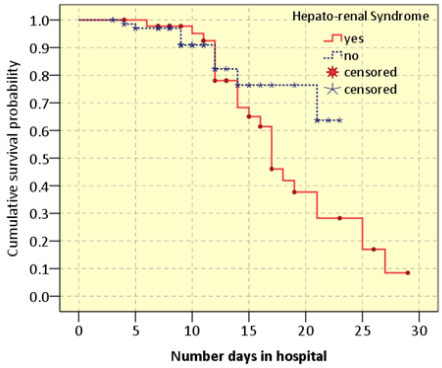

Fig. 4 Kaplan Meier survival curve in patients with hepatorenal syndrome and hepatorenal dysfunction in sepsis

DISCUSSION

Until 2006 definitions for HRS showed that it is a reversible functional kidney damage that occurs in patients with advanced liver cirrhosis or fulminant liver failure and is characterized by reduction in glomerular filtration rate and renal plasma flow in the absence of other causes of renal dysfunction (11). With the rise of knowledge, it was shown that the original definition lacked concision with respect to a large number of exclusion criteria, sepsis being one of them (12). Before revision, guidelines proposed, in 2007, the exclusion of bacterial infections for the HRS diagnosis (13).

The major mechanism of HRS consists of an extreme renal vasoconstriction caused by activation of Na retention and vasoconstrictor systems, resulting in a very low glomerular filtration rate (14). HRS type I occurs as a consequence of a severe reduction in the circulating volume caused on one hand by a major splanchnic vasodilatation and, on the other, by decreased cardiac output, this type of disorder being present in sepsis.

In our study, twenty-two percent of the patients with hepatorenal dysfunction received antibiotic therapy prior to admission, some of them having a change in their antibiotic regimen during hospital stay: most patients (73.9%) received a single antibiotic regimen, one third required only one change in their antibiotic regimen, while one patient received three antibiotic therapy schemes.

According to statistical analysis data, no statistically significant difference in the two functions defining the survival curve between the patients with hepatorenal dysfunction and hepatorenal syndrome was found.

CONCLUSIONS

Over one-third of the patients with sepsis-related hepatorenal dysfunction had a creatinine clearance below 30 ml/min, and we identified statistical correlations between serum creatinine and calculated APACHE II score.

No statistically significant differences were found between the survival curves Kaplan Meier of patients with hepatorenal syndrome and of those with sepsis-related hepatorenal dysfunction.

DISCOVERY OF CLOSTRUBIN, AN ANTIMICROBIAL AGENT ISOLATED FROM ANAEROBIC BACTERIA

Genome analysis of *Clostridium beijerinckii* revealed several cryptic gene clusters for secondary metabolite biosynthesis. When cultured under various conditions, *C. beijerinckii* produced a novel metabolite - a deep purple pigment, named clostrubin which was further isolated and its structure elucidated. The pentacyclic polyphenol folds in a manner that forms a perifused ring system (benzo[a]tetraphene), unusual for natural products. This is the first reported aromatic polyketide from an anaerobic bacterium. The study demonstrated that clostrubin is a potent antibiotic with activity against various pathogenic bacteria, such as MRSA, VRE, and mycobacteria (MICs of 0.12-0.97 μM) (Pidot S, Ishida K, Cyrulies M, Hertweck C. Discovery of Clostrubin, an Exceptional Polyphenolic Polyketide Antibiotic from a Strictly Anaerobic Bacterium. *Angew Chem Int Ed Engl*. 2014. doi: 10.1002/anie.201402632. [Epub ahead of print]).

4. Family Medicine Practice, Permanent Medical Center "Plugari", Iaşi

CLINICAL AND EPIDEMIOLOGICAL ASSESSMENT OF THE INCIDENCE OF ARTERIAL HYPERTENSION IN A PERMANENT MEDICAL CENTER (Abstract): The present study shows the results of monitoring, evaluation and prediction of health status in a patient group with hypertension (HTN) seeking care in a permanent medical center. *Materials and methods*: The study evaluated 144 patients registered at the Permanent Medical Center of the Plugari village, Iaşi County, who were diagnosed with HTN between 2011 and 2013. The study group included 80 male patients with an average age of 51.25 years with a diagnosis of essential hypertension (EHTN) stage I, II or III and 64 female patients (group II), with an average age of 48.4 years. **Results**: 44 patients (30.55 % of the total number of patients) were diagnosed with HTN stage I, of whom 27 were female (61.36 %) and 17 were male (38.64 %); 69 patients (47.93 %) had HTN stage II, of whom 21 were female (30.43 %) and 48 were male (69.57 %), and 31 patients (21.52 %) had HTN stage III, of whom 16 were female (51.61 %) and 15 were male (48.39 %). **Conclusions**: Patients at high risk for HTN and those with mild and moderate clinical forms were surveyed and were early treated. Economic and social benefits were achieved due to lower hospitalization costs, fewer days of temporary disability and reduced medical retirements. In our study groups, HTA had a higher prevalence, especially in men. **Keywords**: HYPERTENSION, CLINICAL EPIDEMIOLOGY, RISK FACTORS.

Clinical epidemiology of cardiovascular diseases (CVDs) has become increasingly important due to the fact that cardiovascular mortality ranks first nowadays in the world, especially in economically advanced countries, while there is also a trend of explosive growth in developing countries such as Romania (1, 2, 3).

Clinical research of CVDs puts the individual at the center of its development. Clinical epidemiology encompasses issues arising from the features of the larger population, from which these patients are drawn, aimed at identifying and managing risk factors that lead to disease and at finding effective means to prevent and control diseases.

The risk factors (RF) represent one of the major underlying elements of CVD

epidemiology, as they provide a rational and scientific basis for prevention and cure. Establishing the number of RF and their impact on CVD morbidity is a requirement of modern medicine, in which preventive measures gradually become just as important as treatment plans. The perfect case would be to succeed in replacing therapy with prevention (3,4,5).

The major aim of this study is to evaluate the clinical and epidemiological factors that play a role in the onset and progression of the disease, with a special interest in diagnostic stages and disease management in patients seeking care in a permanent medical center (6).

MATERIAL AND METHODS

The study included 144 HTN patients registered at the Permanent Medical Center of the Plugari village, Iaşi county between 2011 and 2013. They were divided into two groups: the first group included 80 male patients with an average age of 51.25 years with a diagnosis of essential hypertension (EHTN) stage I, II or III and 64 female patients (group II), with an average age of 48.4 years.

TABLE I

Age-related variability of blood pressure

Age groups (years)	Men		Women	
	SBP	DBP	SBP	DBP
20-29	126.1	75.8	114.5	77.0
30-39	125.5	80.8	117.2	70.8
40-49	133.8	84.2	124.6	82.3
50≥65	149.7	91.0	142.0	85.3
Group average	137.1	84.8	126.6	81.7

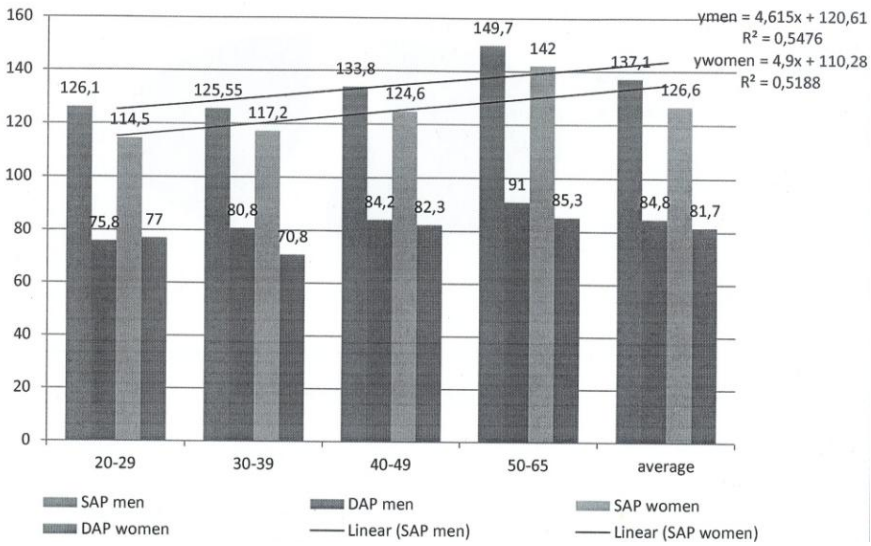

Fig. 1. Arterial pressure variability in relation with age group

Plugari village is divided into three rural areas with a plain landform, which are crossed by two rivers of local importance. Its population, mainly Orthodox, is undergoing a continuous demographic decrease, due both to migration to urban areas and especially to low birth rate and high mortality caused mainly by the aging trend in the community. Residents are employed in livestock farming and field cultivation (grain, fodder and vegetables).

The clinical and epidemiological investigation included history, objective clinical examination and recording blood pressure. Mathematical statistical evaluations were made using the *EpiInfo* 2000 program and X^2, DS, p, t-Student tests.

Mean values of systolic blood pressure (SBP) and diastolic blood pressure (DBP) age groups based on decades showed a general tendency of progressive increase (tab. I, fig. 1).

The clinical and epidemiological sheet provided information on eating habits (lipid intake, daily consumption of cigarettes, smoking duration in years), lack of physical activity, physical effort, stress, behavioral types, dominant moods (aggressive, depressed, anxious, etc.)

RESULTS AND DISCUSSION

In population studies, the difference between "normal" and "pathological" is hard to demonstrate, due to variations depending on geographic area, lifestyle and socioeconomic characteristics. This is why our study centers upon the elderly (5).

As people grow old, they accumulate previously acquired und untreated diseases, so that at different ages an "inventory" of co morbidities at various stages can be found. Such associations express rather "the disease-related age" than "age-related diseases".

In the study group, the following conditions were diagnosed: hypertension (144: 3.84%), liver cirrhosis (152:4.06%); ulcer disease (129:3.44%); malignant diseases (109:2.91%); ischemic heart disease (102: 2.72%); chronic renal failure (14:0.37%); congenital anomalies of circulatory system (9:0.24%), chronic pulmonary heart disease and tuberculosis (5: 0.13%) (fig. 2).

There was a high ratio of CVDs, which are the leading cause of mortality, in all examinations of adults aged over 65 years made in the family doctor's practice. It is widely recognized that cardiovascular diseases have a chronic, disabling course and a poor prognosis, but early detection with screening tests is possible and required, especially in persons at high risk, leading to major medical and socioeconomic benefits.

HTN has an important place in the group of CVDs, as it affects about 10% of the general population, 25% of persons aged over 40 and 40% of those aged over 64. Although it is estimated that approximately 50% of HTN patients have mild forms of disease, the Framingham study has shown that even small increases in blood pressure are potentially dangerous, leading to shorter life expectancy (9, 10, 11).

In our study, group I included 80 male patients with an average age of 51.25 years with a diagnosis of essential hypertension stage I, II or III and group II included 64 female patients with an average age of 48.4 years (tab. II, fig. 3).

The most important mechanisms involved in the etiology and progression of HTN are as follows: increased sympathetic activity, altered transmembrane transport of ions (especially sodium and calcium ions), increased vascular reactivity due to the important role of endothelium in the regu-

lation of the vasomotor tone, stimulation of the renin-angiotensin-aldosterone system, dysfunction of local self-regulation mechanisms (prostaglandins and kinin-kallikrein system) metabolic factors, structural changes of blood vessels (8, 9, 10).

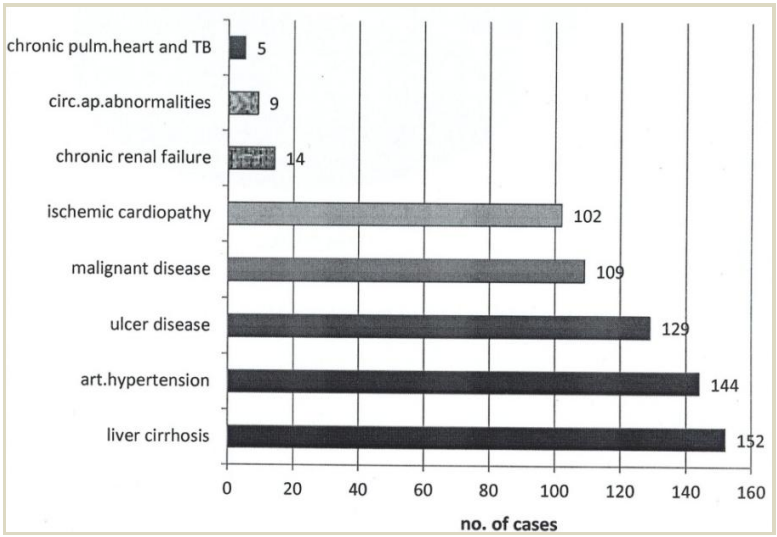

Fig. 2. Co morbidities registered in studied patients

TABLE II

Limits and the average age of the patients included in the study

Group	Gender	Number of patients	Age limits	Average age
I	M	80	42-64	51.25
II	F	64	40-65	48.4

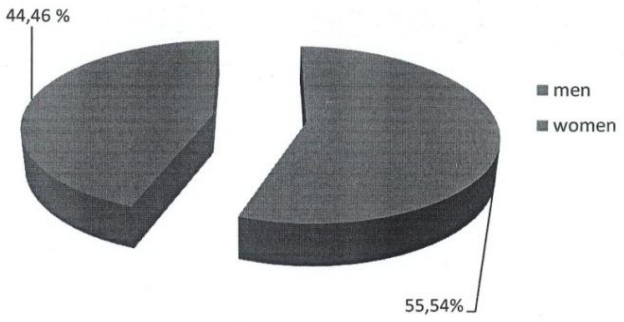

Fig. 3. Distribution of cases by sexes

Epidemiological surveys suggest that CVDs epidemic in Eastern Europe might be caused also by other risk factors, such as psychosocial stress, environmental pollu-

tion and nutritional deficiencies that might increase oxidative stress. This would be the result of an imbalance between different risk factors, as not only free radicals, but also protective antioxidants are produced, leading to an acceleration of atherogenesis. Recently, various infectious factors were also proposed as risk factors (10, 11).

Our study has rated the HTN risk factors, as follows: behavioral type (41.2%), a diet rich in fat and eggs (38.2%), stress (37.9%); sedentary lifestyle (25.8%), daily alcohol consumption (16.47%) excess salt intake (9.0%), passive smoking (4.7%) as compared to active smoking (1.94%). In women, endocrine disruption, especially during preclimacteric years, was also considered.

The analysis of the distribution of HTN staging showed that 44 patients (30.55%) were diagnosed with HTN stage I, of whom 27 were female (61.36 %) and 17 were male (38.64 %) ($p = \leq 0.05$); 69 patients (47.93%) had HTN stage II, of whom 21 were female (30.43 %) and 48 were male (69.57 %) ($p = <0.005$) and and 31 patients (21.52 %) had HTN stage III, of whom 16 were female (51.61 %) and 15 were male (48.39 %) ($p \geq 0.05$) (fig. 4).

The process of atherosclerosis caused stroke in some patients with HTN stage II (24 cases: 16.66%).

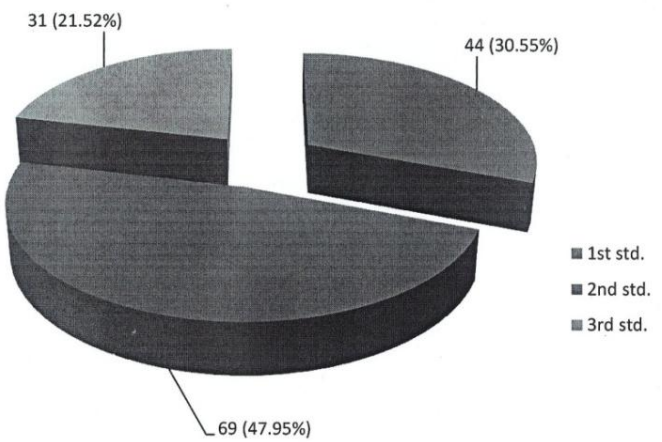

Fig. 4. Stadialisation of studied patients

Patients included in the study were on antihypertensive drug therapy (1, 2, 3 or more antihypertensive drugs) when blood pressure was measured, having a significant influence on results.

For instance, 42 patients (29.16%) have already received an antihypertensive drug; 59 patients (40.97%) two drugs and 43 patients (29.87%) over 3 antihypertensives.

The study of HTN values in groups based on age decades showed that 5 patients (3.47%) were aged less than 30 years, 51 patients (35.41%) in the 31-40 age group;

46 patients (31.94%) in the 41-50 age group; 34 patients (23.61%) in the 51-60 age group; 8 patients (5.55%) in the 61-70 age group (tab. III).

The study of the role of the genetic risk factor in HTN based on family history showed that 59 study group patients

(40.97%) had no parent with HTN; 62 patients (43.05%) had one parent with HTN and 23 patients (15.98%) had both parents with HTN.

TABLE III
Age distribution of HTN patients

Age groups (years)	No.	%
<30	5	3.47
31-40	51	35.41
41-50	46	31.94
51-60	34	23.61
61-70	8	5.55
Total	144	100.00

Analysis of the prevalence of some categories of risk factors

Smoking. In evaluating smoking patients, we have quantified both the number of cigarettes smoked per day and the smoking duration (in years). Women in the study group, 64 women (44.44%), were mainly non-smokers and of the total number of 80 male patients, only 43 (29.86%) were smokers.

Coffee intake. Coffee intake of one cup per day was seen in 58 patients (40.27%) and 2-3 cups per day in 20 patients (13.88%).

Sedentary lifestyle. It was evaluated based on questioning. The results show that 31 patients (21.52%), mainly women (24; 16.66%) are rather sedentary, as compared to 7 male patients (4.86%) ($p<0.005$). 113 patients (78.47%) were reported as active, but mainly men think of them as active 80 (55.55%), as compared to 33 women (22.92%) ($p\leq 0.05$).

Body mass index (BMI) was calculated by measuring patient's height and weight. By using the formula BMI = weight (kg) / height 2 (m^2), different levels of overweight and obesity, and also the relationship between obesity and HTN stages were assessed in the study group. In this respect, out of the patients with *normal weight* (BMI <25), 12 patients had HTN stage I (all male); 22 patients had HTN stage II (12 male and 10 female); 6 male patients had HTN stage III. Out of the *overweight patients* (BMI = 25-30), 11 patients had HTN stage I (7 male and 4 female), 25 patients had HTN stage II (16 male and 9 female) and 7 men had HTN stage III. In patients with *obesity class I* (BMI = 30-35), 14 patients had HTN stage I (equal male and female ratio), 28 patients had HTN stage II (12 male and 16 female) and 12 patients had HTN stage III. *Obesity class II* (BMI = 35-40) occurred mainly in patients with HTN stage II, while HTN stage I was diagnosed in only 1 woman and HTN stage III in 3 patients. *Obesity class III* (BMI > 40) was found only in 4 of the 144 HTN patients, of whom 3 patients with HTN stage II. Obesity class II and class III was more frequently associated with HTN stage II.

Abdominal perimeter, used as an index that quantifies the distribution of adipose tissue, and abdominal (android) obesity are widely recognized as the most common aspects associated with hypertension and vascular risk. In our study group, abdominal obesity was present in 37 men (25.69%) and 6 women (4.16%) ($p<0.005$). Median risk was correlated with values of

waist circumference ranging between 94 and 102 cm in men and of 80-88 cm in women and it was seen in 24 men (16.66%) and 19 women (13.19%). A high risk (> 102 cm in men and 88 cm in women) of 33 (23.61%) in men and of 22 (15.27%) in women ($p \leq 0.05$) was recorded.

The waist to hip ratio (abdominal-gluteal ratio) (WHR) was calculated by dividing the waist perimeter to the hip perimeter. Android obesity has WHR values higher than 0.8 in women and higher than 0.9 in men. Both men and women in the study group had a higher WHR than normal (43% of men and 29% of women) ($p \leq 0.05$). It was associated mainly with HTN stage II (26% of men and 19% of women) ($p \geq 0.05$).

Fasting blood glucose levels above 110 mg/dl were found in 49 patients (34.02%), of whom 23 (15.97%) were female and 26 (18.05%) were male ($p \geq 0.05$).

Cholesterol levels above 240 mg/dl were found in 83 patients (57.63%), of whom 36 (25.00%) were female and 47 (32.64%) were male ($p \leq 0.05$).

Clinical and epidemiological studies have also shown the presence of HTN risk factors, such as overwork, psychiatric treatments and negative emotions.

Studies of population groups similar to ours have shown risks over large temporal and spatial scales (3, 5, 8, 11).

CONCLUSIONS

Our clinical and epidemiological prospective study, conducted on a representative group of patients seeking care at the family medicine practice has made some contributions by showing the role of modifiable risk factors in the occurrence and outcome of cardiovascular diseases. Thus, it was shown that preventive measures taken to reduce cardiovascular risk under the supervision of the family doctor significantly decrease morbidity and mortality rates.

Clinical and epidemiological surveillance plays an important role in disease prevention, increases the use of ambulatory care and decreases the need for hospital care, with significant economic gains for the individual, the family and the community.

NEWS

SLEEP APNEA AND EMERGENCE OF PNEUMONIA

Sleep apnea is a sleep disorder characterized by obstruction of upper airway which caused hypoxemia, hypercapnia and sleep fragmentation. This disorder is linked with cardiovascular diseases and cognitive impairment. Patients with sleep apnea have an increased risk of pulmonary aspiration and immune perturbations which could facilitate emergence of pneumonia. The link between sleep apnea and pneumonia was evaluated in a cohort study published in *Canadian Medical Association Journal*, conducted by Dr. Vincent Yi-Fong Su and colleagues. This study has a duration of 11 years and followed the emergence of pneumonia in a lot of the 34 100 patients (6816 with sleep apnea and 27 284 controls, with the same comorbidities). The results showed that the patients with sleep apnea had a higher risk to develop pneumonia than the control group (9.36% and 7.77% respectively). For the patients with severe sleep apnea, the risk of pneumonia was higher than the cases with milder severity. Also, the use of continuous positive airway pressure (CPAP) therapy has increased the emergence of pneumonia, the adjusted risk being 1.32 for the cases who received CPAP therapy. The authors showed that sleep apnea is a risk factor for pneumonia (Su VYF, Liu CJ, Wang HK et al. Sleep apnea and risk of pneumonia: a nationwide population-based study. *CMAJ*. 2014 DOI: 10.1503/cmaj.131547).

DENTAL ESTHETICS - INSTRUMENT FOR RECREATING A NEW FACIAL ESTHETIC TO THE ELDERLY PATIENT

Mihaela Monica Scutariu[1], Norina Forna[2]
University of Medicine and Pharmacy "Grigore T. Popa" - Iaşi
Faculty of Dental Medicine
1. Discipline of Oro-dental Diagnosis and Gerontostomatology
2. Department of Implants and Prosthetics

DENTAL ESTHETICS INSTRUMENT FOR RECREATING A NEW FACIAL AESTHETIC TO THE ELDERLY PATIENT (Abstract): **Aims:** The major objective of this paper consists in underlining the wide range of possibilities in assessing the elderly patient; it relies on clinical examination in order to exclusively improve the patient's physiognomic aspect. **Materials and methods:** In this context it has been organized a study which included 64 elderly patients aged between 60 and 90 years of age (median age 75), which presented themselves at the Clinical Service of Dental Semiology and Gerontostomatology between 2011-2012; they requested the restoration of the functions affected by odontal coronary lesions, periodontal disorders or edentations more or less expanded, malocclusions, malrelations of the mandible to the skull and unsuccessful or deteriorated dental or prosthetic treatments. **Results:** The restoration of dental arches has been performed relying on common sense and power of discernment, respecting both facial features and expression by redimensioning the lower part of the face, repositioning the mandible and using gnatoprosthetic devices. **Conclusions:** Solving the problems elderly patients confront themselves with and the success of the treatment has been possible only after a correct assessment of the involutive phenomena that influence the oral cavity, after understanding the local and general factors that predispose to oral disorders as well as the differences between various techniques and materials. **Keywords**: PHYSIOGNOMIC ASPECT, GNAT PROSTHETIC DEVICES, ORAL REHABILITATION, DENTAL ESTHETICS

Humans are social beings. Life within the society has helped them discover the physical, psychical and moral qualities of their fellow men, observe them and establish certain evaluation criteria about good and evil, what is pleasant and unpleasant in the way the people they gets in contact with present themselves. One of these criteria consists in the harmony of human features and their beauty.

Facial physiognomy which is a separate function of the stomatognat system, depends of the morphological configuration of the facial skeleton, the maxillaries, the dental arches and the soft parts which cover the osseous skeleton as well as of the position of the frontal teeth on the arch (1).

The facial aspect is not something static; it varies along with the action of the underlying muscles and the symmetry of their contractions. Under the influence of the orofacial muscles' contractions and of

the muscles that mobilize the mandible during mastication, speech and the other actions these muscles take part at, facial physiognomy experiences, with the passage of time, a continuous transformation (2). Consequently, facial physiognomy has a very well defined role of exteriorizing and communicating emotional conditions and so it represents one of the basic functions of the stomatognat system – the physiognomic function.

The harmony of facial features determined by the morphological configuration and the integrity of the skeleton and of the soft parts, is influenced by the aspect of the dental arches in the frontal region.

The pathological modifications, in such a visible area, can have essential implications on the individual's balance and harmony, leading to negative consequences on his integration in society and inter human relations (3).

Generalized aesthetic modifications are necessary when all anterior teeth are restored and occasionally, the first molars which become visible when the patient smiles. The abnormal morphologic or aesthetic facial balance requires the use of anatomic landmarks and in particular the interincisive papilla which can contribute to the initial assessment of the position of the median line (4).

The dental practitioner can intervene to a great extent in restoring the physiognomic aspect by improving the signs of ageing, providing a maximum support for the facial tissues at ease and while they perform their functions.

The major objective of this paper consists in underlining the wide range of possibilities in assessing the elderly patient and which relies on the clinical examination for exclusively improving the patient's physiognomic aspect.

MATERIAL AND METHODS

The present case study included 64 patients with the age between 60 and 90 years (mean age 75 years) assisted in the Clinical Service of Dental Semiology and Gerontostomatology between 2011-2012 and which required the restoration of the functions disturbed by odonto coronary dental lesions, periodontal affections or edentations, malocclusions, malrelations of the mandible to the skull and unsuccessful or deteriorated dental or prosthetic treatments.

The patients have been examined based on the results of an assessment chart correlating the reasons for which they presented themselves to the dentist with their desires; restoration of the altered physiognomic function requested only in the cases included in the treatments performed.

Facial examination was intended to evaluate the static and dynamic characteristics of the soft muscular-adipose tissues, the skeletal support, the dental arches as well as the relations these structures establish between them; it generates important data which will allow including the result of the treatment into a harmonious ensemble. The facial aspect is also determined by the amount and the quality of the muscular-adipose soft tissues and of the tegument, of their dynamics as well as of the bony structure consisting in the bones of the viscerocranium. The anatomic structures from the level of the face are analyzed as well as the aspect of the integuments, the facial grooves at ease and while smiling.

The relaxation of the muscle groups ensuring the mandible's mobility represents a reference position for facial examination.

The smile consists in the modification

of the physiognomy of the entire face. The wideness of the smile conditions the exposure degree of the dental arches and the area of esthetic interest which must be taken into consideration during the restoration treatment of the dental arches (5).

The smile represents the nonverbal type of communication most often associated to the exposure of dental arches. The position of the oral commissure while smiling determines the number of teeth visible during the action.

The evaluation of the dental arches considering only the esthetic aspect and the introduction of those specific types of treatment which focus only on the appearances can have severe consequences on the future evolution of the dento-maxillary system (6).

The intraoral examination focused on underlining the elements that contribute at altering the physiognomic function: teeth, periodontium, edentated crests, and occlusal relations. Special care has been given to bone reorganization, to the dimensions of the alveolar crests and to the relations between them and to the potentially prosthetic space.

Clinically, the purpose of oral rehabilitation in the case of elderly patients consists in making the dentures look as natural as possible. Consequently, both natural and artificial teeth must be in harmony with the patient's personality, age and sex (7).

RESULTS AND DISCUSSION

The distribution of the patients on age and gender groups indicated a higher frequency of the number of women (men 39-60.93%; women 25-39.07%) and of the age group 65-70 years (fig. 1).

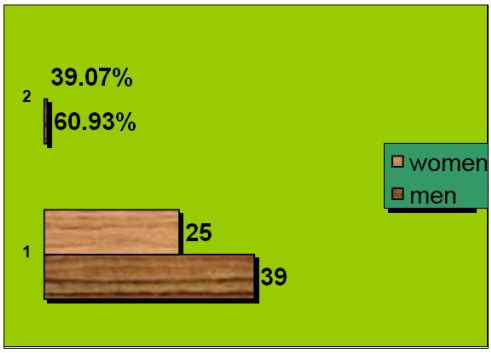

Fig.1. The gender distribution of patients

The distribution of the patients by age groups was as follows (tab. I).

TABLE I

Distribution by age groups

AGE GROUPS (years)	CASES	%
60-65	11	17.18
65-70	16	25.00
70-75	10	15.62
75-80	14	21.87
80-85	9	14.06
85-90	4	6.25

The syndromes recorded were: total edentation – 9 cases (14.06%); subtotal edentation – 10 cases (15.62%); partial edentation – 12 cases (18.75%); odontocoronary lesions – 13 cases (20.32%); parodontopathies – 11 cases (17.18%);

malocclusions – 9 cases (14.07%) (fig. 2).

The medical history indicated the motivation patients had for requesting dental treatment as well as their expectations; it was noticed that the number of women asking for the restoration of the physiognomic function was a lot higher than that of men.

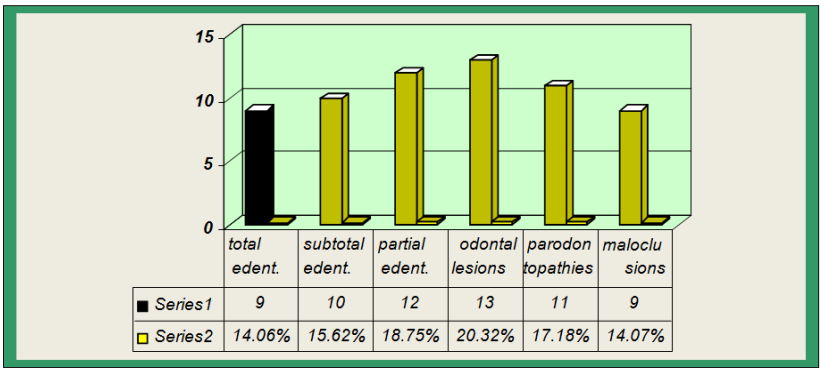

Fig. 2. Distribution of patients by syndromes

In the case of movable patients which benefited of old deteriorated devices or conservatory dental restorations, there have been a number of complaints related to functional unsatisfaction, the material used and the technological approach which lead to physiognomic disorders and needed to be optimized or redone.

The disorders of the stomatognat system with effects on the dental facial esthetics and the attempts of systematizing then according to the anatomical-clinical criteria are mentioned in the work of numerous authors. Thus, in a generic manner, we can say that the physiognomic aspect of the elderly is influenced by odontal and coronary lesions accompanied or not by substance losses, periodontal affections, integrity losses of the arch after edentation and dental migrations, occlusion disorders and by disturbance of the cranial-mandibular relation.

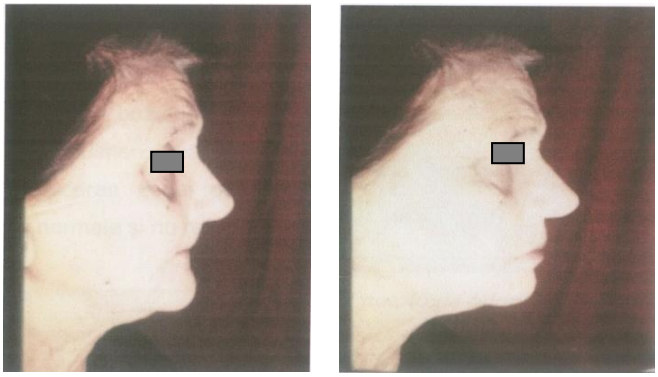
The local clinical examination often pointed out important clinical modifications of the stomatognat system and the prosthetic field, providing us useful information about how to chose and position the frontal teeth, the distribution of edentated spaces, the place of the occlusal plane, about how to model the vestibular crest or margins in removable prosthesis (8).

The low tonicity of the *orbicularis oris* is often noticed at the elderly patients and it is often a clue for the correct positioning of the frontal curvature (9) (fig. 3).

Fig. 3. Low tonicity level of the orbicularis

The facial examination indicates modifications of ageing associated to those due to total edentation at the level of the lips and

the oral cavity, commissures, facial grooves accompanied by asymmetries with under dimension of the lower part of the face and cranial-mandibular malpositions, due to either the loss of the support area or the incorrect prosthesis which does not ensure the normal relations and does not recreate the physiognomic aspect (10) (fig. 4).



a. b.

Fig. 4 a. Modifications characteristic to the ageing process; b. Defective prostheses which do not ensure the normal relations and do not recreate the physiognomic aspect

The intra-oral examination points out the existent oral pathology, in some situations with significant repercussions on the patient's physiognomy. The odontal and periodontal status at the elderly patient is quite heterogenous because of the involutive phenomena and the associated pathology; there are patients with a more or less complete dentition, with odontal coronary lesions, parodontopathies, and malocclusions, partial or total edentations (11).

The examination of the old dentures is also an important clue for the creation of the new dentures if we consider the technology they have been made with and the degree of functional satisfaction.

The restorative treatment focused on reestablishing the physiognomic aspect with composite resins correlating the color, the shape and the dimensions to those of the remaining teeth as an emergency solution and temporization.

In cases of dyschromia, enamel defects, dental usage, diastemata, dental malpossitions, development disorders of the lateral incisors, covering therapy with porcelain – metallic crowns which can combine aesthetic and mechanic qualities. The need of correct porcelain restorations at elderly patients confronts itself with two problems: first of all, each must serve at improving the resistance level and second, it must redo the initial physiognomy (12). The esthetic difficulties determined by the biological support can be corrected with the aid of porcelain bridges.

When talking about dental bridges, we have considered certain particularities in choosing the pillar teeth, the distribution of the potentially prosthetic space (modified because of the migration of the neighboring teeth at level 17 taking over space 16 and resorption of edentated crests) for intermediaries according to certain precise rules.

An excessive loss of the bone or of the frontal periodontal support on limited areas has lead to certain difficulties resulted from the exposure of the interdental spaces accompanied by the widening of the interdental papillary niches, the elongation of the clinical crown and sometimes visibility of the cemento-enamel junction with difficulties in ensuring the proper hygiene and which creates difficulties to the practitioner. The loss of parodontotic teeth with recurrent periapical cyst brings along advanced bony resorption associated to physiognomic disorders.

The use of acrylic appliances has been the temporary solution in these cases accompanied by the simulation of the loss of the gingival tissue, covering the exposed radicular surface, improving the esthetic aspect and preventing food impaction, which is a transitory situation until permanent prostheses.

In the case of the spaces too wide, it was proposed the intervention on the shape accompanied by motion towards the oral of the contact points and pronounced vestibular convexities and chromatic individualization using darker shades which make them narrower; in the case of narrower spaces, a shift of the contacts towards the incisal area and a more flattened morphology give the impression of normal proximal wideness. In case the teeth are much too short (frequent case due to dental usage) the esthetic aspect can be improved by flattening the vestibular side and cervix narrowing. Elongated teeth can be aesthetically corrected through the transformation of proximal contacts into contact surfaces, rounded shapes and false cervices.

When artificial teeth were put on, we have taken into consideration that the upper and lower incisors must not be in contact in the centric relation, without allowing the possibility for an anterior movement of at least 1 mm and an angle of at least 15° in protrusive occlusion which leads to the necessity of correlating overbite and over jet.

The restoration of dental arches has been performed with a lot of common sense and power of discernment, respecting both character and facial expression by redimensioning the lower part of the face, repositioning the mandible and using gnatoprosthetic appliances.

The aesthetic aspect has always been a matter of sensitivity regardless of the numerous norms and indications, hence, regardless of the patient's age; the purpose of restoration is that of obtaining aesthetically acceptable results (13). During the restoration process of the physiognomic function, the prosthetic variants took into consideration the type of edentation and the condition of the muco-osseous and dento-periodontal support.

It was noticed that the loss of teeth has affected the relative balance from the ageing process transforming ageing from a harmonious process into a disharmonious one. The multiple therapeutic possibilities for restoring the elder patient's physiognomy foreseen by modern dentistry are still limited by the patient's common sense and also by his financial possibilities (14).

Thus, it appears the problem of identifying a solution that is financially convenient for the patient and which ensures at the same time the complete functionality and esthetics specific to the restoration process.

Odontal and prosthetic treatments provide multiple possibilities for reestablishing the functions of the stomatognat system, of the physiognomic aspect which is influenced by both oral pathology and involutive process.

Nonetheless the elder patient can be helped in regaining his self confidence by reestablishing his physiognomic aspect, this must not be always more important than the other basic principles of dental practice. Regaining the physiognomic function of the stomatognat system by improving the gnatoprosthetic appliances represents an essential area of interest for the contemporary dentistry (15, 16) (fig. 5).

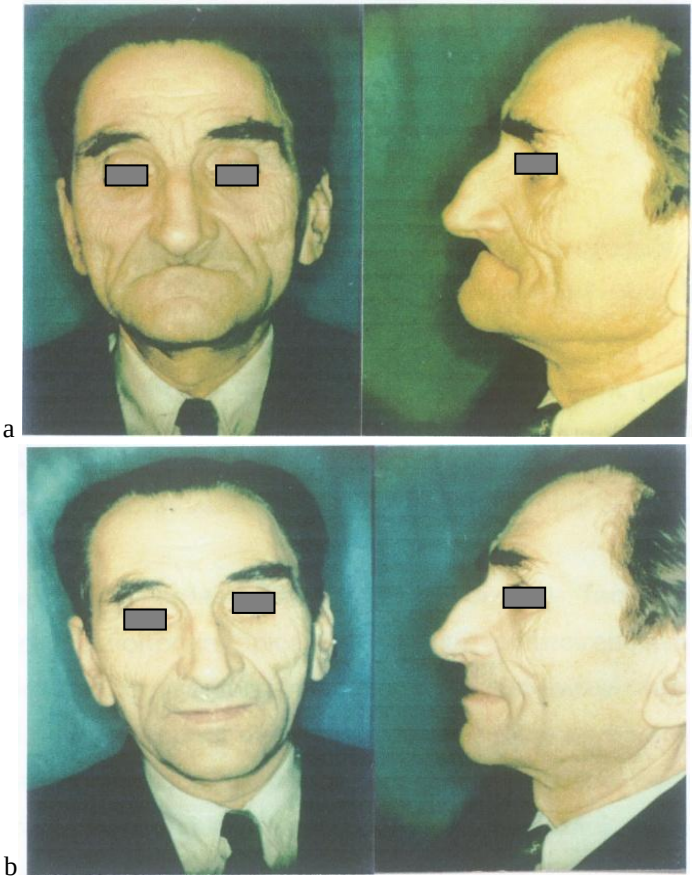


Fig. 5. a. Faces characteristic to a totally bimaxillary edentated person
b. Reestablishing the individualized physiognomic function

Considering all that was previously stated, as well as the high number of the elderly affected and which are every time more interested in their aspect, our main mission consisted in the possibility of improving their disharmonious ageing process by replacing their local infirmity and thus, improving the quality of their lives.

Esthetics at the elderly patient, in the contemporary dentistry, relies on an interdisciplinary collaboration based on a complex and complete medical analysis, subordinated at its turn to the concept of total oral rehabilitation. In this concept, we can reiterate what Goldstain stated, that "den-

tofacial esthetics represents the art of dentistry in its purest form".

CONCLUSIONS

Solving the problems of the elderly and the success of the treatments can only be reached after a correct assessment of the involutive phenomena which influence the oral environment, after understanding and knowing the local and general factors which predispose to oral disorders as well as the different techniques and materials.

The main objective that must guide our every therapeutic attempt must always consider the introduction of teeth into the general picture of facial structures, in a manner as efficient as possible so to not underline even more the infirmity that appeared due to an altered odontal, periodontal or arch integrity.

Department of Preventive Dentistry

OCCUPATIONAL HEALTH PROBLEMS AMONG DENTISTS IN MOLDAVIAN REGION OF ROMANIA (Abstract): **Aim**: The aim of this study was to evaluate the occupational health problems among dentists in the Moldavian Region of Romania**. Material and methods**: Questionnaire-based study was conducted on 152 dentists aged between 25-65 years practicing in 6 counties the Moldavian Region of Romania. The questionnaire included questions related to the dentists' occupational health pathology. Data were statistically analyzed using *SPSS 14.0* and chi-square test ($p<0.05$). **Results**: The majority of the dentists (91%) consider that they are exposed to an occupational risk and 41.8% of them experienced a percutaneus injury caused by sharp instruments in the last year.74.6% of the dentists are protected by vaccination against hepatitis B and 76.1% against influenza. 49.3% of the dentists reported eye injuries caused by solid particles (13.2%), blood splashes (14.7%) and/or chemicals (20,5%). Allergies associated to professional activity were reported by 76.1% of the dentists. **Conclusions**: The dental staff must be informed in order to recognize, control and prevent the potential occupational hazards in the workplace. **Keywords**: OCCUPATIONAL HEALTH, DENTISTS, PREVENTION

Occupational health of the medical staff in the dental office is of particular concern in order to reduce exposures to risk factors as percutaneous injures, exposures to airborne pathogens, contact with materials and chemicals, ergonomic hazards, noise, vibration, radiations, eye injuries, allergens, stress (1). Most of the occupational exposures can be prevented by applying the concept of Standard Precautions during the clinical activity in the dental office (2).

MATERIAL AND METHODS

In order to assess dentists'occupational health problems in Moldavian Region of Romania a questionnaire-based study was conducted involving 268 dentists, 72.7% women and 27.3% men, aged between 25 and 65 years, working at private dental offices in 6 counties of Moldova: Iasi, Botosani, Neamt, Suceava, Bacau and Vaslui.

The questionnaire included 21 questions on the occupational health problems reported by the dentists related to exposures by sharp instruments, musculoskeletal disorders, and ergonomic position during clinical activity, vision and hearing problems, exposure to vibration, allergies, exposure to stressful situations.

Data were processed using *SPSS 14.0* system and compared using Chi-square test

($p<0.05$). The approval of the Ethics Committee of the "Gr.T.Popa" University of Medicine and Pharmacy Iasi was obtained.

RESULTS

91% of the dentists consider that they are exposed to an occupational risk during the clinical activity. From those 22.2% mentioned the risk of contamination with pathogenic agents.

During the professional activity 41.8% of the subjects experienced a percutaneus injury caused by sharp instruments in the last year (fig.1).

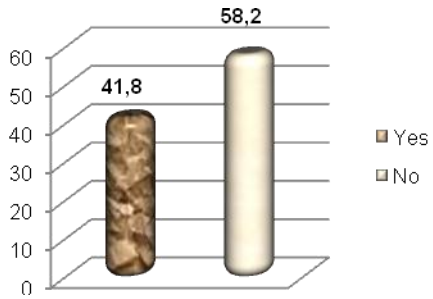

Fig. 1. Prevalence of dentists' percutaneus exposures during the last year

From the exposed dentists 10.4% reported the incident to a specialist in occupational health in order to follow an appropriate post-exposure protocol. 74.6% of the dentists are protected by vaccination against hepatitis B and 76.1% against influenza.

The number of hours spent daily by the dentists at work ranges between 1-4 hours (34.9%), 4-7 hours (51.2%) and over 7 hours (34.9%).

49.3% of the dentists reported eye injuries caused by solid particles (13.2%), blood splashes (14.7%) and/or chemicals (20.5%) (fig.2). Protection goggles are used by 72.4% of the respondents.

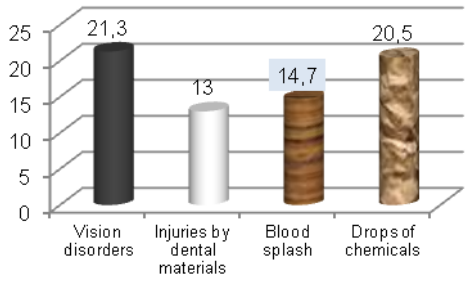

Fig. 2. Factors related to dentists' ocular health

The musculoskeletal disorders were reported by 70.1% of the subjects. The most frequent symptom was the pain located in the cervical spine (47.3%), lumbar spine (36.7%), dominant arm (43.1%) and hip (10.4%) (fig.3). Other mentioned musculoskeletal symptoms were: muscular spasm (28.3%), paresthesia (15.8%) and functional limitation (27.1%).

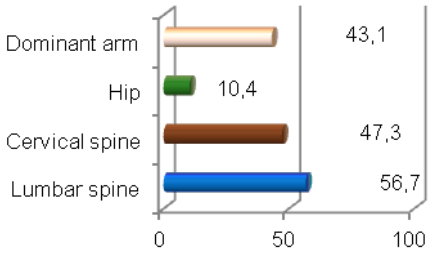

Fig.3. Dentists' occupational musculoskeletal pain localization.

Allergies associated to professional activity were reported by 76.1% of the dentists. The most incriminated allergens were the latex protective gloves (13.4%) and the impression materials (8.8%) (fig. 4).

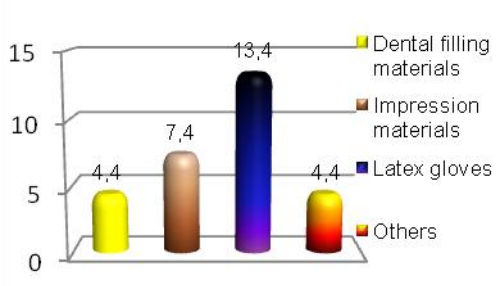

Fig.4. Allergens associated to dentists' occupational pathology

The mental illnesses associated to the professional activity reported by the subjects were: depression (5.9%), alimentation problems (5.8%) and anxiety (1.4%).

The self- reported professional stress is rated by most dentists in the 5 (22.4%) and 7 (20.9%) level on a scale between 1 and 10.

29.9% of the dentists are smokers but this habit is not considered as a work-related one.

DISCUSSION

The modern dentistry has advanced with giant steps but it is still associated with important occupational risks for the dental team. Extensive literature reviews reveal the hazards represented by percutaneous exposures, eye injuries, noise, vibration, ergonomic factors, contact with allergens and toxic chemicals, stress.

Dental personnel can be exposed to pathogenic microorganisms including staphylococci, streptococci, cytomegalovirus, HBV, HCV, herpes simplex virus, HIV, *Mycobacterium tuberculosis* and other viruses and bacteria from the oral cavity and respiratory tract. These pathogens can be transmitted through direct contact with blood or other contaminated fluids, indirect contact with contaminated instruments, equipment or environmental surfaces, contact of nasal, conjunctive or oral mucosa with droplets and inhalation of airborne microorganisms (3).

In our study most dentists consider that they are exposed to occupational risk factors from which the most important is represented by exposure to blood through incidents caused by needle stick and sharps instruments. About half of all dentists reported such an exposure during the last year. The prevalence of sharps injuries reported in literature reviews is about 50% in United Kingdom and Thailand, 28% in Queensland Australia, 138% in Durban South Africa (4, 5, 6, 7).

From the exposed dentists only ten percent reported the incident to a specialist in occupational health demonstrating a poor knowledge regarding the post-exposure protocol which must be followed in order to decrease the risk of diseases transmission. Prevention of percutaneous exposures must be achieved by dental team education, immunization, and use of protective equipment and safety devices. Even although the dentists are concerned about the possible transmission of blood borne pathogens like hepatitis B virus, hepatitis C virus or HIV only 74.6% of them are vaccinated against hepatitis B.

The eye problems associated to the dentists' professional activity refer to injures caused by fragments of dental filling materials, dental tissues, calculus or metal, blood splashes or chemical drops. The prevalence of the ocular problems reported in the literature range between 10% and 73% (8, 9). The eye injuries have a high risk of infection and can affect the professional performance of the dentist. Even though dentists' eye protection is highly recommended only 72.4% of the respondents in our study use goggles

or face shields.

Another important risk factor is represented by the contact with allergens like latex gloves, dental filling materials, impression materials, chemicals, anesthetic gasses, disinfectants. In our study three quarters of the respondents reported allergic reactions, especially in the form of dermatitis caused by latex gloves.

Musculoskeletal disorders represent one of the most serious occupational pathology hazards. Three quarters of the dentists in our study declare to suffer symptoms, especially pain, located in the spine and dominant arm. Our results on lumbar pain are comparable with those, reported by other authors: 50.0% Al Wazzan, 55.2% Ratzon, 54.3% Legat, 52.2% Barlean, 54.2% Gibels (10, 11, 12, 13, 14).

Dentistry is considered one of the more stressful medical specialties due to specific factors like physical strain, patients' pain and anxiety, treatment compliance, competition, isolation, monotony, lack of appreciation, economic pressures or seeking ideal results. Our results illustrate a low prevalence of the mental disorders compared with that reported by other researchers. In Lituania 95.7% of the dentists suffered psychological problems associated to professional stress, sleep disorders -78.8%, tension- 80.5% and anxiety- 96.4% (15). In Great Britain 60% per cent of dentists reported being nervy, tense or depressed, 58.3% reported headache, 60% reported difficulty in sleeping and 48.2% reported feeling tired for no apparent reason related to work stress (16). In order to decrease those harmful effects dentists must identify the stressors, apply appropriate stress management strategies and to adopt healthy habits and attitudes**.**

CONCLUSIONS

Exposure to numerous biological, chemical, environmental, physical, and psychological risk factors is highly associated with the clinical activity in the dental office. The dental staff must be informed and educated in order to recognize, control and prevent the potential occupational hazards in the workplace.

CELL THERAPY IN BISPHOSPHONATE-RELATED OSTEONECROSIS OF THE JAW

Bisphosphonate-related osteonecrosis of the jaw is a clinical condition found in patients who have received intravenous or oral bisphosphonate therapy for various diseases related to bone. This report describes an innovative aproach for the treatment of this condition using autologous bone marrow stem cells, platelet-rich plasma, beta tricalcium phosphate, and demineralized bone matrix. The patient was a 71-year-old woman with history of multiple myeloma treated with intravenous zoledronic acid during 4 years. After a tooth extraction, the patient presented with a painful bisphosphonate-related osteonecrosis lesion with no healing wound and cortical bone exposure. The patient was surgically managed with a standardized protocol of autologous stem cell therapy combining bone marrow harvest, cell concentration procedures, and intraoral surgery. CT scan performed 6 months later showed improvement of bone and concentric ossification. The authors concluded that cellular therapy might be considered a new strategy to heal bisphosphonate-related osteonecrosis of the jaw lesions [Gonzálvez-García M, Rodríguez-Lozano FJ, Villanueva V, Segarra-Fenoll D, Rodríguez-González MA, Oñate-Sánchez R, Blanquer M,Moraleda JM. Cell therapy in bisphosphonate-related osteonecrosis of the jaw. *J Craniofac Surg* 2013; 24(3): 226-228].

THE THIRD AGE–A CURRENT ISSUE FOR THE FAMILY PHYSICIAN (Abstract): Since our birth, we are programmed to experience predetermined stages of life whose passage is inevitable as the passage of time (childhood, youth, adulthood, old age). Although each of these stages of development differs in its specific tasks, the old age seems to be the most burdensome, resulting in significant changes: physical and intellectual decline, major changes in the importance of the professional, marital, parental and social role. One of the main indicators of the quality of life, the average life expectancy increased significantly in the last 3-4 decades and the mankind gained decades of active life in a relatively short period of time. Therefore, one of the goals of medicine has become the prolongation of life, the pursuit of old age, the wish to remain healthy, to be able of physical and intellectual performance and useful in the private and social life. The old age is conditioned by a complex combination of factors: the individual genetic predisposition, the lifestyle of society and the environment, all of which affect the opinions regarding health and subsequently the attitude towards health. The family physician has the social obligation to research and promote health, to fight diseases. The family physician achieves this by researching the aging field and by trying to find solutions to improve the quality of life in the elderly, which is a prerequisite of maintaining the integration of the elderly into family life and society, of preserving the biological and social independence of aged persons. The maintenance of an active private and social life is a method of fighting premature aging associated with infirmity and disease. This action cannot be successful without the active involvement of the elderly and without their acceptance in the society. Aging is a biological process that affects the entire body, following the period of development and it is considered the final stage of biomorphosis. **Keywords**: AGING-ASSOCIATED DISEASES, AGING MECHANISMS, VULNERABILITY, DEPENDENCY, QUALITY OF LIFE.

Many centuries ago, it was considered that medicine should accomplish the following duties: to preserve health, to cure diseases and to prolong life. This latter objective was achieved not only through the use of biomedical sciences, but also due to better socioeconomic conditions.

It is believed that the successful eradication of mortality from cardiovascular disease and cancer would lead to an increased life expectancy (1, 2). Even so, the maximum limits of human survival phenomenon would be not influenced. To achieve this goal it would be necessary to

"break" certain specific genetic barriers.

The efforts to extend the natural limits of life cover the following targets: the deciphering the human genetic code, the discovery of the mechanism of transmission of hereditary characteristics, genetic engineering and so on. This could reveal a deeper understanding of the phenomenon of life. The scientific progress in this field brings an exaggerated enthusiasm, manifested through extremely optimistic assumptions that are often unjustified. The exact mechanism by which the human body is aging is not understood (2). Some theories suggest the damage caused by ultraviolet radiation and the body wear induced by end products of metabolism. Other theories claim that aging is a predetermined genetically controlled process.

Gerontology defines aging as a cumulative effect of body interactions with various factors throughout life (3, 6). These factors are represented by environment, cultural influences, dietary behaviors, physical exercise, leisure, diseases, etc.

It has been shown that aging is not caused by the action of a hormone or of a "suicide gene", which at some point may become active. Aging is rather a very complex phenomenon. Life span is "rigid", as it varies within small limits in the same species. Human life expectancy is substantially reduced compared to the biological, genetically determined life expectancy which is characteristic for the human species, but not due to the evolution of the physiological aging process carried to the last vital human resources, but due to aging-associated diseases, chronic and degenerative pathology. The prevention and treatment of cardiovascular diseases and cancer are still not possible without the progress in understanding the mechanisms of aging and the correlations between aging and associated pathology (1,2).

The contribution itself of elderly persons is not of less importance. The main issue is to "be able to grow old" and "to learn to grow old", because nowadays the term geragogy is used to denominate an appropriate pedagogy of this stage of life. Aging means first of all the edification of a way of thinking. Nowadays aging is seen as a universal biological phenomenon, which is basically a natural physiological process and not a morbid one. The idea of old age as a disease belongs to the history of concepts about aging (4, 9). This should be seen not as a drama, as a catastrophe, but as the last stage of life with its advantages and disadvantages, as any other stage of life. The changes seen in the aging process affect the clinical picture of some diseases and represent sometimes an impediment to gathering data, in making a diagnosis, a prognosis and a treatment schema. Aging is the progressive and irreversible alteration of body functions which cannot be eliminated and causes a greater vulnerability of the individual. The term “vulnerability” or “fragility” was introduced in the medical language in the last decade of the last century (5, 14).

With the passage of time, biological aging occurs and changes in all organs are seen. The damage to a body system brings damage to another and consequently vulnerability. An autonomous person may become deeply dependent and may evolve to a syndrome of renunciation leading to a fatal end.

Aging should not be necessarily identified with diseases, even if during old age illness may be more common. Aging should also not be identified with decline, because even if some functions and skills may regress, other can be maintained until old age, and some can even improve. Phys-

ical abilities decrease progressively. The adaptability to changes diminishes, but it can be enhanced through self-education. However, intellectual functions are not affected by aging and their results are similar to those in young people and adults. The elderly maintain their ability to learn (2).Therefore human beings can change their life expectancy, by increasing it or, unfortunately, often by shortening it.

SIGNIFICANCE OF GERIATRICS AND GERONTOLOGY

Geriatrics is a branch of medical science dealing with prevention and treatment of diseases in the elderly (6, 7) and gerontology studies the human aging process from the point of view of physiological doctrines and, later, in the context of biology and medicine (6, 8).

The long-term observations provided information about the social life of elderly, about the old age as the age of wisdom, as the age of outcomes, which brings peace with others and a gradual detachment from the hot matters of the world.

Gerontology includes four aspects, as follows: the social, economic, psychological, physiological and pathological aspect. They affect the aging process and the research studies each of these aspects in order to prolong the life and to revive the years (8).

Ageing has always fascinated mankind. The increasing average age of the population is the result of socio-economic development: the improvement of nutrition, housing, education and hygiene of the population, especially in developed countries (9). In developing countries, there is a high mortality, resulting in a lower average age.

It is generally admitted that a mature person is likely to reach an old age, according to his genetic heritage. A distinction is made between the primary aging, which is determined by genes, and secondary aging, which depends on environmental factors (10).

Most of the elderly do not realize that they will have the opportunity to practice the activities that they have dreamed of during the retirement period, a period which in some cases has a negative impact on the life of the aged persons. The mood of the elderly is an important aspect of the quality of life. The aged persons with poor health are more vulnerable, more dependent, and show a much stronger need to stay with their families. Although family support is considered the most important and most appropriate "form of care" for the elderly, for independent reasons, the family is put in the situation to dedicate less and less time and to provide insufficient support to grandparents / parents. In such cases, the elderly become in permanent or temporary need of a personal assistant. However, it is not uncommon for a family with different generations to encounter difficulties in adapting to the new roles imposed by growing old (10, 11).

Cessation of employment, the decreased freedom of movement, diseases and even death affecting people in the circle of friends lead to a major decrease in the social status of the aged persons. This brings a sense of loneliness and isolation.

There are cases when the family helps older people to achieve a better life and to maintain their autonomy for as long as possible. Disturbed families condemn elderly persons to dependence for social reasons, but also by use of violence and abuse, which result in disabling medical conditions. On the other hand, the lack of any family is a precipitating factor of vulnerability and dependence (12).

The aged patients often experience con-

fusing and difficult situations, resulting in a conflict between the desire to be useful to the family and the need for support, care and attention from the loved ones. Some old persons feel like they are a burden to the family and prefer to live alone or in nursing homes and to suffer all the consequences that these choices bring in their lives. Factors leading to loss of autonomy and hence to a higher level of dependence are mainly medical and social. Medical factors are represented by diseases of various body systems that lead to a certain degree of disability. Social factors include the lack of housing and proper financial assistance. Housing is an important indicator of the comfort of human life and it is of major importance for the elderly, who are vulnerable and have special needs.

The elderly experience many difficulties and aging itself is not a disease, but the clinician takes into account the physiological performance of the patient by correlating them with age, in order to develop post-disease rehabilitation programs (13,14). Optimal medical and social care of the elderly brings high costs for families and communities.

Mood is an important indicator of the quality of life. Sadness is common in elderly and it is sometimes associated with depression. Loneliness is sad reality of most aged people and may be associated with vulnerability (15, 16).

MORPHOLOGICAL AND PHYSIOLOGICAL CHANGES OF AGING

Old age is a period of profound deterioration and involution of the main functions of the human body. The normal signs of aging are generally the same for all people, although they do not necessarily occur at a certain age. Each person has its own pace of aging, dependent on genetic factors and lifestyle.

One of the most significant indicators of the quality of life in the elderly is the health status.

A poor health status leads to a higher risk of autonomy loss. Some persons can grow very old and maintain a high degree of autonomy just because they have succeeded to keep healthy. But health status is influenced by many factors, so that the individual, the family and the society have to ensure optimum conditions since young age (14, 15).

Aging is a continuous gradual process that begins at birth and continues throughout all stages of life, until old age, when most body functions decline. An autonomous person can become deeply dependent and evolve to a fatal outcome. In order to describe this chain of events, the domino theory was used, a metaphor which describes the propagation of diseases as a succession of falling domino pieces (14, 16).

The aged person represents a "deposit of morbidity" which was accumulated throughout life. Therefore the elderly need diversified and specialized care that combines medical and social aspects. Over the years, the physical decline is felt more intensely. The general process of aging is unique to each person and diseases occur depending on individual sensitivity. Among the most common aging-associated diseases are: cardiovascular diseases (hypertension, coronary heart disease, and stroke), diseases of the musculoskeletal system (arthritis, osteoporosis), sensorial changes (hearing and visual disabilities), and dementias.

Changes occur gradually in all parts and organs of the body (8). The biological aging is caused by changes in various organs and systems, but, in the elderly, some events occurring in life accelerates the

aging. Therefore the aging can often be accompanied by an increased vulnerability to psychological disorders, which is called psychological aging (15). According to E. Erikson's theory, (cited by Bocsa), the last period of life is a continuing effort to preserve the integrity, but each aged person experiences differently life events, according to his previous life experience, economic status and social interactions (11).

Physical decline increases in the course of time, the overall appearance of the skin changes, the percentage of body water decreases, muscle atrophies occur, the physical capacity decreases, the number of neurons in the central nervous system decreases, various dysmetabolic conditions exacerbate (diabetes, liver diseases, kidney diseases or pancreatic diseases), hypoxia may occur due to the cardiovascular pathology or to the use of toxic substances (alcohol, drugs), leading to the insufficient oxygenation of the brain. The aging process varies with each person, depending on the individual sensitivity to certain diseases.

The psychological aging, caused by disturbing events, represents an increased vulnerability to psychological mood shifts (15, 16).

Mental decline manifests itself at a cognitive, affective and behavioral level. Cognitive changes are among the most important medical conditions of aging, with a great impact on the quality of life and entourage. The elderly experience quite often negative feelings. Sadness, anxiety, concerns are considered normal in any effort to adapt. Elderly limit their activities because of physical impairment, which reduces physical capacity and mobility, their field of interest and hobbies narrows, focusing mainly on certain areas, which are improved and deepened. Changes are either rejected or accepted with high anxiety (17,18).

Retirement often coincides with the end of working life. People who work in areas that allow activity after official retirement are the exception to the rule. The abandonment of the ritual of work is sometimes seen as a positive experience, as an opportunity for fulfillment of desires for which there was never enough time, as well deserved moment of rest after long years of work. There may be also feelings of uselessness, the need to rethink the meaning of one's own existence and to discovery of new sources of satisfaction. A negative factor is the decrease of income, especially in the present socioeconomic situation, when retired people represent a socially disadvantaged class. The decreased freedom of movement, diseases and even death affecting people in the circle of friends, the sense of loneliness and isolation are also a negative aspect of the old age.

The *physiological aging* affects differently the organs and the aging process itself may have develop differently, depending on the correlation between biological and chronological age (10). The physiological aging can be gradually seen in the osteomuscular system (decreased muscle strength and lower physical capacity, slower and shorter walking, reduced hand movements, stooped position and height reduction, the reduction of the articular cartilages, bone rarefaction and reduced bone mass, limitation of joint movements), in the cardio respiratory system (reduced vital capacity; lower thoracic movements, slow heart rate, increased systolic blood pressure and decreased diastolic blood pressure, poor response to increased heart activity), in the gastrointestinal and genitourinary system (delayed bowel function, decreased secretion of digestive enzymes, gastric hypoacidity, slow filling of the stomach; reduced filtering capacity of the kidneys, increased

prostate volume), in the nervous system (brain cell atrophy, slowing reflexes).

The *psycho-physiological aging* refers to physiological aging associated with pathological processes, as a result of the action upon the body of external and internal environmental factors that change the normal aging process in a biostructural context, such as: internal factors (heredity, wear, the mental life), external factors (ecological, socio professional, socio cultural, relational factors).

The *sensory senescence* affects the sight (loss of elasticity of the lens, significantly reducing visual field, that leads to deterioration of image quality, of visual habituation and to decreased lacrimation), the hearing (decreased auditory sensitivity, decreased phonemic awareness), the touch (decreased tactile sensitivity), the smell and the taste (are less affected, but the nose becomes prominent; dry mouth, reduced saliva and reducing taste buds can be seen), the attention (voluntary attention and focus decrease mostly, leading to decreased memnotic and cognitive capacity), the memory (low short term memory and preservation of the long-term memory, leading to difficulties in assessing chronological events and to impaired temporal-spatial orientation), the thinking (decrease of ideation, spontaneity, flexibility of thought, favoring rigidity and inflexibility, increased frequency of stereotypes, difficulty in rapidly adapting, a greater conservation or development of synthesis, generalization and schematization capacities, which leads to a greater reflexivity, circumspection, temperance, contemplation), the language (decreased verbal flow, slow rhythm of speech and vocabulary achievement, weakening voice -phonasthenia), the affectivity (is predominantly negative and manifests itself as depression, apathy, reduced emotional resonance), the emotional behavior (irritability, emotional lability), the instinctual behavior (dominated by the changes in sexuality, with reduced sexual activity, reduced endocrine support, but not accompanied by a proportional decrease in eroticism and libidinal tension) (9).

All these changes require network of social support as extended as possible, made up of family members and of former colleagues, friends and acquaintances, as a result of recognition of self-worth.

Besides biological and psychological aging there is a social aging because unfortunately old age is associated by most people with disease, weakness, conservatism, lack of judgment, irritability and dependence on others. The elderly are often treated with contempt and the fact that they valuable to the society is ignored (17).

Ageing beautifully is conditioned by a good biological and psychological state and is the result of an accumulation of genetic factors, of character traits, of autobiographical data. An active attitude towards life, adopting and maintaining a healthy lifestyle, with conscious involvement in well organized activities of interest are essential for a happy old age.

SOME RECOMMENDATIONS FOR AGING BEAUTIFULLY

The secret of healthy aging and physical independence is the regular physical activity. The body remains strong through physical exercise, which protects and improves the emotional and cognitive state. In aged persons suffering from a chronic disease, physical activity can reduce the need for medication used to control or treat the disease in question.

Mental and emotional vitality are closely related to the physical one. The thought has a powerful effect on the body and the

physical well-being affects the emotion and thought. Social relations play also a beneficial role. The emotional and cognitive health status can improve through regular physical activity, which produces certain substances that generate well-being. On the other hand, inactivity can exacerbate depression, anxiety and stress.

Emotional health can be protected or improved by maintaining the interaction with friends, family and community (1, 9, 15). Memory and intelligence can improve or maintain by means of daily intellectual stimulation, but also using repetition and routine. It is necessary to avoid stress, that has possible adverse effects on mental state and positive thinking can prolong life. A proper diet maintains the good functioning of the body. In older ages, the balance of the body can deteriorate and lead to diseases that make the elderly even more fragile.

It is necessary for every individual to be actively involved in decision making on his own health, to learn more about themselves and to properly manage the personal medical information, that includes treatment schemes, medical care, physical exams, screening tests and recommended vaccinations.

CONCLUSIONS

Harmonious aging depends strongly on the opinion and also on the relationship between elderly and younger people.

The most important thing to do for the elderly, as a reward for what they have succeeded to pass on to the younger generations is to show understanding, patience and civility, to overlook their impulsive behavior and to give them confidence and the feeling of usefulness.

Their experience and wisdom can always help and it represents a resource to be exploited.

Healthy individuals with a healthy lifestyle can delay or prevent many aging-related diseases.

In people with chronic diseases or disabilities, the rehabilitation exercises may have a positive effect on physical and mental health. Regardless of the moment when a healthy behavior was adopted, this behavior improves the quality of life and may increase life expectancy.

Ageing beautifully, in a good biological and psychological state, may be the result of an accumulation of genetic factors, of character traits and of autobiographical data, but an active attitude towards life, adopting and maintaining a healthy lifestyle, with conscious involvement in well organized activities of interest at an individual, family and community level are also important.

Understanding the needs of the elderly, both healthy and sick, is one of the most important ethical issues. It concerns the society, the family and especially the family physician.

NEWS

EFFECT OF PERIODONTAL DISEASE ON DIABETS

Periodontal diseases, including the reversible form gingivitis, affect up to 90% of the world's population. Periodontitis is reported to affect half of adults or more with the severe form periodontitis affecting around 10% (range: 5–20%) of adults and moderate periodontitis affecting around one-third. In aged populations the prevalence of periodontitis is even higher: It is reported that 70–90% of individuals aged 60–74 years suffer from periodontitis. It is estimated that 346 million people have diabetes worldwide with the prediction of 439 million by the year 2030, representing an increase of 54% in 20 years to encompass almost one tenth of adults 20 years and older. Currently, there is increasing interest in links between periodontal disease and non-oral, systemic, inflammatory-related diseases and conditions, such as atherosclerotic cerebro-cardiovascular conditions and events. The biologic plausibility supporting such connection is based on the fact that inflammatory periodontal disease due to reaction to pathogenic biofilm stimulates a chronic systemic inflammation and thus contributes to the cumulative inflammatory burden in the host. Inflammation precedes diabetes onset and is linked to insulin resistance and development of diabetes as well as its complications. Since effective therapy and management of periodontal disease are well established, it is important to know for future prevention and control of diabetes whether periodontitis indeed plays a role in the development and control of diabetes and its potentially fatal complications.If such a causal relation indeed exists, a new paradigm in dental and medical standard of care for screening, prevention and management of diabetes could be developed in the future. Close collaboration among each patient's health care professionals would be warranted, especially among medical and dental care providers (Effect of periodontal disease on diabetes: systematic review of epidemiologic observational evidence. *Periodontol 2013;84(4 Suppl.):S135-S152).*

CURRENT ISSUES IN GASTRIC CANCER EPIDEMIOLOGY (Abstract): Gastric cancer, one of the most common malignant tumors of digestive tract continues to be a major health problem by frequency, aggressiveness and low rate of cure in symptomatic stage. Although its incidence is decreasing (especially in the West), globally the gastric cancer is ranked fourth in incidence among cancers at various sites. Despite these developments, the gastric cancer mortality, overall declining globally, is high, especially in the West where even if diagnosed fewer cases of gastric cancer, TNM stages are advanced and have a poor prognosis. In contrast, in Japan, where the incidence is still high, the percentage of cases diagnosed at the stage of "early gastric cancer" has greatly increased, thus improving prognosis. Gastric neoplasia affects more men, age range 50-70 years, disadvantaged social classes and black race. In Romania the gastric cancer incidence is increasing over recent years, presenting variations across the country being more common in men compared with women, reaching a peak of incidence around age 60. Gastric cancer mortality in the world places Romania among the countries with average mortality. Gastric cancer prognosis remains extremely reserved, in close correlation with tumor stage at diagnosis, surgical treatment being the only possibility to provide improved survival, especially in the early stages. Improvement of survival rate in recent years is due to increased gastric resectability result of an earlier diagnosis, a more complex treatment and a closer monitoring of the population at risk. **Keywords**: GASTRIC CANCER, INCIDENCE, MORTALITY

Gastric cancer still remains one of the most common malignant tumors of digestive tract responsible for a mortality which remains high (1). Adeno-carcinoma accounts for over 95% of malignant gastric tumors tract, that is why the generic name of gastric cancer refers, in most cases, to adenocarcinoma, other gastric tumors (lymphoma, stromal tumors, sarcoma, carcinoid) being very rare (2, 3). Both main locations of gastric adenocarcinoma are proximal (cardial) and distal (noncardial).

Despite the decline of distal gastric cancer, the incidence of proximal tumors increased continuously since 1970 (4). These types of gastric tumors are prevalent in populations of different geographical regions, different races and from different socio-economic groups. There may also be differences in the genetic susceptibility, disease profile, clinicalmanifestations and prognosis, the differences related to differ-

ent locations of gastric cancer suggesting the hypothesis that they are distinct diseases with different pathologies (5).

Epidemiologically gastric cancer has two distinguishing features: variability of incidence and mortality rates in different countries and geographical areas and the downward trend of these indicators.

GEOGRAPHICAL VARIATIONSOF GASTRIC CANCER

In 2008, 988,000 people worldwide were diagnosed with gastric cancer, international incidence having wide variations. The highest incidence rate is recorded in East Asia (China, Japan, Korea, Mongolia), the rate being estimated at 42 cases per 100,000 masculine gender persons and 18 new cases per 100,000 women. A high incidence is recorded in Eastern Europe and South America, with more than 20 new cases per 100,000 men and 9 cases per 100,000 women. The lowest incidence is estimated in North and South Africa (6).

Difference in gastric cancer incidence and mortality is not only recorded in an international context, but also within the same country. In Japan, the gastric cancer remains the most common type of cancer in both men and women, the incidence of gastric cancer being the highest (100 cases per 100,000 inhabitants), here this neoplasia being the first cause of death (6). The high incidence of this disease in Japan has led to the development of efficient programs for early detection of gastric cancer. In Japan, gastric cancer is more common in northern areas (Miyagi) than the south (Fu Knoka). Distal tumors predominate in Japan contrasting with an increased incidence of proximal tumors in Western countries, although here in recent years, there has been an increase in the proportion of proximal gastric cancers. In the U.S. the decline of incidence was dramatic, gastric cancer becoming the 14th leading cause of death each year being estimated at 21,900 new cases per year and 13,500 deaths per year (7). Also, the same unevenness in the distribution of the disease is reported by American authors, the highest rates of mortality from gastric cancer being recorded in the northern states: Iowa, Michigan, New York, Connecticut compared to Georgia, Louisiana in the southern of United States (8). In 2008, the European Union has reported 83,000 new cases of gastric cancer, the incidence being of 18.9 new cases at 100,000 inhabitants per year, with rates 1.5 times higher in males with the top of incidence in the seventh decade of life. The highest rate of incidence was registered at Lithuanian men and Estonian women and the lowest in Sweden, an average incidence being registered in the UK (9).

The multicentre study conducted in Romania in 2003 by the Romanian Society of Digestive Endoscopy, which evaluated the prevalence of gastric cancer among adults reporting to specialized medical services has shown that the national prevalence of gastric cancer was 2.9 to illnesses at 100,000 people aged over 18, with high variations by region: $2.8\%_{000}$ inhabitants in Moldova, $6.6\%_{000}$ in Transylvania, $3.45\%_{000}$ in the western region and $1.9\%_{000}$ in Oltenia and Wallachia. Demographic peculiarities of gastric cancer patients were as follows: 66.4% were males compared with 33.6% women, 51.7% were from urban areas compared with 48.3% in rural areas, and the average age of patients was 63.07 ± 12.10 years. 95.5% of cases had at the time of diagnosis, advanced gastric cancer most commonly located in the gastric body

(40.1%) and antrum (33.8%). According to Borrmann classification, 31.4% had type I polypoid, 32.1% type III ulcero-infiltrative. Histological, according to Lauren classification, the most common histological type was intestinal type (63.8%). Early gastric cancer was diagnosed in 4.4% of patients (10).

TEMPORALTRENDS OF GASTRIC CANCER

In 1930, gastric cancer was the leading cause of cancer mortality in Europe and the U.S. In the past 70 years the death rate declined dramatically in developed countries, especially due to the decrease of prevalence 11). However in the last 30 years the incidence of gastric adenocarcinoma at cardial level increased 5-6 times in developed countries.

Tumors in the cardial area are now nearly half of gastric cancers among men in the U.S. and UK. Also increased the incidence of esophageal adenocarcinoma whose main etiologic factors are represented by obesity, gastroesophageal reflux disease and Barrett's esophagus.Cardial adenocarcinomas share certain epidemiological characteristics of oesophageal adenocarcinoma (13).

In England the standardized incidence rate was reduced to more than half, from 30 cases per 100,000 male populations in the years 1975-1977 to 13 cases per 100,000 men in 2006-2008. The downward trend is similar for women too, being estimated at 14 cases per 100,000 women to 5 new cases per 100,000 women (14).

Gastric cancer was the first cause of cancer death in the world until 1980, when it was surpassed by lung cancer.

DISTRIBUTION OF GASTRIC CANCER BY GENDER, ENVIRONMENT, AGE AND RACE

Gastric neoplasm affects both sexes, but unevenly, the male / female ratio being of 2-3/1, with no significant difference between urban and rural areas, the incidence being certainly higher for vulnerable social categories.

Disease frequency increases significantly with age, the elderly being the most affected groups. Gastric cancer is an exception under age 30, after 40 years the frequency of disease increases reaching the maximum level after the age of 60.

In Romania, the average age of patients with gastric cancer is 68 years. Male / female ratio, regardless of histological form remains around 2.41 / 2.5 (15). By frequency indices, in our country gastric cancer ranks second among men neoplasia and third at women. In the world, Romania ranks seventh of gastric cancer in men and eleven among women (15).

Black race seems to be more frequently affected by the disease, recent statistics suggesting a ratio of 60/36 in favor of black population. Immigrants initially keep the risks of disease similar to those in origin countries, but these risks are modified in descendants, becoming similar to those from the area where they migrated, demonstrating the important role of environmental factors in the occurrence and progression of the disease.

Cardial carcinoma affects men 5 times more than women and 2 times the whites more frequently than the black race. More, proximal carcinoma incidence rate is relatively high in certain professional groups (14). An upward trend recorded the esogastric region carcinoma (6.18%) with reserved prognosis, decreasing age of onset,

predominantly diffuse infiltrative type, predominantly in men.

PATHOLOGICAL CONSIDERATIONS ON GASTRIC CANCER

Approximately 90% of gastric cancers are adenocarcinomas, divided into two categories: well differentiated or intestinal type and undifferentiated or diffuse type. Intestinal type correlates with gastric body gastritis, gastric atrophy and intestinal metaplasia, whereas the diffuse type is related to pangastritis without atrophy (16).Intestinal type is more common in men, black race and older age groups, while the diffuse type is about equally distributed by gender and is more common in young people. Intestinal type is predominant in high risk areas such as East Asia, Eastern Europe, South America and Central America (17). Diffuse type has aa more uniform geographical spread. Reducing the incidence of intestinal type is based on the general decline of gastric cancer. In contrast, the incidence of diffuse type, especially the cell "in signet ring" increased.

For Romania, the report of histopathological types is represented by the intestinal carcinoma / diffuse carcinoma of approximately 1.7 / 1.8, i.e. 46-48% of intestinal type carcinoma and 27% diffuse type carcinoma, unclassified forms being of 25-27% (15).

After WHO histological types for Romania are: papillary carcinoma 4.6%, tubular carcinoma 26.1%, mucipar carcinoma 17.2%, carcinoma with "signet ring" cell 22% and undifferentiated carcinoma 29.9% (9).

By mode of histological differentiation, well-differentiated carcinoma accounts for about 23%, average differentiated carcinoma 18.6%, poorly differentiated carcinoma 28% and undifferentiated carcinoma 30%. The most striking upward trend is manifested by poorly differentiated carcinoma. A retrospective study conducted in our country by the Ministry of Health in 2000 showed an increased incidence of poorly differentiated carcinomas in the "signet ring" as other forms with poor histological differentiation which recorded 57.9%.

An upward trend recorded the esogastric region carcinoma (6.18%) with reserved prognosis, decreasing age of onset, predominantly diffuse infiltrative type and predominantly in men.

In patients younger than 40 years, gastric carcinoma is most often diffuse, with high localization and low histological differentiation. The incidence of this form is currently about 1.92% (18).

An improvement in the prognosis of gastric cancer could be obtained by the discovery of neoplastic process in the "early carcinoma" stage due to endoscopic diagnostic techniques with histological confirmation. Thus, of all gastric cancers included in the study of authors from Cluj-Napoca, early carcinoma accounted for 5.1% of the total (11).

Intestinal metaplasia of different types is associated with gastric cancer in percentage of 11.5% and with duodenal ulcer in percentage of 4.8%. Intestinal metaplasia type III, colonic, represents between 8-12% of the total intestinal neoplasia, being found in approximately 3% of all gastric biopsies from patients with various symptoms, which were subjected to endoscopic biopsies.

Regarding the correlations between different types of dysplasia and gastric cancer types, was revealed that non metaplastic-dysplasia is found in 46.2% of diffuse-type gastric cancer, 7.7% of intestinal type cancers and 53.8% of intermediate type cancers.

Dysplasia of mucosa with intestinal metaplasia was found in 23.1% of diffuse-type cancers, 84.6% of intestinal type cancers and 30.6% of intermediate type cancers.

The causes which determine gastric cancer include genetic and environmental factors. Genetically are described the p53genetic mutation, loss of heterozygosity (LOH) at APC locus, deletion or suppression of FHIT gene. Environmental factors include rich diet in salt, nitrates, chronic alcohol consumption, and previous gastric interventions.

Helicobacter pylori was considered by WHO as class I carcinogenic agent, the risk of detecting a malignant tumor of the distal portion of the stomach is 2-3 times higher in patients with Helicobacter pylori infection than in the control group.

CONCLUSIONS

Since 1980 the prevalence and mortality due to gastric cancer (particularly the distal localization) decreased significantly in all countries and in all ages of 2-7% per year and instead increased the number of patients with adenocarcinoma located at the esogastric junction and at the gastric initial portion.

Gastric cancer still remains a disease with extremely poor prognosis and increased mortality which is exceeded only by lung cancer mortality.

In general, the countries with high incidence of gastric cancer have a survival rate higher than the countries with low incidence. This association is based mainly on the difference in survival due to tumor localization in the stomach. Thus, tumors located in the cardial area have a worse prognosis than those in the pyloric antrum with a lower 5-year survival and increased perioperative mortality.

When the tumor is localized to the mucosa, 5-year survival is approximately 95%. In the U.S. few cancers are discovered at an early stage, which leads to decreased 5 years survival at fewer than 20%. Similarly, in European countries the survival varies between 10-20%.

Possibility to perform screening for early detection of cancer resulted in a significant decrease in mortality in high-risk areas. In Japan, where are used screening procedures very frequently, gastric cancer mortality has halved from 1970.

In Romania, gastric carcinoma does not tend to decrease the incidence seen in developed countries. Moreover, there are growing higher forms of aggression.

NEW INSIGHT INTO MOLECULAR EPIDEMIOLOGY OF MRSA STRAINS IN ROMANIA

A recent study by Székely and co. brings new information regarding methicillin-resistant *Staphylococcus aureus* strains (MRSA) circulating in Romania. The authors used pulsed-field gel electrophoresis (PFGE), *spa* typing and SCC*mec* typing to describe the clonal relations and virulence profiles of MRSA isolates from patients admitted to intensive care and surgical units, during 2010, in Mureş County Emergency Clinical Hospital. The study identified 25 pulsotypes clustering into 4 major clonal groups, named from A to D. The majority of MRSA isolates, included into clonal group A (82%), were associated with the successful HA-MRSA clone, spa type t030, which carried SCC*mec* type III and enterotoxin A genes. Group B was represented by 15 % of the strains, which were assigned to spa types t127, t015 and t321. These strains harbored SCC*mec* type IV and enterotoxin genes. Two strains that belonged to spa types t044 and t582 were included into clonal groups C and D, respectively. They were PVL-producing strains (Panton-Valentine leukocidin) and had genes encoding for enterotoxin G and SST-1 (toxic shock syndrome toxin). The remaining two strains were non-typeable by PFGE and belonged to spa type t034, which is characteristic for livestock-associated MRSA (LA-MRSA). These strains were isolated from community onset infections, harbored SCC*mec* type V and were negative for the searched exotoxins. The study concluded that most MRSA strains were clonally related and suggested an intrahospital origin, but also pointed out the danger of new emerging LA-MRSA strains. (Székely E, Man A, Mare A, Vas KE, Molnár S, Bilca D, *et al*. Molecular epidemiology and virulence factors of methicillin-resistant *Staphylococcus aureus* strains in a Romanian university hospital. *Rev Rom Med Lab*. 2012; 20: 370-382).

INVOLVEMENT OF IMIDAZOLINE SYSTEM IN DRUG ADDICTION

Discipline of Pharmacology

INVOLVEMENT OF IMIDAZOLINE SYSTEM IN DRUG ADDICTION (Abstract): The imidazoline system (a concept which is barely over decades old) consists in imidazoline receptors I_1, I_2 and I_3 and their active endogenous ligands, the most important of which is agmatine. Brain contains both I_1 and I_2 of imidazoline receptors. One of the most important functions of this system is modulation of different behaviour components, such as suicidal behaviour, stress, anxiety, food intake etc. Own data preliminary data revealed different effects of α_2 and imidazoline-receptors antagonists on morphine conditioned place preference (efaroxan reduces its intensity, while idazoxan has no influence); this reveals a possible different role of I_1 and I_2 receptors in reward system. **Keywords**: IMIDAZOLINE RECEPTORS, REWARD SYSTEM, DRUG ADDICTION

The concept of imidazoline brain system is only a few decades old. The imidazoline system consists in imidazoline receptors I_1, I_2 and I_3 and their active endogenous ligands. I_1 and I_2 imidazoline receptors are membrane located non-adrenergic sites. Brain contains both I_1 and I_2 imidazoline receptors.

One of the most important natural agonists is agmatine (decarboxylation product of arginine). Identification of agmatine as an endogenous ligand for imidazoline receptor leads to important knowledge over imidazolinic system roles in the body (1). There is a particularly of the connections between imidazoline and adrenergic brain system, as certain imidazoline agonists and antagonists also act on α_1 and $\alpha_2$adrenergic receptors.

Existing evidence show the importance of imidazoline in modulating central nervous system functions. Existent data show that I_1 and I_2 receptors have different effects on some behavior components, such as suicidal behavior, stress, anxiety, food intake etc.

Imidazoline system is important for both normal and pathological behavior. Thus, changes in the imidazoline system balance have been detected certain neurological and especially psychiatric diseases.

REWARD SYSTEM

The biological mechanism and neural pathways mediating behavior motivated by events commonly associated with pleasure have been identified and described. These events are termed "rewards" and are viewed as primary factors governing normal behavior. The neural pathways involved in pleasure-mediated behavior are referred to as "brain reward system". Main

rewards may be classified as natural (such as food, liquid intake, sex) and environmental (drugs of abuse, brain electrical stimulation of certain areas). The neuroanatomical elements of rewarding stimulation have been identified and ventral tegmental area, nucleus accumbens, ascending mesolimbic dopamine system, middle forebrain bundle are among the most important structures mediating reward. Dopamine is considered the most important neurotransmitter responsible for reward, but glutamate, serotonin, substance P, norepinephrine, endogenous opioids, GABA are also critically involved (2).

SUBSTANCES ACTING ON IMIDAZOLINE RECEPTORS AND THEIR INFLUENCE ON REWARD- RELATED BEHAVIOR

The imidazoline system has at least two important characteristics: some agonist and antagonists also act on the α-adrenergic system, and agmatine is synthesized from arginine, which is also a source of nitric oxide. There are I_2 binding sites on monoamine oxidase (MAO) molecule, an essential enzyme for catecholamine metabolism. The fact that some agonists or antagonists of imidazoline receptors have also effect on α-adrenergic receptors or MAO also suggests certain interactions between imidazoline and adrenergic systems.

Imidazoline receptors have been identified in all brain areas; as to imidazoline system involvement in addictions, it is of special importance that this type of receptors is present in brain reward system cells (neurons and neuroglia). Experimental research on laboratory animals shows that agmatine influences some types of drugs addiction, most of them referring to opioid addiction. Clonidine (mainly known as α_2-receptors agonist, but also I_1-receptors agonist) is a very important agent used for withdrawal treatment.

Agmatine itself has no reinforcing effect, but it determines a reduction in opioid dependence either systemically (intraperitoneally or subcutaneously) or centrally (intrathecally or intracerebroventricularly) (3). This effect is believed to be mediated by imidazoline I_1-receptors (4).

Pretreatment with agmatine (40 or 80 mg/kg, intraperitoneally) significantly inhibited the acquisition of intravenous morphine self-administration as assessed by the nose-poke response and morphine intake. The mean number of days required to meet the acquisition criteria for intravenous morphine self-administration was significantly prolonged. After acquisition of intravenous morphine self-administration, chronic administration of agmatine (40 or 80 mg/kg x 30 days, bid, intraperitoneally) during the extinction period significantly prevents the re-acquisition of intravenous morphine self-administration. The ability of agmatine to inhibit the acquisition and re-acquisition of intravenous morphine self-administration suggests a possible use of agmatine in the treatment of opioid dependence (5).

Agmatine prevents tolerance to opioids analgesia either systemically (intra-peritoneally or subcutaneously) or centrally (intrathecally or intracerebro-ventricularly) (6) and reduces fentanyl self-administration (7). These facts can be of real therapeutic benefit, especially as numerous recent studies proved that I2-agonists, including agmatine, potentiate opioid- induced analgesia (8, 9, 10) Also, a very beneficial fact is reversion of morphine-induced memory impairment by agmatine, effect which is antagonized by idazoxan (I2 antagonist) (11).

Also, agmatine reduces the intensity of

morphine-induced conditioned place preference in mice (12) in a dose-dependent manner. Conditioned place preference is an experimental model investigating the rewarding effects of different stimuli, where the animal develops an association between the subjective states produced by the stimuli and the environmental factors associated to these stimuli.

There are also other addictive substances than opioids the behavioral effects of which are lowered by agmatine.

Repeated agmatine treatment altered nicotine sensitization in mice (13).

Regarding the effects of psychostimulants on brain reward, several studies have also lead to relevant conclusions. Also, agmatine, at doses that did not produce place preference, aversion or altered motor activity significantly decreased the development of methamphetamine-induced place preference when agmatine was administered in combination with methamphetamine during place conditioning (14).

The specific I_1 receptor agonist moxonidine reduces cue-induced reinstatement of cocaine-seeking behavior, suggesting that moxonidine might have substantial potential for treating addictive disorders (15).

Agmatine (5-20 mg/kg) significantly blocked ethanol (0.5 g/kg)-induced locomotor hyperactivity. These doses of agmatine did not affect the locomotor activity in naive mice when they were administered alone. Other results suggest that agmatine has an important role in ethanol-induced locomotor hyperactivity in mice. There may be a relationship between the addictive psychostimulant effects of ethanol and central agmatinergic system (16).

A theoretical rationale supports the fact that tizanidine (α_2-adrenoreceptor agonist that inhibits noradrenaline release and binds to imidazoline receptors) can be an effective treatment for alcohol withdrawal syndrome as well as for the prevention of relapses (17).

Our preliminary data revealed different effects of α_2 and imidazoline-receptors antagonists on morphine conditioned place preference (efaroxan, 1mg/kg reduces its intensity, while idazoxan, 0.25mg/kg has no influence), while neither of these substances significantly modifies the intensity of opioid dependence in rats.

DISCUSSION

Based on the presented data referring to substances acting on imidazoline receptors and the way they modulate the reinforcing effects of some addictive substances, several hypotheses referring to the mechanisms by which imidazoline system modulates reward pathways have been formulated.

There are important functional connections between imidazoline system and other neuromediator systems involved in drug dependence. The most important functional connections in case of imidazolinic system are those with catecholaminergic system.

A first very important element of these connections is that some I_1-receptor agonists (such as clonidine) are also α_2-receptors agonists. Other substances which act as competitive I_1-receptor antagonists (such as efaroxan) also act on adrenergic receptors.

The problem of imidazoline system involvement in addiction might also be connected with nitric oxide involvement in the mechanism of production of those dependences. Arginine (the amino acid which also serves for arginine precursor) is also the main source of nitric oxide. Among others, a possible involvement of inducible nitric oxide system has also been incriminated for

agmatine effect of reducing morphine-induced conditioned place preference, as minoguanidine, a specific inducible NOS (nitric oxide synthase) inhibitor, significantly reduced the effect of agmatine (18). On the other hand, agmatine is a weak competitive inhibitor of neuronal NOS (9). It is known that morphine administration is followed by increased NO released, due to increased activity of constitutive NOS, but it decreases the activity of inducible NOS (via constitutive NOS-derived NO) (20, 21).

Agmatine, administered before morphine withdrawal determined a decrease of glutamate level in nucleus accumbens (a key element in reward mesolimbic dopaminergic pathways) in rats; also, agmatine acts as a NMDA-receptor antagonist (22, 23). Given the essential role of glutamate neurotransmission in brain reward system, these might serve as a reasonable explanation for the above-presented data related to agmatine capacity of reducing some aspects related to drug intake.

However, many aspects related to imidazoline-reward system interaction mechanisms are yet to be studied.

CONCLUSIONS

Imidazoline agonists determine inhibitory effects on several aspects related to the action of some drugs of abuse on reward-modulation pathways. Considering their potentiating effect on opioid analgesia and reversal of morphine-induced memory impairment, imidazoline agonists might represent valuable pharmacological agents for addiction treatment. Also, substances such as clonidine, which has been long used in withdrawal treatment, might due their beneficial effects in patients with opioid or alcohol withdrawal not only to imidazoline receptors blockade but also to adrenergic receptors blockade. Existent data are also opening the perspective of therapeutic use of other imidazoline system modulators.

Regunathan, 2006 (24) showed that agmatinase inhibitors (substances which blocks the enzyme which brakes-down agmatine) will offer a way to enhance agmatine brain concentration. This may be a useful in therapy to reduce the intensity of opioid addiction or even opioid withdrawal syndrome.

We believe that both imidazoline I_1 and I_2 agonists and antagonists might modulate reward system activity, this being of particular relevance for therapy.

Involvement of imidazoline system in behavior is surely a very fruitful study domain.

THERAPY WITH CLIMARA IN SURGICAL MENOPAUSE (Abstract): Hormone replacement therapy in surgical menopause is a prophylactic measure that is used for preventing the short and long term effects of the lack of ovarian hormones. **Material and methods:** This is a retrospective study conducted between 2004 and 2006 at the Iasi "Elena-Doamna" Hospital of Obstetrics and Gynecology on two series of patients: 46 patients with surgical menopause who received treatment with transdermal estradiol (Climara), and 20 surgical menopause patients not receiving this treatment who served as controls. **Results:** A decreases in the average levels of total cholesterol, triglycerides and LDL cholesterol and an increase in the HDL cholesterol level were identified in the series receiving Climara compared to the controls. The climacteric symptoms improved in the patients receiving treatment. **Conclusions:** Transdermal therapy with estradiol (Climara) is an effective method of treatment in surgically induced menopause**. Key words:** SURGICAL MENOPAUSE, CLIMARA, CARDIOVASCULAR DISEASE

Surgically induced menopause by bilateral oophorectomy is followed by short and long term effects: cardiovascular disease and osteoporosis. Cardiovascular diseases are one of the main causes of illness and death for women in industrialized countries (1,2).

Epidemiological studies (3) show that the incidence of cardiovascular diseases increases in postmenopausal women The risk for ischemic heart diseases is higher in women with ovariectomy, and hormone replacement therapy reduces this risk (4, 5). Studies show that a decrease in ovary function from bilateral ovariectomy increases the risk of myocardial infarction and the use of estrogens reduces this risk (6,7,8). The positive effect of estrogenic therapy with estradiol on cardiovascular diseases was proved ever since many years.

The favorable effect of estrogenic therapy in women with surgical menopause is due to the action on plasma lipoproteins and endothelial function (9, 10, 11).

MATERIAL AND METHODS

Our study is a retrospective study carried out at the Iasi "Elena-Doamna" Hospital of Obstetrics and Gynecology during 2004-2006. 46 patients with bilateral oophorectomy received transdermal therapy with 3.9 mg estradiol (Climara) (series I) and 20 patients with surgical menopause

not receiving this treatment served as control group (series II).

The following data were recorded: age, socio-economic status, personal history, type of intervention, symptoms, and biological blood levels during the research. A standard file was used to record all changes noticed during therapy.

The collected data were transferred to EXCEL and SPSS 17.0 databases and processed with the predefined statistical functions. For the statistical analysis (ANOVA) both descriptive and analytical methods were used. The statistical indicators used were:

- Mean value: simple arithmetic mean, median, module;
- Dispersion: standard deviation, variance.

Data were presented with 95% confidence intervals, and for testing the differences the χ^2 and t-Student's t- tests were used.

The correlation between parameters was analyzed by using the Pearson's correlation coefficient (r), which ranges between $-1 < r < +1$, indirect correlation if the values are negative, and direct correlation if the values are positive, and its square form (R^2).

RESULTS

*Age-distribution***.** After comparatively analyzing patients' age in the two study series and applying the ANOVA test, the following were noticed:

- In the series of women with surgical menopause treated with Climara (series I), the age varied between 35 and 60 years, with a moderate variance in the range of values (11.41%); the mean age of this series was 49.22;
- In the series of women with surgical menopause without treatment (series II), the age ranged between 40 and 60, with a slightly reduced variance in the range of values compared to series I (10.50%); the mean age of this series was 50.40.

Rural-urban distribution was homogenous for both study series – the patients came mainly from urban areas: series I – 89.1%, series II – 70% (χ^2=2.42; GL=1; p=0.119).

Distribution of patients according to marital status showed a higher percentage of married women: series I (95.7%) and series II (100%), no other significant differences between the two series being recorded (χ^2=0.03; GL=1; p=0.868).

Distribution of patient according to educational level showed statistically significant differences between the two series (χ^2=3.95; GL=1; p=0.047), in series I the percentage of women with high school education being significantly higher (89.1% *vs.* 65%).

Case history

The distribution of patients according to body mass index showed that there were more overweight women in the series receiving Climara (45.7% *vs* 35%), and no obese women in series II (19.5% *vs* 0%), this distribution being statistically significant (χ^2=7,18; GL=2; p=0.028).

The average BMI values showed significant differences (t=4.15; GL=64; p<0.001) and according to that series I was classified as being made of overweight women while series II was generally made of normal weight women.

The average blood pressure was normal for both series I (13.1/7.98 mmHg) and series II (13/8 mmHg).

Case history data revealed:

- Series I: hemorrhagic uterine fibro-

ma (71.7%); obesity (15.2%); dysfunctional hemorrhage (10.9%);

- Series II: hemorrhagic uterine fibroma (50%); varices (45.0%); uterine fibroma (25%); AHT (25%); chronic cervicitis (20%).

Most women were menopausal for 1-4 years, 50% in both study series, followed by those menopausal for less than 1 year (32.6% in series I and 45% in series II), distribution of frequency which is not statistically significant (χ^2=2.16; GL=2; p=0.340).

Symptoms

Hot Flushes: -in series I, when the study was initiated 73.9% of the patients were experiencing hot flushes, its frequency decreasing to 41.3% after 12 months, with alternating periods of hot flushes, and at the end of the study this symptom was present in only 8,7% of the cases (χ^2=40.53; GL=3; p<0.001);

- at the beginning of the study hot flushes were experienced by 80% of the women in series II, its incidence significantly decreasing with every subsequent medical check up, being present in about 30% of the women when last monitored (χ^2=10.56; GL=3; p=0.014).

Migraine:-in series I, at the beginning of the study, 28.3% of the patient complained of migraine, the same percentage being recorded after 6 months of therapy but with migraine-free intervals in 19,6% of the women; at the end of the study this symptom was reported by 4,3% of the patients (χ^2=11.33; GL=3; p=0.010);

- in series II, at the beginning of the study in 50% of the women had migraines their incidence decreasing after 2 years below 10% (χ^2=13.37; GL=3; p=0.004).

Instability /agitation: - in series I, instability/agitation was rarely found at the initial examination investigation, after one year it being still present in only one patient (χ^2=2.23; GL=3; p=0.525);

- in series II, at the beginning of the study, instability/agitation was found in 10% of the women; after 6 months 50% of the patients in this series presented this symptom in 40% of them alternating with symptom-free interval; at the end of the study instability/agitation was found in 25% of the patients in this series (χ^2=7.99; GL=3; p=0.046).

Insomnia: -in series I insomnia significantly decreased in frequency during the study interval, and varied in intensity from 43.5% to 6.5% (χ^2=19.20; GL=3; p=0.0002);

- in series II, insomnia was present in about 30% of the cases throughout the study (χ^2=0.17; GL=3; p=0.982).

Libido: - in series I, after 6 months monitoring, 35 % of the patients had normal libido, and at the end of the study 37% of the patients (χ^2=20.05; GL=3; p=0.0002);

- in series II, libido was a very rare symptom (χ^2=1.04; GL=3; p=0.792).

Pollakiuria: -series I: pollakiuria was met in 8.7% of the cases at the beginning of the study, but its frequency diminished until it disappeared at the end of the study (χ^2=4.16; GL=3; p=0.245);

- series II: pollakiuria was present every now and then in about 20% of the cases throughout the study (χ^2=0.28; GL=3; p=0.965).

Exercise urinary incontinence: -this symptom was met in 4.3% of series I patients at the beginning of the study and its frequency diminished until it disappeared at the end of the study (χ^2=2.26; GL=3; p=0.520);

- in series II, IUE was a symptom reported intermittently by 1-2 patients

(χ^2=0.64; GL=3; p=0.887).

Biochemical parameters

Blood glucose level: The average blood glucose levels were initially significantly higher in series I (p<0.05). During their monitoring, a significant decrease was recorded in series I, while in series II patents the levels kept increasing so that at the end of the study significantly higher blood glucose levels were recorded in series II (p<0.05).

Triglycerides: During the monitoring, the beneficial effect of the treatment with Climara was evident, the average triglyceride levels being significantly lower when compared with those in series II patients (p<0.001) in which triglyceride level significantly exceeding the reference range (figure 1).

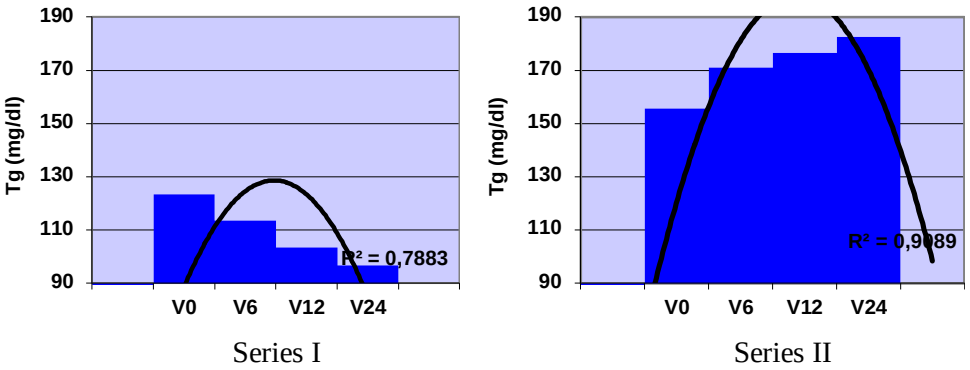

Fig. 1. The evolution of average triglycerides levels in the study series

Total cholesterol: All along the monitoring, the average total cholesterol levels in series I women decreased significantly below the reference range, while in series II they kept increasing slightly exceeding the upper reference range. The average total cholesterol levels showed significant differences between the two series (p<0.05), emphasizing the beneficial effect of the treatment with Climara (figure 2).

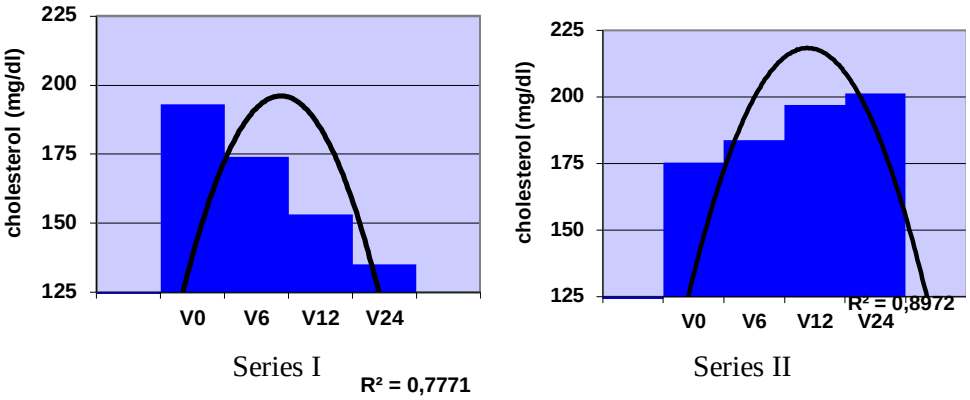

Fig. 2. The evolution of average total cholesterol levels in the study series

LDL cholesterol: The average LDL cholesterol levels were significantly higher at the beginning of the study in series I when compared with those recorded in series II ($p<0.05$), but during the monitoring we noticed the beneficial effect of the treatment with Climara expressed in significant decreases in LDL-cholesterol levels, while in the series without treatment its average levels increased in time ($p<0.001$) (figure 3).

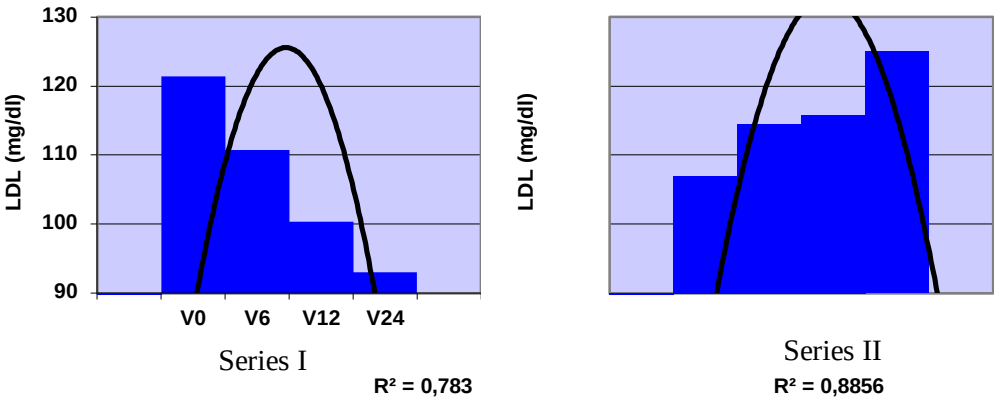

Fig. 3. The evolution of the average LDL cholesterol levels in the study series

HDL cholesterol: The average HDL cholesterol levels have increased in both study series, but in the patients treated with Climara, all along the monitoring the average values were significantly higher ($p<0.001$).

DISCUSSION

One of the most important roles of hormone replacement therapy is that it eliminates the symptoms of menopause, especially of the vasomotor and urogenital symptoms that appear immediately after oophorectomy (12).

The long term benefit is that it lowers the risk of developing cardiovascular diseases. The protective cardiovascular effect of estrogen therapy manifests through favorable effects on lipid metabolism (13).

In our study comparing the menopause symptoms in the two patient series the following are evident:

- at baseline:
  - no significant differences in the the investigated symptoms ($p>0,05$);
- at 24 months:
  - series I: libido was significantly more frequent ($p=0,017$) and hot flushess disappeared ($p<0.001$).
  - series II: significantly more hot fluses ($p=0,065$), associated with irritability/aggitation ($p=0,012$), insomnia ($p=0,030$) and polakiuria ($p=0,041$).

As to biochemical parameters at 24 months: - triglycerides, total cholesterol and LDL cholesterol levels decreased significantly ($p<0.001$) in the patients on Climara treatment ;

- HDL cholesterol levels have increased in both study series. In series I patients the levels were significantly higher ($p<0.001$), demonstrating the cardiovascular protective effect of Climara treatment.

No patient discontinued therapy at two years.

CONCLUSIONS

The clinical benefits of hormone replacement therapy in the elimination of

menopause symptoms are widely accepted, as proved by our study in which the patients receiving Climara became menopause-symptom free.

Long term prevention of cardiovascular diseases is an important benefit. In series I patients significant decreased in triglycerides, total cholesterol and LDL cholesterol levels, and increases in HDL cholesterol levels, with protective cardiovascular role, were found.

The treatment must be initiated as soon as possible.

Climara administrated in surgical menopause women resulted in a short and long term improvement in their quality of life. Climara is well tolerated by women in surgical menopause.

ARRAY CGH: TECHNICAL CONSIDERATIONS AND APPLICATIONS (Abstract): During the past ten years a particular molecular technology - array comparative genomic hybridization (aCGH) - has received a great deal of attention. Array CGH can detect simultaneously sub-microscopic copy number changes across the whole genome, thus overcoming the limitations of karyotyping or locus-specific techniques. Array CGH has become an important tool for clinical diagnostics and gene-identification studies and is having a great impact on the understanding of pathologies, the counselling of families and patient management. Different types of array CGH platforms at increasingly higher resolution have been developed, differing mainly in the type of the interrogating probes and in their coverage of the genome. Here, we review the array CGH methodology and its various applications in clinical diagnostics and research. Although it's an expensive technology and differentiating between pathogenic and benign copy number variations is a challenging task, array CGH is an efficient and robust method for assesing disease-causing genomic imbalances and will probably replace karyotype as the primary cytogenetic test. **Key words:** ARRAY COMPARATIVE GENOMIC HYBRIDIZATION, MOLECULAR KARYOTYPING, COPY NUMBER VARIATION, MENTAL RETARDATION

Explorările citogenetice reprezintă o metodă importantă de diagnostic în clinică, anomaliile cromozomiale determinând: sindroame plurimalformative, retard mental, tulburări de comportament, tulburări de sexualizare şi reproducere, cancere. Începând cu anii '70, tehnica de marcaj cromozomial în benzi G, efectuată pe celule aflate în diviziune şi folosind o mărire de 10.000 ori, a fost principalul instrument folosit în diagnosticul anomaliilor cromozomiale echilibrate şi neechilibrate. Cariotipul evaluează întregului genom, evidenţiind pierderile sau câştigul de material genetic într-un singur test, dar nu poate detecta anomalii mai mici de 5-10 Mb şi nu poate fi decât parţial automatizat (1).

Prin introducerea tehnicii FISH (*Fluorescent In Situ Hybridization* – Hibridizare fluorescentă in situ) a devenit posibilă detecţia anomaliilor cromozomiale submicroscopice. FISH poate detecta un locus (evidenţiind microdeleţiile specifice anumitor sindroame plurimalformative) sau mai mulţi loci (evidenţiind regiunile subtelomerice) într-un singur test, dar este o metodă laborioasă, care necesită o evaluare clinică minuţioasă, importantă pentru alegerea

adecvată a sondei(lor) (1).

Tehnologiile bazate pe microrețele a schimbat major analiza genomului uman, combinând rezoluția înaltă a tehnicii FISH cu posibilitatea de a scana întregul genom oferită de cariotip. Hibridizarea genomică comparativă pe microrețele (aCGH) permite detecția precisă şi specifică a anomaliilor cromozomiale neechilibrate din întreg genomul, la o rezoluție mai mică de 10 kb (1).

METODOLOGIE

Principiul aCGH este asemănător cu cel al CGH convențional. Microrețelele sunt alcătuite din câteva mii de sonde diferite (fiecare specifică unei secvențe de ADN), nemarcate, fixate pe o lamă de sticlă sau pe un *chip* de silicon, în mici puncte („spots") cu coordonate precise, dispuse în rânduri ordonate, sub forma unei rețele cu densitate înaltă (*chip* ADN). Pentru realizarea analizei este extras ADN genomic atât de la pacient (din limfocite, fibroblaste sau alte țesuturi) cât şi dintr-o probă de referință (aceeaşi linie celulară ca a pacientului dar provenită de la unul sau mai mulți indivizi normali). Cele două probe de ADN sunt fragmentate (cu ultrasunete sau prin digestie cu o enzimă de restricție), marcate cu fluorocromi diferiți (Cy3 - verde pentru proba test, Cy5 - roşu pentru proba martor), amestecate în cantități egale, denaturate şi co-hibridizate pe microrețea (2,3). Secvențele de ADN repetitiv sunt blocate prin adăugarea de Cot-1 ADN. După spălare, microrețelele sunt scanate cu un *microarray scanner*, iar imaginile obținute sunt analizate folosind un program ce cuantifică intensitățile de emisie ale fluorocromilor roşu şi verde pentru fiecare spot din rețea şi calculează raportul lor. Acest raport este proporțional cu raportul numărului de copii ADN din genomul martor şi cel de referință. Dacă intensitățile celor doi fluorocromi sunt egale într-un spot, (raport Cy3/Cy5=1, sau $\log_2$=0) această regiune din ADN-ul pacientului este interpretată ca fiind normală/echilibrată. Dacă este prezentă o deleție, ADN-ul martor hibridizează preferențial, iar raportul Cy3/Cy5 va fi subunitar (ex. 1:2, $\log_2$=-1). În schimb, dacă există o duplicație, ADN-ul pacientului va hibridiza preferențial, iar raportul Cy3/Cy5 va fi supraunitar (ex. 3:2, $\log_2$=0,58.) (fig. 1) (2).

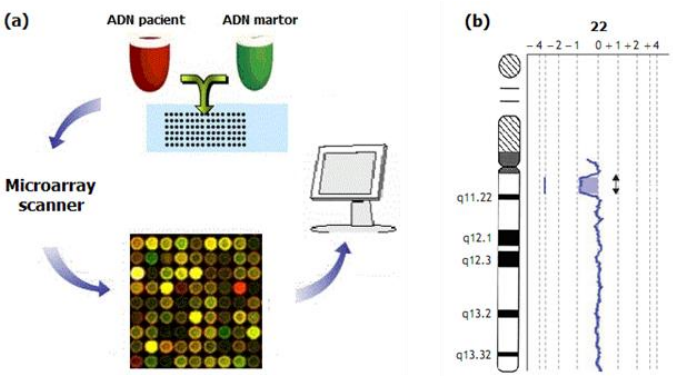

Fig. 1. Principiul tehnicii aCGH.

(a) Proba ADN de la pacient şi cea de referință sunt marcate cu fluorocromi diferiți şi cohibridizate pe o microrețea ce conține fragmente de ADN genomic fixate pe o lamă de sticlă. După scanare, semnalele fluorescente sunt captate şi analizate digital, în funcție de intensitate, rezultând o reprezentare grafică.
(b) Exemplu de aCGH: deleție 22q11.21. Axa orizontală indică logaritmul raportului de fluorescență (valori negative – deleții; valori pozitive - duplicații). Axa verticală indică locusul pe cromozom.

TIPURI DE REȚELE

În practică pot fi folosite diferite tipuri de rețele: rețele „țintite", rețele ce acoperă întregul genom, sau o combinație a lor.

- ***Rețelele „țintite"*** (*targeted*) conțin fragmente specifice de genom - precum cele din regiunile subtelomerice sau cele în care se produc frecvent microdelеții/ microduplicații implicate în producerea unor sindroame plurimalformative -, dar nu acoperă întregul genom. Acest tip de rețea este folosit în scop diagnostic (postnatal sau prenatal) sau de screening (4,5).
- ***Rețelele pan-genomice*** („*whole genome*" sau „*tiling path*" - cu clone suprapuse) permit acoperirea întregului genom cu o rezoluție care depinde de distanța dintre sonde; acest tip de rețele identifică cu 5% mai multe anomalii decât o rețea „țintită" (6). Rețelele „*whole genome*" cu densități foarte mari sunt folosite în cercetare şi au dus la definirea a noi sindroame şi la caracterizarea punctelor de ruptură în diverse anomalii cromozomiale sau mutații genice, dar nu au aplicabilitate clinică datorită identificării a numeroase CNV (*Copy Number Variations* - variații ale numărului de copii), dificil de interpretat (7).

TIPURI DE SONDE

Sondele pot fi de tip BAC (*Bacterial Artificial Chromosome* - cromozomi artificiali bacterieni), ADN complementar, oligonucleotide sau SNP (*Single Nucleotide Polymorphism* – polimorfism al unui singur nucleotid). Inițial au fost folosite sonde de tip BAC ce conțin ADN izolat din clone de dimensiuni mari (150–200 kb) dar treptat s-a renunțat la ele deoarece fabricarea lor este laborioasă, iar rezoluția este limitată. Sondele oligonucleotidice, obținute prin sinteză chimică, asigură o rezoluție mare datorită dimensiunilor reduse. Sondele oligonucleotidice care conțin SNP-uri permit atât identificarea dezechilibrelor genomice de tip deleție/duplicație, cât şi a anomaliilor fără modificarea numărului de copii, cum sunt pierderea heterozigozității şi disomia uniparentală (8).

INTERPRETARE

Aplicarea tehnicii aCGH la indivizi normali a identificat numeroase rearanjări genomice, imposibil de detectat prin alte metode. Aceste segmente de ADN, cu lungimi de peste 1 kb, care sunt prezente în genomul persoanelor diferite într-un număr variabil de copii şi nu provin din inserția sau deleția unor elemente transpozabile, au fost numite variații ale numărului de copii (CNV) (9). Termenul este neutru în ceea ce priveşte patogenitatea şi frecvența de apariție, dar în situațiile în care frecvența în populație este de peste 1%, se foloseşte termenul de polimorfism al numărului de copii (10). Relevanța clinică a CNV este incertă, deoarece identificarea unei astfel de variații nu se asociază obligatoriu cu apariția unei boli.

Testarea clinică prin aCGH, indiferent de tipul de sonde sau de rețea utilizată impune următorul algoritm. Dacă este detectată o anomalie patogenică cunoscută, ea va fi validată prin altă metodă (FISH sau Q-PCR) şi raportată. În continuare, vor fi testați părinții cu scopul de a identifica genitorul de la care a fost moştenit CNV. Metoda va fi aplicată şi la viitoarele sarcini pentru a stabili prezența/absența modificării patologice la produsul de concepție. Dacă este detectat un CNV neasociat cu o anumită afecțiune, rezultatul obținut este comparat cu informațiile din *Database of Genomic Variants* (DGV – Baza de date a variantelor genomice), cu scopul de a vedea dacă variația a mai fost întâlnită la indivizi sănătoşi. Dacă anomalia nu este găsită în DGV sau numărul de cazuri rapor-

tate este mic vor fi testați și părinții. Dacă unul din aceştia prezintă CNV-ul, cel mai probabil el reprezintă o variantă benignă. Dacă variația a apărut *de novo*, este aprofundată cercetarea regiunii în care a fost identificat CNV-ul pentru a identifica genele prezente şi posibila lor implicare patologică. În ambele situații CNV este raportat la DGV, astfel încât să poată fi comparat cu rezultatele altor cercetători (7).

Cu timpul, completarea bazelor de date internaționale (DGV, Decipher, Ecaruca), ca urmare a eforturilor colective, va permite detectarea CNV similare şi determinarea patogenității acestora. Deocamdată, în absența eşantioanelor de ADN de la părinți, utilizarea în scop diagnostic a metodei aCGH la rezoluție foarte mare nu este posibilă, datorită sutelor de polimorfisme dificil de interpretat (8).

AVANTAJELE ŞI DEZAVANTAJELE aCGH

Metoda aCGH prezintă numeroase avantaje:

- permite detecția globală, cu rezoluție înaltă a deleţiilor/duplicațiilor genomice, ceea ce constituie un avantaj raportat la metodele țintite (FISH sau MLPA) care oferă informații referitoare la locii a căror secvență de ADN se regăseşte în sondele folosite.
- în raport cu analiza cromozomială clasică, aCGH are avantajul că nu necesită celule în diviziune (deci timpul de obținere al rezultatelor este mai scurt) şi pot fi utilizate şi probe biologice ce nu conțin celule vii (celule recoltate prin biopsie, autopsie sau provenite de la produşi de avort). În plus, prin aplicarea aCGH pe sânge periferic se pot detecta mozaicuri cromozomiale care nu pot fi identificate prin cariotip, deoarece metoda analizează toate celulele nucleate din sânge, în timp ce cariotipul standard e realizat doar pe limfocitele T cultivate *in vitro*, după stimulare cu fitohemaglutinină.
- cantitatea de produs biologic necesară metodei este foarte mică, majoritatea platformelor de aCGH permițând efectuarea analizei şi în condițiile unor probe ce conțin doar câteva micrograme de ADN genomic.
- oferă rezultate definitive într-un timp scurt şi se pretează la automatizare (11).

Dezavantajele aCGH includ:

- imposibilitatea detectării anomaliilor cromozomiale echilibrate (inversii, translocații) şi a poliploidiilor (12, 13).
- costurile per analiză sunt mult mai mari decât cele pentru un cariotip clasic, în special pentru platformele care acoperă întregul genom la o rezoluție foarte mare.
- în cazul identificării unor CNV, este necesară validarea prezenței rearanjărilor genomice prin tehnica FISH sau qPCR, tehnici care permit detecția țintită a secvențelor specifice de ADN (9). Alte tehnici moleculare bazate pe PCR (precum MLPA, MAPH) create pentru evaluarea concomitentă a mai multor loci de interes pot fi de asemenea utilizate, dar au o sensibilitate şi specificitate reduse (10).

APLICAȚIILE METODEI aCGH

Retardul mental şi/sau anomaliile congenitale multiple. O aplicație importantă a tehnologiei aCGH este identificarea anomaliilor cromozomiale la pacienții cu retard mental (RM) idiopatic, asociat sau nu cu dismorfie facială sau anomalii congenitale multiple (ACM). Anomaliile cromozomiale reprezintă cea mai frecventă cauză de RM, iar rearanjările subtelomerice sunt responsabile pentru 5-7% din cazuri (14). Evidențierea anomaliilor cromozomiale neechilibrate subtelomerice prin marcaj cromozomial în benzi G este dificilă, deoa-

rece acest tip de marcaj nu vizualizează capetele cromozomiale. Pe de altă parte, folosirea tehnicii FISH impune obținerea unor preparate metafazice de calitate superioară, iar evaluarea tuturor regiunilor subtelomerice de interes este foarte scumpă şi nu se poate face printr-o singură analiză. În schimb, folosind aCGH se pot identifica un număr mare de rearanjări (deoarece sondele de aCGH acoperă un segment subtelomeric mai mare decât cel corespunzător sondelor FISH), este posibilă evaluarea dimensiunii segmentului cromozomial şi pot fi diagnosticate şi rearanjări complexe, precum asocierea dintre deleția unui segment şi duplicația unui segment învecinat (15).

Folosirea metodei aCGH în cazurile de RM (cu sau fără ACM), a permis identificarea unor duplicații şi deleții noi, precum şi stabilirea prevalenței mozaicurilor cromozomiale. Aplicarea aCGH de înaltă rezoluție ca metodă de testare genetică inițială la pacienți cu RM neselectați a permis detecția anomaliei patogenice în 19% din cazuri, valoare mai mare decât cea obținută prin analiză cromozomială (~3,7%) sau tehnica FISH (~9,5%) (12,16,17). În plus, aCGH a detectat mozaicuri la 8-10% din indivizii cu RM şi dismorfie facială din loturi neselectate (11). Deşi tehnica aCGH stabileşte prezența dezechilibrului genomic (surplus sau absență de material genetic) ea nu indică mecanismul prin care a apărut dezechilibrul, aspect important însă pentru acordarea sfatului genetic, de aceea este recomandată efectuarea cariotipului concomitent cu aCGH pentru toate cazurile cu RM (12).

Analiza celulelor fetale. Aplicarea metodei aCGH în diagnosticul prenatal elimină o serie din inconvenientele analizei cromozomiale fetale (timpul lung – 2-3 săptămâni – de obținere a rezultatului definitiv, posibilele eşecuri de cultură, calitatea slabă a preparatelor cromozomiale şi, corelat cu aceasta, obținerea unui număr redus de benzi cromozomiale). Metoda foloseşte ADN genomic din celule fetale (obținute prin amniocenteză sau biopsie de vilozități corionice) şi poate fi aplicată atât direct (imediat după recoltare) cât şi pe celule cultivate. Sensibilitatea metodei este mai mare decât cea a cariotipului, permițând evidențierea anomaliilor cromozomiale neechilibrate (cu excepția poliploidiilor), inclusiv a rearanjărilor subtelomerice (18). Din rațiuni practice (interpretarea unui CNV, descoperit prin aplicarea unei rețele pan-genomice, este deosebit de dificilă) pentru diagnosticul prenatal se folosesc doar rețele „țintite" care conțin clone genomice pentru regiunile subtelomerice şi cele implicate frecvent în sindroamele cu microdeleții/microduplicații (19).

Având în vedere că majoritatea duplicațiilor şi delețiilor asociate cu boli genomice apar *de novo* şi se pare că au aceeaşi frecvență indiferent de vârsta maternă (spre deosebire de aneuploidii, care se asociază cu vârsta maternă avansată), aCGH ar putea înlocui explorările citogenetice în majoritatea cazurilor de diagnostic prenatal (20). Deoarece această tehnică nu poate detecta translocațiile echilibrate şi poliploidiile, s-a sugerat că în cazul ecografiilor fetale anormale cu aCGH normal ar trebui efectuate ulterior tehnici citogenetice (21).

Metoda aCGH are aplicabilitate şi pentru studiul produşilor de avort (care deseori prezintă anomalii genetice), atunci când nu se poate face cariotip din celulele avortonului sau acesta are o anomalie cromozomială criptică (22).

C**ancerul.** Anomaliile de dozaj genic şi rearanjările cromozomiale apar frecvent în celulele canceroase. Identificarea prin aCGH a unor segmente cromozomiale am-

plificate, deleții ale genelor supresoare a creşterii tumorale şi deleții sau rearanjări cromozomiale ce implică protooncogene oferă noi informații privind genele implicate în cancer. Datorită rezoluției şi sensibilității mari a aCGH, aplicarea acesteia în evaluarea dezechilibrelor genomice din cancer asigură îmbunătățirea diagnosticului, schemelor de clasificare a tumorilor, descifrării şi monitorizării mecanismului de apariție şi de progresie a neoplaziei (23, 24). Totuşi, în condițiile în care în numeroase forme de cancer apar translocații cromozomiale complexe, aplicarea acestei tehnologii în scop prognostic este limitată, datorită incapacității de a detecta translocațiile echilibrate (13).

Descoperirea unor noi sindroame şi identificarea genelor candidat. În ultimii ani, implementarea aCGH a permis descoperirea de sindroame plurimalformative determinate de microdeleții sau microduplicații cromozomiale. Majoritatea acestor anomalii sunt nedetectabile prin cariotip clasic sau se găsesc în regiuni genomice pentru care nu au fost produse sonde FISH specifice. Utilizarea aCGH pe loturi mari de pacienți a facilitat descrierea unor noi sindroame printr-o „dismorfologie inversă", în care descoperirea anomaliei citogenetice precede definirea fenotipului corespunzător (10). Practic, după analizarea rezultatelor şi definirea unei regiuni cromozomiale absente/ duplicate la un grup de pacienți, fenotipurile acestora sunt comparate pentru a determina trăsăturile clinice esențiale, pe baza cărora pot fi identificați ulterior alți pacienți cu aceeaşi anomalie.

Capacitatea aCGH de a detecta dezechilibre cromozomiale mici facilitează şi identificarea genică. De exemplu, gena CHD7 (implicată în sindromul CHARGE) a fost localizată prin identificarea prin aCGH a două microdeleții suprapuse parțial, la doi pacienți cu sindrom CHARGE (25).

CONCLUZII

Datorită identificării precise a anomaliilor genomice cantitative, cu o rezoluție înaltă şi un „debit" mare, aCGH a revoluționat diagnosticul genetic şi a oferit noi informații pentru elucidarea structurii şi funcției genomului uman în stare normală şi patologică. Tendința actuală în cercetarea genetică este aplicarea pe scară cât mai largă a metodei aCGH, dar utilizarea ei în scop diagnostic rămâne încă limitată de prețul prohibitiv al aparaturii şi consumabilelor. Totuşi, fiind mai rapidă şi având o rezoluție mai mare decât tehnicile de citogenetică moleculară, aCGH va înlocui în mod cert unele dintre aceste tehnici atunci când laboratoarele vor fi dotate cu aparatura necesară.

PRESENT AND FUTURE OF RECOMBINANT VACCINE TECHNOLOGIES (Abstract): Vaccination still has the potential to make a bigger contribution to global health. The routine uses in industrialized countries of hepatitis B and human papillomavirus vaccines successfully marked the prevention of liver and cervical cancer, is a very good example. All technological and scientific acquisitions in recombinant DNA technology over the last few years have resulted in new vaccines, thus making vaccination available to an increasing number of patients. Some recombinant vaccines have been already approved for medical use and others are in different stages of preclinical or clinical evaluation. Nowadays, novel approaches are being explored, such as: reverse vaccinology, bioconjugation technology, the use of generalized modules for membrane antigens and the use of RNA vaccines. By modifying the genome of the agents of infectious diseases new vaccines, safer, more effective, lower cost and convenient delivery, will emerge. **Keywords:** RECOMBINANT VACCINES, DNA TECHNOLOGY, RECOMBINANT VECTORS, SUBUNIT VACCINES.

One of the milestones of modern medicine is undoubtedly the vaccines that saved the lives of millions of people. The experience of the last 200 years has shown that the discovery and use of vaccination on a world scale has surpassed in efficiency the discovery of antibiotics or other inventions and achievements in the medical field. Thus, in some countries, because of systematic immunization, there was a significant reduction in morbidity and mortality from diphtheria, tetanus, pertussis, measles, rubella, or yellow fever (1).

Effective vaccines must induce immunity without pathogenesis. In other words, this is done either by attenuating or inactivating viral or bacterial pathogens, or by using the toxin or subunit components of the pathogen. The success of a vaccine depends both on the stability of the antigen and on its ability to stimulate or cause immunological memory (2).

Generally, all these strategies highlight their advantages and disadvantages and

their use depends on knowing the mechanisms of infection of the target pathogen and the immune response required for protection.

This paper will present new approaches in recombinant DNA technology for vaccine development.

A VERY SHORT HISTORY

At the beginning of the 20th century five human vaccines were used: smallpox, rabies, typhoid, cholera and plague vaccines. The golden age in vaccine development began after the World War II, when at least 23 vaccines were discovered and used (1, 2, 3).

In 1986, the first recombinant hepatitis B vaccine was licensed in the United States. Another important moment was the authorization of the recombinant human papillomavirus vaccine (HPV) in 2006. Since then other recombinant vaccines are available. The recombinant human vaccines development is presented in Table I (1).

TABLE I
Development of recombinant human vaccines

Type of genetically engineered vaccines	Approval year
Hepatitis B surface antigen recombinant	1986
Cholera (recombinant toxin B)	1993
Lyme OspA *(withdrawn)*	1998
Human papillomavirus recombinant (quadrivalent)	2006
Human papillomavirus recombinant (bivalent)	2009
Meningococcal group B proteins	2013
Pertussis toxine subunit 1 recombinant (monovalent)	2016
Zoster, adjuvanted (recombinant subunit)	2017

Recombinant vaccine development

Advances in molecular genetics and genetic engineering have made possible the identification of genes encoding the synthesis of certain antigenic proteins. The emergence of recombinant DNA technology has assured extensively the production of polypeptides normally present on the surface of certain pathogens (then used as subunit vaccines).

Some recombinant vaccines have been already approved for medical use (vaccines against hepatitis B monovalent or in combination with other antigens, cholera, human papillomavirus, group B meningococcal disease, *Bordetella pertussis*, herpes zoster) and others are in different stages of preclinical/clinical evaluation, as it can be seen in table II (3).

Vaccine development using recombinant DNA technology requires an in-depth knowledge of the antigens that will induce protection. It is also important to understand the host immune response to ensure that the vaccine induces an adequate immunological response.

Recombinant vaccines can be classified as follows (1, 3):

- live genetically modified vaccines;
- inactivated (subunit) recombinant vaccines;
- genetic (DNA) vaccines.

TABLE II

Recombinant vaccines development stage

Type of vaccines		Examples	Development stage	
			Preclinical or clinical evaluation	Approved
Live vaccines	Recombinant virus	Herpes simplex virus	X	
		Poliovirus	X	
	Recombinant viral vector	HIV	X	
		Ebola virus	X	
		Cytomegalovirus	X	
	Recombinant bacteria	*Vibrio cholerae*	X

Live genetically modified vaccines

This category includes recombinant viruses, recombinant bacteria and recombinant viral and bacterial vectors (3).

Recombinant viruses. In the viral genome specific changes or gene deletions can be made so that the virus will be more attenuated and stable. Thus, by deleting the gene encoding a glycoprotein responsible for pathogenicity of the herpes simplex virus (HSV) a non-replicating HSV strain was obtained, which can initiate infection *in vivo* without being able to replicate. Polioviruses with unoptimized codons in the capsid region produce more attenuated viruses which stimulate the production of antibodies.

Recombinant bacteria. The attenuation strategy consists in deletion of genes responsible for bacterial virulence or modulation of their expression *in vivo*. By attenuation of *Vibrio cholerae* strains live vaccines against cholera were developed. The attenuation was performed by deletion of genes encoding virulence factors (cholera toxin). There have been attempts to develop *Shigella* strains in live vaccines by certain chromosomal or plasmid gene mutations to reduce pathogenicity.

Recombinant viral vectors. The purpose of creating such vectors is to stimulate the immune system to respond to the antigen in the context of a live virus infection. The viral vector vaccinia virus could express human immunodeficiency virus type 1 (HIV-1) by glycoprotein 160. The fowlpox and canarypox viruses had been developed recently as live viral vectors for use in humans. Adenovirus, one of the most potent vector was designed to express foreign polypeptides particularly for HIV and hepatitis C virus (HCV). Another viral vector is alphavirus which can express cytomegalovirus glycoprotein (CMV), being developed as a candidate for CMV vaccine.

Recombinant bacterial vectors. Important for these vectors is to retain sufficient virulence for replication and to express foreign polypeptides to elicit an immune response against pathogens. *Salmonella typhi* vectors are the most used strains, and the strains of *Vibrio cholerae*, *Shigella flexneri*, *Listeria monocytogenes* and BCG vaccine strain were engineered as a live vector for clinical assessment.

Subunit recombinant vaccines

The use of recombinant polypeptides as subunit vaccines is the most widely applied and accepted reliance of recombinant DNA technology for the development of modern vaccines. Subunit vaccines are effective for some pathogens but have poor immunogenicity, thus more doses with higher amounts of antigen are required.

Virus-like particles. The assembly of proteins as virus-like particles (VLPs) was a major progress. The proteins are expressed in yeast, insect, plant or mammalian cells. VLPs, which lack the viral genome, are a highly effective type of subunit vaccines that elicit strong humoral and cellular response and are a much safer alternative.

The first application was hepatitis B surface antigen (HBsAg) obtained by expressing the gene in *Saccharomyces cerevisiae*. The recent trend is to express the gene in transgenic plants (potato tubers, tobacco plants etc.) (4, 5).

Another example of efficient use of VLPs is the L1 protein of HPV obtained by expressing the gene in insect cell lines (*Spodoptera frugiperda*, *Trichoplusia ni*) or in *Saccharomyces cerevisiae* cells after infection with recombinant baculoviruses

(*Autographa californica)* (6).

Natural sequences. The outer surface protein A (OspA) of *Borrelia burgdorferi* expressed in *E. coli* as recombinant protein was approved for Lyme disease prophylaxis (the vaccine was later withdrawn from the market). Recombinant HSV glycoproteins derived from Chinese hamster ovary (CHO) cells and recombinant HIV-1 glycoprotein 120 expressed in CHO cells were clinically evaluated.

Fusion proteins. Recombinant fusion proteins were expressed as multi-epitope peptide vaccines targeting multiple antigens. Fusion proteins from *Neisseria meningitidis* serogroup B, *Streptococcus pneumonia, Streptococcus pyogenes* group A have been evaluated in clinical studies (7, 8).

Noninfectious disease. Nowadays, clinical trials evaluate the utility of vaccines in such noninfectious diseases as diabetes, cancer, allergy etc.

Genetic vaccines

DNA vaccination means that the antigenic molecule is produced in the host by injecting DNA. The antigen encoded gene is linked to a plasmid together with a strong mammalian promoter and then transfected cells express the antigen resulting in an immune response.

"Naked" DNA. A naked DNA encoding a vaccine antigen is injected so cells synthesize an antigen and an immunologic response is induced. Naked DNA vaccine for influenza is in clinical trials and the obtained data are promising. Recently, plasmids encoding HCV NS3/4a (ChronVac-c) (hepatitis C virus) were identified as potential therapeutic vaccines for HCV in animal models (9).

"Facilitated" DNA. To increase cellular uptake of DNA this molecule can be incorporated into microprojectiles and shot into cells via a gene gun ballistic device or coated into gold microparticles and delivered into the epidermis with a needle-free device or coated with cationic lipids which facilitate transport across membranes. These DNA vaccines may be useful in hepatitis B, cancer, flu, SIDA etc.

DNA viral delivery. The poxvirus family (fowlpox virus, canarypox virus) can deliver DNA in avian cells, mammalian cells to express the recombinant protein (10, 11).

DNA bacterial delivery. Some attenuated bacterial species can deliver DNA into mammalian cells for expressing vaccine antigens. A strain of *Shigella flexneri* is in preclinical studies to deliver recombinant plasmids in mammalian cells (12).

NOVEL APPROACHES

A novel approach to produce new vaccines is the use of reverse vaccinology which involves sequencing the genome of a target pathogen and scanning for genes to select the best vaccine antigens by in silico approaches may be useful to obtain new vaccines (13, 14).

Another way to develop vaccines is the bioconjugation technology. Recently, a phase I study revealed that a novel bioconjugate vaccine against *Shigella flexneri* 2a (containing polysaccharide of the *Shigella flexneri* 2a O-antigen conjugated to the exotoxin protein A of *Pseudomonas aeruginosa)* elicit a robust humoral response and induce functional antibodies (15).

The use of Generalized Modules for Membrane Antigens (GMMA) for the development of vaccines against bacterial pathogens is another affordable technology. The production of outer membrane vesicles can be enhanced by genetic muta-

tion which leads to the production of GMMA. A phase II trial evaluated a *Shigella sonnei* vaccine based on GMMA as a delivery system for *Shigella sonnei* O antigen which proved to be highly immunogenic and well tolerated (16).

Finally, is the use of RNA vaccines, both synthetic mRNA and self-amplifying RNA to induce an immune response. Synthetic mRNA encoding only the protein of interest has an immediate translation of the antigen eliciting a good antiviral protection (17, 18). Self-amplifying RNA is virally derived, encodes the antigen of interest and proteins enabling RNA vaccine replication and induces an immune response (19, 20).

CONCLUSIONS

Our study revealed that recombinant vaccines are designed to be safer and more effective than traditional vaccines. By modifying the genome of infectious agents' new vaccines with higher costs will emerge, which will be a major challenge to developing countries.

All the technological and scientific acquisitions in recombinant DNA technology over the last few years have resulted in new vaccines, thus making vaccination available to an increasing number of people. The benefits to society are population immunity, prevention of epidemics and reduction of costs associated with medical care.

NEWS

IMPACT OF ACUPUNCTURE IN POLYCYSTIC OVARY SYNDROME

This randomized clinical trial compares the effect of true acupuncture with metformin and sham acupuncture on the insulin sensitivity of women with polycystic ovary syndrome. The study lasted 4 months, and included 3 days per week of true acupuncture (profound needls stimulated manually and electrically) or sham acupuncture (superficial needles without manual or electrical stimulation) and 3 times per day metformin or placebo. The primary objective of the study is to demonstrate that the treatment with true acupuncture and metformin placebo improves insulin sensitivity. Some protocols have been used in the treatment application: regular physical exercise, a balanced diet, fixed acupuncture protocols, and measurements have been applied that have been statistically analyzed to determine the efficacy of the treatments. Finally, it was confirmed that true acupuncture which combines Electrical and Manual Acupuncture improves insulin sensitivity, hormone levels and anxiety in patients with PCOS. (Li J, Hung Yu Ng E, Stener-Victorin E *et al*., Acupuncture treatment for insulin sensitivity of women with polycystic ovary syndrome and insulin resistance: a study protocol for a randomized controlled trial. *Trials*. 2017; 18: 115).

HIGH-RESOLUTION RESPIROMETRY WITH MULTIPLE SUBSTRATES TITRATION IN PERMEABILIZED MYOCARDIAL FIBERS (Abstract): The present study was purported to standardize the high-resolution respirometry technique for the analysis of oxidative phosphorylation (OXPHOS) in saponin-skinned cardiac fibers. Preparation of permeabilized myocardial fibers allows the assessment of respiratory function of the entire population of mitochondria in their normal intracellular position. Adult male rat ventricular bundles were permeabilized with saponin (50 µg/ml) and samples (1-3 mg wet weight) were transferred into the Oxygraph-2k (OROBOROS Instr., Austria) chambers containing air saturated incubation buffer in order to measure Complex I (CI) and II (CII) dependent respiration. The following values (expressed in pmol $O_2 \cdot s^{-1} \cdot mg^{-1}$) were obtained: CI_LEAK, 67.18±5.12 (CI dependent basal respiration, after glutamate and malate addition); CI_P, 247.37±49.90 (CI_OXPHOS state after ADP addition); CI_Pc, 252.036±53.13 (the intactness of the outer mitochondrial membrane assessed after cytochrome *c* addition); CI+II_P, 342.90±62.48 (maximum OXPHOS state obtained after succinate addition by activating convergent electron flow from CI+II into the Q junction of the electron transport system (ETS); CII_P, 302.26±50.16 (CII dependent OXPHOS state obtained after the addition of a CI inhibitor - rotenone, with the subsequent entry of electrons from CII only into the Q junction); ETS capacity, 331.11±62.39 (uncoupled respiration). The standardized technique will allow the systematic characterization of mitochondrial respiratory dysfunction associated with several cardiac pathologies in both animals and humans. **Key words:** HIGH-RESOLUTION RESPIROMETRY, PERMEABILIZED MYOCARDIAL FIBERS.

Cardiovascular diseases and coronary heart disease, in particularly, remain the leading cause of mortality due to myocardial infarction and morbidity due to heart failure worldwide. Mitochondria are recognized to be directly involved in pathophysiology of ischemia-reperfusion injury (1-3) and also in cardioprotection (4). In the past decades, analysis of mitochondrial respiratory (dys)function has become a common research tool in basic cardiology, and strategies able to reversibly modulate respiration in order to protect mitochondria during the postischemic reperfusion are widely investigated (5).

The present study was aimed to standardize the technique for preparation of permeabilized fibers from rat hearts view subsequent studies of high-resolution respirometry (HRR). Standard procedures of

mitochondria isolation based on differential centrifugation allow precise characterization of several mitochondria functions (6). However, one of the most important drawbacks of this technique is related to the fact that some of these functions (including the respiratory one) are impaired by the isolation steps; these effects can be even more pronounced in mitochondria isolated from tissue damaged by a pathological process, such as ischemic injury as well as other cardiac pathologies (6).

At variance from the classical method of differential centrifugation, in saponin-skinned cardiac fibers, intracellular structures (cytoskeleton, contractile apparatus) are well preserved and the morphological appearance of mitochondria is similar to the one *in vivo* (7). Last but not least, the latter method uses only small amounts of tissue (1-3 mg wet weight) making it particularly useful for human studies (8).

MATERIAL AND METHODS

1. *Principle of selective plasma membrane permeabilization*

Cholesterol-complex forming agents such as saponin interact with cholesterol molecules which are abundantly present in plasma membrane. This interaction induces a loss of membrane integrity (permeabilization) and the barrier between the intracellular space and surrounding medium disappears (9). Since the cytosol is washed out, the composition of the intracellular space is equilibrated with the experimental incubation medium (10). Mitochondria cholesterol content is considerably low (11, 12) and the cholesterol-complex-forming agent in the concentration used for cell membrane permeabilization does not disrupt these organelles, allowing thus investigation of their function (Fig.1).

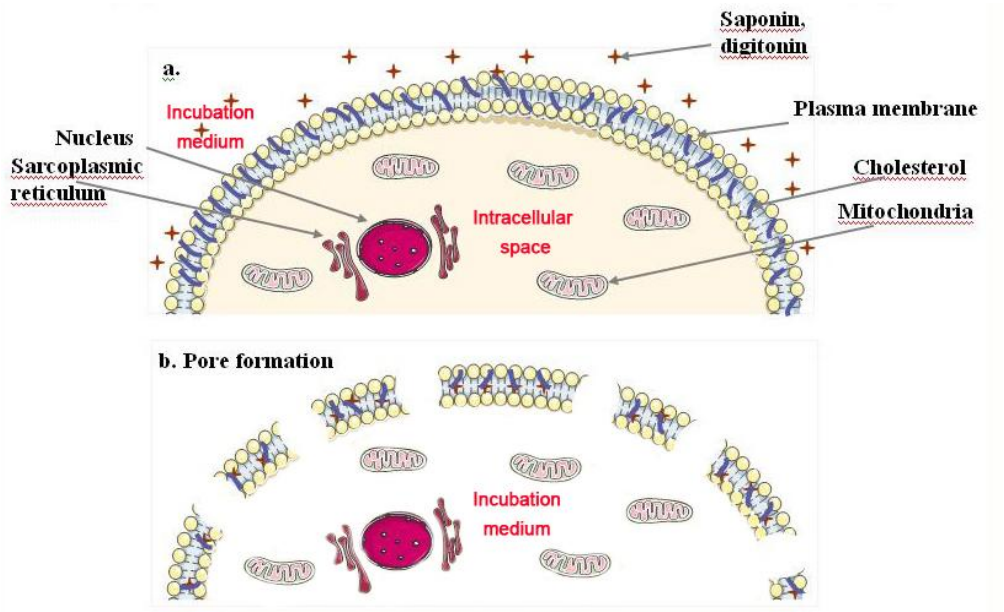

Fig. 1. Principle of selective plasma membrane permeabilization: (a) cells before and (b) after treatment with saponin. (Figures were produced using *Servier Medical Art*)

2. Preparation of permeabilized rat myocardial fibers

All investigations conformed to the Directive 2010/63/EU on the protection of animals used for scientific purposes and were approved by the Ethics Committee of our university.

Adult male rats (n=12, 250-350 g) were anesthetized with xylazine (5 mg/kg) and ketamine (30 mg/kg) I.P. Hearts were rapidly excised and immersed in the isolation buffer containing 10 mM Ca-EGTA buffer, 0.1 μM free calcium, 20 mM imidazole, 20 mM taurine, 50 mM K-MES, 0.5 mM DTT, 6.56 mM $MgCl_2$, 5.77 mM ATP, 15 mM phosphocreatine (pH 7.1 adjusted with 5 N KOH at 0°C). Atria were discarded and ventricular muscle strips were further dissected into the ice-cold buffer to form thin bundles (a period of maximum 4 minutes is required for the preparation of fiber bundles, thus avoiding damage to the external mitochondrial membrane). The ventricular tissue should remain connected in a mesh-like framework (Fig. 2 A and B).

The fiber bundles were further transferred into ice-cold isolation buffer, containing 50 μg/ml of saponin stock solution (5 mg/ml) and shaken by gentle agitation on ice for 30 min (13). After this period, all samples were transferred into the incubation buffer (0.5 mM EGTA, 3 mM MgCl2.6H2O, 60 mM K-lactobionate, 20 mM taurine, 10 mM KH2P04, 20 mM HEPES, 110 mM sucrose, 1 g/l BSA, essentially fatty acid free, pH = 7.1, at 30 °C + 280 U/ml catalase lyophilized powder, 2,000-5,000 units/mg protein H2O2) and further gently shaken for 10 min on ice (in order to wash out the saponin excess). Fiber bundles were then weighted (optimal amount in the oxygraph chamber for one experiment is between 1-3 mg wet weight) (14).

3. Measurements of respiratory rates by high resolution respirometry

At the beginning of the experiment oxygen sensors were calibrated with MiR06 at experimental temperature in the "open" chamber (gas phase above the stirred medium, with a partially inserted stopper) of the Oxygraph-2k (Oroboros Instruments, Innsbruck, Austria). Samples were quickly transferred into the Oxygraph-2k chambers containing air saturated incubation buffer. Respiratory flux of muscle fiber bundles is limited by oxygen diffusion even above 50% air saturation (O_2 concentration of 100 μM) (15). Other authors also recommended the prevention of the oxygen limitation in permeabilized fibers experiments by maintaining oxygen levels in the chamber in the range of 200–500 μM (14, 16). In our experiments we used a high-oxygen regimen: before closing the chamber, the oxygen concentration was increased to 300–400 μM, by injecting pure O_2 through the stopper. Five to ten minutes were required for stabilization of the signal. During the recording period, we prevented oxygen drop below 200 μM by intermittent H_2O_2 titrations (100 μM).

Substrate combinations that match physiological intracellular conditions were applied for the evaluation of coupling control, OXPHOS and ETS capacity at 37°C, respectively. The Substrate-Uncoupler-Inhibitor Titration (SUIT) protocol used was as follows: Addition of glutamate and malate as complex I (CI) substrates – a step referred as basal respiration (the classical state 2) or CI_LEAK state (CI_L); Addition of ADP to activate oxidative phosphorylation (OXPHOS) – a step known as active respiration (the classical state 3) and is further referred as CI_OXPHOS state (CI_P); Cytochrome c addition to assess the intactness of the outer mitochondrial membrane (CI_Pc). Mitochondrial integrity may become compromised during mechanical separation of fibers, resulting in damage to the outer membrane and release of cytochrome c which then becomes a limiting factor in mitochondrial respiration. Since cytochrome c cannot penetrate an intact outer mitochondrial membrane, addition of exogenous cytochrome c represents a quality control measure of mitochondrial integrity (17). The absence of an increase of respiration rate after adding 5-32 μM cytochrome c indicates a high quality preparation; Succinate, a complex II (CII) substrate addition to further stimulate the respiration by activating convergent electron flow from CI+II into the Q junction, a step referred as maximum CI+II OXPHOS capacity (CI+II_P); Rotenone (CI inhibitor) addition to measure OXPHOS state with entry of electrons from CII only into the Q junction (CII_P); ATP synthase inhibition with oligomycin (Omy); Uncoupled respiration obtained by FCCP titration, a step known as Electron Transport System capacity (ETS); Inhibition of respiration with antimycin A (Ama), a state referred to as Residual OXygen capacity (ROX state).

Most of the chemicals were purchased from Sigma-Aldrich and were used without further purification. Results are expressed as means ± S.D.

RESULTS AND DISCUSSION

Twelve animals were used and a number of 4 tracings were recorded for each animal according to the above mentioned protocol. Each day 2 animals were sacrificed in order to perform respirometry measurements. No significant differences were found among the daily values for respiration states and RCR, respectively (*p*

> 0.05, ANOVA).

A representative tracing of the SUIT protocol for high-resolution respirometry (HRR) measurements in permeabilized fibers is depicted in Figure 3.

Our results showed the following values for basal, CI_L, 67.18 ± 5.12 pmol $O_2 \cdot s^{-1} \cdot mg^{-1}$ wet weight and, active respiration, CI_P, 247.37 ± 49.90 $O_2 \cdot s^{-1} \cdot mg^{-1}$ wet weight, respectively. Respiratory control ratio (RCR), a good parameter indicating the coupling between oxygen consumption and oxidative phosphorylation was further calculated as the ratio between OXPHOS and LEAK respiration rates. Accordingly, RCR for NAD-linked substrates was 3.65±0.51, values similar to the ones reported in literature (9, 18, 19).

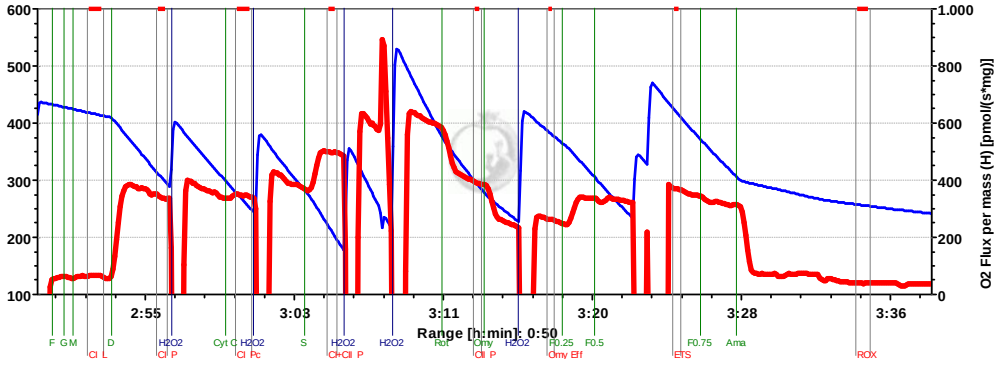

Fig. 3. Original trace of a SUIT protocol in permeabilized cardiac fibers

Oxygen concentration (upper line, left scale) and O_2 flux per mass (lower line, right scale) are represented as a function of time. The additions are as follows:

G – glutamate (10 mM), **M** – malate (0.2 mM), **D** – ADP (5 mM), **Cyt C –** cytochrome c (10 µM), **S** – succinate (10 mM), **Rot** – rotenone (0.5 µM), **Omy** - oligomicin (2 µg/µl), **F** – FCCP titration in steps of 0.5 µM optimal concentration, **Ama** – antimycin A (2.5 µM).

The addition of cytochrome *c*, used as validation of proper tissue preparation, showed an increase with 1.88 ± 6.47 % (CI_Pc, 252.036 ± 53.13 pmol $O_2 \cdot s^{-1} \cdot mg^{-1}$ wet weight), values that are also in agreement with data reported by other researchers; slight elevations in respiratory rates of 5–15% are considered acceptable (8). However, in ischemia/reperfusion experiments an increase in respiration rates after cytochrome *c* addition due to the damage of mitochondria especially during postischemic reperfusion is generally admitted (20, 21). Indeed, the damage of the outer mitochondrial membrane represents an early event in ischemia/reperfusion injury of the heart (20, 22).

In classic respirometry experiments, conventional measurements of state 3 with either NAD+ (CI) or FAD (CII) linked substrates, were reported to underestimate OXPHOS capacity (23). Therefore, in our experiments of HRR, in order to obtain the maximal ADP-stimulated mitochondrial capacity, we measured respiration depending on both CI and CII, by adding succinate immediately after cytochrome *c* (CI+II_P, 342.90 ± 62.48 pmol $O_2 \cdot s^{-1} \cdot mg^{-1}$ wet weight). Establishing the maximum cou-

pled respiration state provides the proper basis for the evaluation of specific enzymatic defects in mitochondrial respiratory physiology and pathology (23).

Inhibition by rotenone determined a decrease in OXPHOS capacity since the electron input is through CII exclusively (CII_P, 302.26 ± 50.16 pmol $O_2 \cdot s^{-1} \cdot mg^{-1}$ wet weight). Addition of oligomycin (which blocks the proton channel of ATP synthase, thus inhibiting ADP phosphorylation) was used not only to check alterations in LEAK respiration, but also the integrity of the inner mitochondrial membrane that could eventually be damaged during the mechanical preparation of fibers (8). Sensitivity of oxygen to oligomycin suggests the intactness of the inner mitochondrial membrane (Fig. 3).

Uncoupled respiration was obtained by stepwise titration of carbonyl cyanide-p-trifluorocarbonyl-cyanide methoxyphenyl hydrazone (FCCP) with an ETS value of 331.11 ± 62.39 pmol $O_2 \cdot s^{-1} \cdot mg^{-1}$ wet weight. Increments in O_2 flux above CII_P indicates a limitation in respiratory capacity by ATP synthase, adenine nucleotide translocases or phosphate transporters since under the effect of FCCP, mitochondrial oxidative capacity through complex II can be determined in the absence of the potential control exerted by all of these (24).

The limitations of the present technique are briefly mentioned. During the permeabilization process the cytosolic components of the cardiac fibers which regulate mitochondrial function are lost, resulting in the inability to assess mitochondria in an exact *in vivo* environment; however, this limitation is also encountered in experiments using isolated mitochondria. *In situ* mitochondrial respirometry assesses the total mitochondrial population without distinguishing between the two subpopulations (subsarcolemal and interfibrillar) that can be separated by successive centrifugations and are reported to be differentially affected by ischemia/reperfusion injury (8). Another important issue which must be taken into consideration in order to compare different literature data is that respiratory measurements may be expressed per wet weight or dry weight. We have chosen to express our data in wet weight, since fiber wet weight is easily measured before their addition into the Oxygraph chamber, while measurement of dry weight depends on the complete recovery of the samples after the experimental measurements (23).

CONCLUSIONS

We have standardized for the first time in our country the high-resolution respirometry technique in saponin-permeabilized cardiac fibers. The utilization of HRR according to the SUIT protocol is a highly reproducible method that allows the systematic assessment of mitochondrial respiratory function while cellular architecture is preserved. This method will be further used to characterize abnormalities in mitochondrial function in both animal and human cardiac pathologies and, also to investigate the effects of cardioprotective interventions.

ACKNOWLEDGMENTS

We acknowledge support from the National Authority for Scientific Research grant 42-122 and the Hungarian-Romanian Cross-Border Cooperation project HU-RO/0901/137/2.2.2. O.D. and D.G. are supported by the POSDRU Fellowship Project 1.5/88/S/ID 63117 and benefited from training within the STSMs of the COST action FA0602.

REACTION TIMES (RTs) AND COGNITIVE VISUAL EVOKED POTENTIALS DURING READING – A COMPARED STUDY (Abstract): **Objective**: The main aim of the experiment is to prove the Paivio's theory about the concrete-abstract effect. **Methods**: A psycho-verbal stimulation interface, created by us, was experimented as an IT extension of an *EEG / EMG device* dedicated for the human brain Evoked Potentials acquisitions *(EPs)* and reaction times techniques in reading mechanisms assessment. **Results**: The shortest reaction time was achieved in tests at which the reading has no access to the meaning of words, for concrete word, in both hemisphere. But, in left hemisphere the reaction times for abstract words was shorter than for the abstract word in right hemisphere. EPs acquisition exhibits more negativity of N400 for concrete word and more reverberation of P650 – N750 for abstract words. **Conclusions**: The difference in mean reaction times sustain the Paivio's theory and the difference in amplitude of N400, P650-N750 for concrete and abstract nouns show that the electric activities of brain are correlated in time and in amplitude with the same effort of processing the words. The psycho-verbal stimulation interface can be used as a medical research tool for studying and assessment the cognitive processes of reading, memory or learning using the endogenous visual event related potentials and the psychometric reaction times.
Key words: PSYCHO-VERBAL VISUAL EVOKED POTENTIALS (EPs), PSYCHOMETRIC REACTION TIMES (RTS), READING PROCESS.

În domeniul psiho-lingvistic s-au făcut o serie de determinări în timpii de reacţie psihometrici, privind procesarea informaţiei vizuale şi auditive în funcţie de parametrii psihologici individuali şi de dezvoltarea neuropsihică. Metoda determinării vitezei de reacţie psihometrice a fost folosită de asemenea în evaluarea performanţei sportive şi ca metodă de antrenament încă din anii '50. Metoda nu oferă totuşi o evaluare obiectivă a performanţei de procesare senzorială, datorită implicării lanţului motor în răspuns. Timpul de reacţie nu a putut oferi date directe privind mecanismul neuropsihic al procesării informaţiei lexicale, a mecanismului recunoaşterii, memoriei şi nici a mecanismelor patolingvistice implicate în afectarea limbajului, în special în afazii (1).

Apariţia tehnicii de potenţiale evocate a reprezentat un moment de cotitură în evaluarea neinvazivă a integrităţii analizatorilor. Totuşi, metoda în varianta clasică, utilizând stimuli nediferenţiaţi, nu dă date privind procesarea sensorial-semantică a in-

formației (2).

În anii ‘80 - 90, utilizarea stimulilor cu încărcătură semantică (imagini, cuvinte) au permis corelarea unor componente tardive ale potențialelor evocate - P300, N400 cu procesarea psihică a informației recepționate vizual. Tehnica, deşi nu are standarde de implementare clinică, este în prezent folosită în cercetarea proceselor neurocognitive, pentru buna rezoluție temporală a procesării stimulului cognitiv şi, alături de tehnicile neuroimagistice PET, SPECT, constituie instrumentele de bază pentru desluşirea mecanismelor limbajului, memorie şi învățării (3).

Teoria codificării duale a informației a lui Paivio (1971, 1986, 1991), postulează existența unor sisteme distincte de procesare a stimulilor verbali şi neverbali, dar interconectate funcțional şi probabil anatomic (4). Conform teorii codificării duale, toți stimulii verbali concreți sau abstracți sunt inițial procesați de un sistem unic de reprezentare verbală. Cuvintele concrete au acces la ambele sisteme: în sistemul de asociație verbală, cât şi în sistemul de asociație non-verbal. De aceea, cuvintele concrete generează cu uşurință imagini mentale. Cuvintele abstracte au în special conexiuni asociative doar în sistemul verbal şi de aceea nu generează cu uşurință imagini mentale. Implicarea celor două sisteme în decodificare, şi prin aceasta, şi în reprezentarea semantică, determină o performanță superioară de procesare a cuvintelor concrete în teste ce impun recunoaşterea sau evocarea - redarea semantică a informației (5). Teoria nu face precizări privind distribuția celor două sisteme în creierul uman (6). Obiectivul experimental a fost demonstrarea existenței unor structuri şi mecanisme cerebrale distincte în procesarea diferitelor categorii lexicale şi gramaticale în zone cerebrale diferite, exprimată în determinările timpilor de reacție şi componentele tardive N400, P650, N720 a potențialelor evocate vizual printr-o metodă în premieră în România. Originalitatea metodei a fost utilizarea stimulilor psiho-verbali în culegerea potențialelor evocate, corelată cu determinarea vitezei de reacție printr-o interfață hardware-software de concepție personală.

MATERIAL ŞI METODĂ

Studiul a fost efectuat pe un lot de 20 de persoane dreptace, cu studii superioare, cu vârste între 20 şi 40 de ani, cu abilități lexicale şi vizuale integre. Persoanele au fost selecționate prin discernământ voluntar şi au fost plătite pe perioada experimentului. La înscrierea în experiment, fiecare participant a prezentat o adeverință de la specialistul oftalmolog privind integritatea funcției vizuale şi a completat un chestionar care a probat calitățile de dreptaci. Comisia de etică universitară a aprobat experimentul prin faptul că este neinvaziv şi nu implică modificări ale discernământului, ale stării de sănătate sau de conştiență a indivizilor testați.

Metodele folosite au fost de stimulo-detecție a timpii de reacție psihometrici şi a potențialelor evocate vizuale cognitive, utilizând o interfață de stimulare psiho-verbală concepută şi brevetată, conectată la un aparat EMG - MYTO I – EBNeuro. Stimularea s-a realizat cu 500 de cuvinte cu frecvență lexicală crescută, fără domeniu specific, prezentate 1000 ms, pauză 1000 ms, font 120 galben pe fond negru, expunere stabil reperată (colț stânga-jos ecran) la 60 cm la nivelul central al câmpului vizual (fig.1). S-au folosit 8 liste-cuvinte integrate aleator (4 liste pentru timpii de reacție şi 4 liste pentru achiziția de potențiale evocate)

pentru fiecare din cei 20 de subiecți (10 bărbați şi 10 femei): în listele 1 - 4 s-au folosit substantive concrete imaginabile, iar în listele 5- 8 au fost introduse substantive abstracte neimaginabile. Timpii de reacție au fost determinați prin stimulare în hemicâmp vizual, iar potențialele evocate cognitive s-au înregistrat prin stimulare binoculară.

Montajul şi setările achiziției au fost următoarele: electrozii referință (+) Cz, activul (-) Oz, *ground nasion*, înregistrare pe 4 canale, sensibilitate canal 2 μV, filtre cut-down 10 Hz, cut-up 3kHz, *sweep* 100 ms, impedanța electrozi < 10 kΩ, achiziție prin mediere coerentă

Fig. 1. Procedura achiziției de potențiale evocate cognitive vizuale

REZULTATE

Determinările s-au efectuat în paralel pentru timpii de reacție şi pentru potențialele evocate. Timpii de reacție s-au efectuat în hemicâmp vizual şi au fost comparați ca timpi de reacție medii. S-a determinat media lor la cuvinte concrete, abstracte, şi mediile timpilor de reacție la cuvintele cu 1- 4 silabe (7).

Determinările în potențiale evocate au vizat identificarea componentelor tardive P300, N400, P650, N720 şi studiul comparativ în latență, durată şi amplitudine în stimulare cu cuvinte concrete şi abstracte.

Sarcina subiectului în efectuarea testului a vizat accesul semantic lexical prin identificarea cuvintelor cu apartenență categorială (ex. cuvinte exprimând *ustensile*) şi lipsa accesului semantic lexical prin testul de identificare literală.

S-au obținut următoarele diferențe în timpii de reacție medii: timpii medii de reacție sunt mai buni în lipsa accesului lexical; sunt direct proporționali cu numărul silabelor; viteza medie de reacție la cuvintele concrete a fost mai bună decât la cuvintele abstracte. Un procent de 20% din timpii de reacție la cuvintele concrete sunt mai mari decât cei la cuvintele abstracte şi acest fapt s-a observat în cazul cuvintelor cu frecvență lexicală redusă. În privința determinărilor în hemicâmp vizual, timpul de reacție mediu la cuvintele concrete din hemicâmpul vizual drept este sensibil egal cu cel de la cuvintele abstracte în hemicâmpul vizual drept. Viteza de reacție medie la cuvintele abstracte din hemicâmpul vizual drept este mai bună decât cea de la cuvintele abstracte în hemicâmpul stâng (*idem Day 77*). Timpul de reacție mediu la cuvintele concrete în hemicâmpul vizual stâng este sensibil egal cu timpul de reacție mediu la cuvintele concrete în hemicâmpul vizual drept. Valorile la cuvintele concrete sunt mai mici decât cele de la cuvintele abstracte în hemicâmpul vizual stâng (tab. I) (*idem Chiarello, Senehi & Nuding 1987*) (2).

TABELUL I

Timpii de reacție medii

Timp reacție	***Cuvinte concrete***	***Cuvinte abstracte***
Emisfer drept	370 ms ± 20 ms	490 ms ± 30 ms
Emisfer stâng	380 ms ± 20 ms	390 ms ± 35 ms

Din punct de vedere statistic există puternice diferenţe semnificative între timpul de reacţie la cuvinte abstracte în emisferul drept faţă de cuvintele concrete din acelaşi emisfer ($p < 0,001$). Comparând aspectul negativităţii N400 se observă că este mai pronunţat în cazul cuvintelor concrete, în schimb pentru cuvintele abstracte sunt mai pronunţate P650 şi N720 la 75% din subiecţii testaţi (fig. 2).

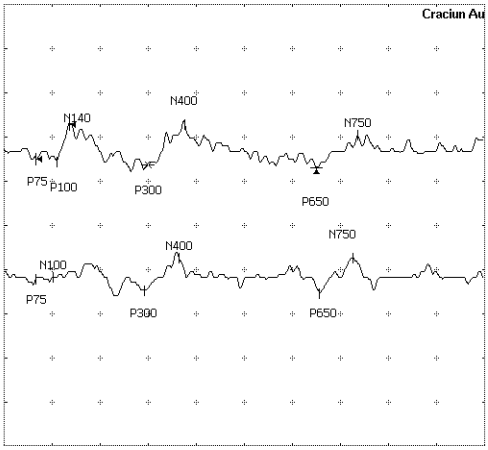

Fig. 2. Potenţiale evocate cognitive la stimularea prin cuvinte concrete (sus) şi prin cuvinte abstracte (jos)

DISCUŢII

Experimentul în timpii de reacţie verifică validitatea teoriei lui Paivio cu privire la procesarea superioară a cuvintelor concrete. Teoria lui Paivio nu oferă o explicaţie de ce cuvintele concrete sunt procesate la fel de bine biemisferic. O ipoteză ar fi că legăturile dintre sistemul non-verbal şi cel verbal ar fi la fel de bine realizate biemisferic încât sistemul verbal permite cuvintelor concrete un acces direct şi o procesare identică biemisferică. Paivio arată că nu concretețea ci imaginabilitatea cuvintelor conferă o performanţă superioară în recunoaştere. Un număr neglijabil de cuvinte concrete au fost cotate puţin imaginabile şi un număr redus de cuvinte abstracte au fost cotate imaginabile. Procesele imaginative sunt generate de ambele emisfere cerebrale, de aceea cuvintele concrete sunt amintite identic când sunt prezentate pe fiecare hemicâmp (1).

Teoria nu explică de ce cuvintele abstracte sunt procesate mai lent de emisferul drept (hemicâmpul stâng) faţă de emisferul stâng. O explicaţie ar fi: cuvintele abstracte au acces iniţial direct doar la sistemul verbal cu localizare predominantă în emisferul stâng, unde conexiunile cu sistemul nonverbal sunt mai puternice, ceea ce permite o procesare mai rapidă pe emisferul stâng şi o specializare pentru procesarea abstractă la dreptaci. Dovezile clinice şi anatomice arată că totuşi în procesele de memorizare şi evocare, rolul primordial îi revine regiunii temporale drepte (hipocamp).

CONCLUZII

Interfaţa de stimulare psiho-verbală este o extensie indispensabilă achiziţiei de potenţiale cognitive. Standardizarea tehnicii impune criterii flexibile adaptate mediului lexical al individului, ceea ce impune colaborarea cu neurolingvişti. Interfaţa de stimulare psiho-verbală asigură posibilitatea studiului proceselor cognitive asociate lexiei, recunoaşterii, memorie şi validitatea unor teorii susţinute de alte tehnici (10).

Studiul în PE a aspectului abstract-concret susţine procesarea diferită a cuvintelor concrete şi abstracte. Cuvintele concrete generează o negativare mai amplă şi de mai lungă durată a lui N400 faţă de cuvintele abstracte (8). Cuvintele abstracte generează reverberaţii tardive la P650 şi N720 (9). Efectul este mai amplu în testele cu acces lexical semantic faţă de cele fără acces (recunoaştere literală). La 25% din subiecţi nu s-a identificat modificările

amintite ceea ce sugerează existența unor *pattern*-uri diferite de procesare, dar nu se exclude posibilitatea culegerilor similare în alte derivații, sau statusul psihologic şi implicarea diferită a subiecților.

Experimentul a arătat că există o corelație între studiile de potențiale evocate şi timpii de reacție în procesarea aspectului concret - abstract. Experimentul nu a vizat studiul lateralității în utilizarea PE, dat fiind lipsa evidențierii lateralității cerebrale în lexie. Se poate confirma existența unor generatori mai extinşi implicați în limbaj (modelul Hebbian), orice *pattern*-ului electric poate avea ca origine diverse configurații ale surselor sau poate fi expresia atenuării prin craniu şi creier a volum - conducerii electrice.

EXPRESSION OF HORMONAL RECEPTORS (α-ESTROGEN, β-ESTROGEN, PROGESTERON), Ki-67 AND P 53 IN ENDOMETRIUM OF TAMOXIFEN TREATED BREAST CANCER PATIENTS (Abstract): Tamoxifen is the most commonly prescribed adjuvant therapy for women with breast carcinoma ER+. It has agonist activity on the endometrium and is associated with an increased risk of endometrial carcinoma. The aim of this study was to evaluate the immunohistochemical changes on the histological endometrial modification from the patients treated with tamoxifen. **Material and method**: A group of 2o women selected from 125 patients with breast carcinoma, with adjuvant therapy. The criteria of selection were the histopathological proliferative changes of endometrium from these symptomatic patients. The 20 specimens of endometrium were evaluate immunohistochemycal by estrogen receptor alpha, beta, progesterone receptor, Ki-67 and P53. **Results and conclusions**: The 20 endometrium specimen showed histological proliferative endometrial lessions, including polyps, hyperplasia and carcinoma. Immunohistochemical, benign lessions showned expression of estrogen α and β receptor, low expression Ki-67 and absent expression of P53. These tests were negative in clear cell carcinoma, but were intens positive for Ki-67 and P53. In general, tamoxifen associated endometrial adenocarcinoma were characterized by a lower expression of estrogen receptor alpha, higher expression of progesterone receptor, and more frecquent expression of estrogen receptor beta than endometrial spontaneous tumors. **Key words**: ENDOMETRIUM, TAMOXIFEN, EXPRESSION OF ESTROGEN RECEPTORS, PROGESTERON, Ki-67, P53.

Prin efectele sale antiestrogenice, tamoxifenul este utilizat ca tratament adjuvant pentru carcinomul mamar cu receptori pozitivi la estrogeni (ER+). Într-un studiu anterior (1) am prezentat modificările endometriale histopatologice curente la 125 paciente simptomatice cu carcinom mamar (ER+).

În acest studiu ne-am propus să evidenţiem expresia receptorilor hormonali: α -estrogen, β – estrogen şi progesteron. De asemenea, prin utilizarea reactivilor Ki-67 şi P 53 am încercat să stabilim tendinţa la proliferare a endometrului de la aceste paciente.

MATERIAL ŞI METODĂ

Din 125 paciente tratate cu tamoxifen, în 20 cazuri, pe secţiunile histologice ale produselor de chiuretaj au foat aplicaţi

reactivi imunohistochimici: receptori α- şi β- estrogeni, progesteron, Ki-67 şi p53.

Toate pacientele au prezentat hemoragii uterine disfuncţionale atât în postmenopauză, cât şi în premenopauză în cursul tratamentului cu tamoxifen de 40 mg zilnic într-o perioadă cuprinsă între 8 şi 72 de luni. Diagnosticul histopatologic a fost precizat pesecţiunile colorate cu hematoxilin-eozină.

Pentru evidenţierea imunohistochimică (IHC) a antigenelor tisulare, metoda utilizată este bistadială, bazată pe un sistem de vizualizare cu reţea polimerică (DAKO EnVision) (tab. I).

TABELUL I

Tehnica imunohistochimica de evidenţiere a antigenelor tisulare

Antigen	Clona	Specificitate	Producător	Diluţie	Pretratament
ER alfa	CloneSP1	nucleii celulelor epiteliale în receptorii de estrogeni α	DAKO, Carpinetria CA, USA	1:200	Fierbere în target Retrieval high pH, DAKO
ER beta	Clone PP65/10	nucleii celulelor epiteliale în receptorii de estrogeni β	DAKO, Carpinetria CA, USA	1:10	Fierbere în target Retrieval S 1700
PGR	Clone 16	nucleii celulelor epiteliale glandulare şi stromale	Novocastra Leica-microsystems. com	1:100	Fierbere în tampon cittrat pH 6
Ki 67	Ac monoclonal 410-5M	Trusă de lucru NovoLink Min Polymer Delection System (50 tests)			
P 53	Ac monoclonal 195-5M				

REZULTATE

Diagnosticul histopatologic curent al celor 20 de paciente evidenţiază tendinţa la proliferare a endometrului ceea ce a determinat selectarea lor pentru IHC (tab. II)

Rezultatele imunohistochimice au relevat reacţie pozitivă la receptorii de estrogeni α şi β - dar mai intensă la β – în nucleii celulelor epiteliale glandulare atât în polipii adenomatoşi endometriali şi hiperplazie (fig. 1), cât şi în adenocarcinoamele endometrioide diferenţiate (fig. 2).

TABELUL II

Diagnosticul histopatologic al celor 20 de paciente

Nr crt.	Diagnostic histopatologic	Nr paciente
1	Polipi adenomatoşi endometriali	4
2	Hiperplazie endometrială simplă	6
3	Hiperplazie endometrială complexă	3
4	Hiperplazie endometrială complexă atipică	1
5	Adenocarcinom endometrioid diferenţiat	5
6	Adenocarcinom mixt endometrioid diferenţiat şi carcinom cu celule clare solid	1

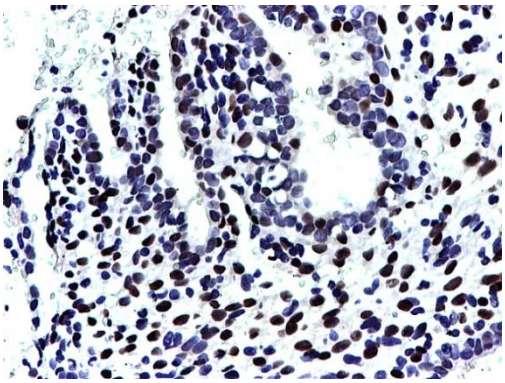

Fig. 1. Hiperplazie endometrială simplă. Reacţie intens pozitivă în nucleii celulelor epiteliale şi al unor celule stromale. (IHC - receptor de progesteron, ob. x20)

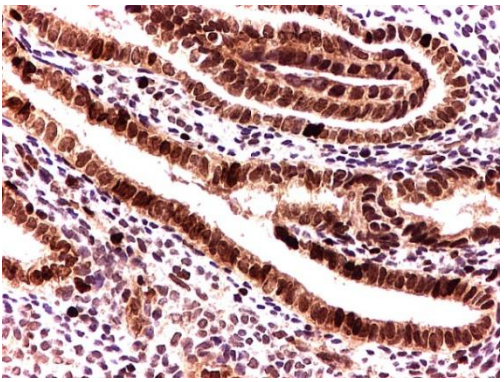

Fig. 2. Hiperplazie endometrială complexă. Reacţie intens pozitivă în nucleii celulelor epiteliale (IHC-receptor beta-estrogeni, ob. x20)

În ariile de carcinom endometrial cu celule clare marcajul pentru receptori α şi β estrogeni a fost negativ. Receptorii pentru progesteron au fost intens pozitivi în nucleii celulelor epiteliale şi în celulele stromale (fig. 3) din polipi, hiperplazii şi adenocarcinoamele endometrioide şi negativ în ariile de carcinom cu celule clare (fig. 4).

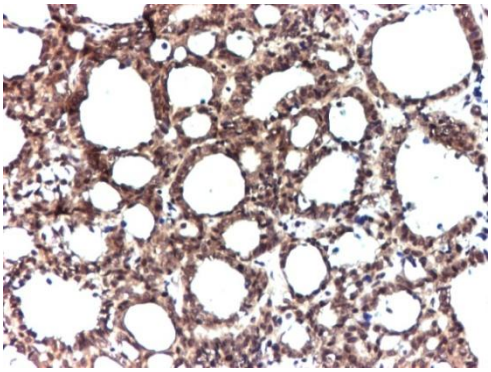

Fig. 3. Carcinom endometrioid diferenţiat. Marcaj intens pentru receptorii beta estrogeni din nucleii celulelor epiteliale. (ob. x10)

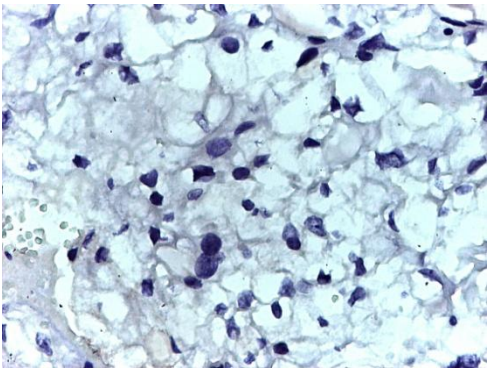

Fig. 4. Carcinom endometrial cu celule clare Receptor β estrogeni negativi. (ob. x20)

Marcajul pentru Ki-67 a fost slab în focar în polipi şi hiperplaziile simple, foarte intens şi continuu în toate tipurile de adenocarcinom (fig. 5).

În ceea ce priveşte proteinele genei mutante p 53, acestea au fost absente în polipii endometriali şi hiperplaziile complexe, moderat în nucleii adenocarcinoamelor endometrioide şi intens în carcinomul endometrial cu celule clare (fig. 6) (tab. III).

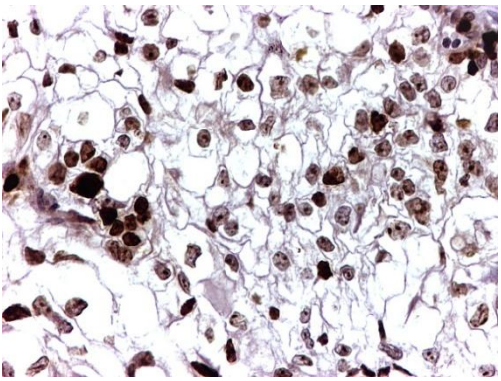

Fig. 5. Carcinom endometrial cu celule clare. Marcaj intens pozitiv pentru Ki 67 în nucleii celulelor tumorale. (ob. x20)

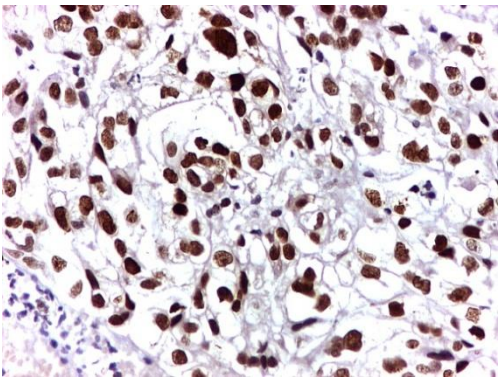

Fig. 6. Carcinom endometrial cu celule clare. Marcaj intens pentru p53. (ob. x20)

În ceea ce priveşte proteinele genei mutante p 53, acestea au fost absente în polipii endometriali şi hiperplaziile complexe, moderat în nucleii adenocarcinoamelor endometrioide şi intens în carcinomul endometrial cu celule clare (fig.6) (tab. III).

TABELUL III

Diagnostic imunohistochimic*

Nr. crt.	Tipul de leziune	Receptori α-estrogen	Receptori β-estrogen	Receptori progesteron	Ki-67	p53
1	Polipi adenomatoşi endometriali	+ +	+ + +	+ + +	+ în focar	N
2	Hiperplazie endometrială	+ +	+ + +	+ + +	+ în focar	N
3	Adenocarcinom endometrioid grad 1,2	+ +	+ + +	+ + +	+ +	N
4	Carcinom cu celule clare endometrial	N	N	N	+ + +	+ +

(*) N = negativ; intensitatea marcajului: +, ++, +++.

DISCUŢII ŞI CONCLUZII

Numeroase studii au arătat că utilizarea tamoxifenului ca adjuvant în terapia post-mastectomie pentru carcinom de glandă mamară creşte riscul apariţiei unor modificări histologice endometriale cu caracter proliferativ (în general benigne) până la leziuni premaligne şi maligne (2, 3). Tamoxifenul are un efect asupra endometrului când este în competiţie cu secreţia ovariană de estrogeni, dar concomitent are un efect paradoxal estrogenic în absenţa unei secreţii estrogenice ovariene (4).

Expresia receptorilor de estrogeni (ER) şi progesteron e moderată până la intensă în carcinoamele endometrioide, dar este absentă sau slab exprimată în carcinoamul cu celule clare (5, 6).

De asemenea, expresia ER şi PR e redusă în carcinoamele endometrioide slab diferenţiate (grad 3), ca şi în carcinoamele seroase şi cu celule clare (7).

În leziunile proliferative endometriale (polipi şi hiperplazie) s-a observat o tendinţă relativ redusă la marcajul cu Ki-67 şi negativă la p53. În adenocarcinomul endometrioid diferenţiat grad 1,2 se constată un marcaj moderat pentru Ki-67 şi p 53.

Un test IHC pentru p 53 permite recunoaşterea proteinei p 53 anormală, ce rezultă dintr-o mutaţie a genei, cu acumularea în nucleii celulelor tumorale, probabil printr-o degradare scăzută sau stabilizare.

Există expresia intensă a imunoreactivităţii p 53 în adenocarcinoamele endometrioide în paralel cu creşterea gradelor. Astfel, adenocarcinoamele de grad 3 se vor colora intens (8).

Carcinomul cu celule clare prezintă supraexpresia Ki-67 şi marcaj p 53 intens.

În general, studiul IHC a arătat că adenocarcinomul endometrioid, care apare în cursul terapiei cu tamoxifen se caracterizează printr-o expresie mai scăzută a receptorilor α estrogeni şi mai intensă a receptorilor de progesteron şi mai frecventă a receptorilor β estrogeni decât în tumorile endometriale spontane.

PPARs: STRUCTURE, MECHANISMS OF ACTION AND CONTROL.Note I (Abstract). PPARs (peroxisome proliferator activated receptors) are proteine receptors that act as transcription factors activated by ligands. There are three known isoforms of PPARs (α, β/δ, γ) with similar modulated structure, consisting of distinct regions with specific functions. PPARs activate transcription of their target genes by forming cytoplasmatic heterodimers (PPARs:RXR) with his partner RXR (retinoid X receptor), and once translocated into the nucleus bind to specific DNA sequence called PPRE (peroxisome proliferator response elements) and modulate the expression of genes. Each PPAR is differently expressed in various tissues. Modulatory function of PPARs is induced by natural or synthetic ligand binding. Additional activator proteins are recruited to form a complex that coordinates and regulates the expression of many genes.. Moreover, nuclear receptors' activity is also regulated by posttranslational changes. **Key words**: PPARs, STRUCTURE, LIGANDS, COREGLATORS, POSTTRANSLATIONAL CHANGES

PPARs: (peroxisome proliferator-activated receptors) sunt reprezentați de o familie de receptori nucleari (NR) proteici care acționează ca factori de transcripție activați de ligand (1, 2).

Nomenclatura, tipuri şi distribuția PPARs.

Subfamiliei de receptori nucleari PPARs aparțin 3 membri (izotipuri, izoforme) principali : PPARα (NR1C1= NR subfamilia 1, grupa C, numărul receptorului), PPAR β/δ (NR1C2) cunoscut şi sub alte denumiri – NUC-1 (nucleare abnormal-1) sau FAAR (fatty acid activated receptor) şi PPARγ (NR1C3) (3).

Aceste izoforme, codificate de gene specifice separate, etalează distribuție tisulară, funcții fiziologice şi profile farmacologice distincte care depind de genele țintă.

- PPAR α se exprimă preponderent în țesuturile cu catabolism activ al acizilor graşi : ficat, inimă, muşchi, țesut adipos, rinichi, precum şi în celulele endoteliale vasculare, VSMC (vascular smooth muscle cells), monocite/macrofage din peretele arterial (1, 4).
- PPAR β/δ este distribuit ubicuitar (5) în principal în creier, țesut adipos, piele.
- PPAR γ se exprimă în mai multe forme (γ1, γ2, γ3, γ4, γ5, γ7,)(6, 7) distribuite astfel :

- γ 1 se exprimă în toate țesuturile, incluzând inimă, muşchi, colon, rinichi, pan-

creas, splină ;

- γ 2 se exprimă în pricipal în țesutul adipos ;

- γ 3 se exprimă în macrofage, intestin gros, țesut adipos alb ;

- în macrofage au fost identificate tipurile de PPAR γ4, γ5, γ7 (γ6 nu a fost detectat) sugerând contribuția la funcția macrofagului (8).

În multe tipuri de celule se exprimă mai mult decât o izoformă.

Trăsăturile structurale ale PPARs şi mecanism de acțiune.

În ciuda diferențelor de localizare şi funcționale, PPARs prezintă aceeaşi structură generală (9). Ca şi alti receptori nucleari, au structură modulară cu mai multe domenii funcționale distincte (A/B, C, D, E)(domeniul F este absent din PPARs) (10), tipică membrilor superfamiliei de receptori nucleari (9,11) (Fig. 1):

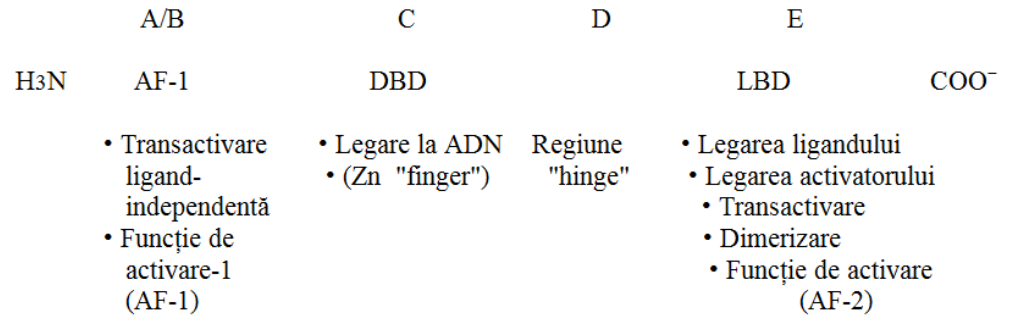

Fig. 1. Structura clasică a PPARs

Pentru fiecare din aceste domenii au fost stabilite funcțiile cheie (12).

● Domeniul A/B : regiune N-terminală, cu secvență foarte variabilă între diferite tipuri de receptori, este dinamică, lipsindu-i structura pliată în ciuda proprietății de activare a genei (13). Are funcție activatoare transcripțională independentă de ligand denumită AF-1 cu specificitate tisulară care leagă cofactorul. Activarea tisulară este foarte slabă, dar sinergică cu a AF-2 din domeniul E (LBD) (14).

● Domeniul C: DBD (DNA binding domain) este un domeniu înalt conservat, cu o structură caracteristică de meandru (helix-loop-helix) stabilizată de 2 atomi de Zn (Zn "finger") care asigură interacțiunea cu o secvență specifică **genomică** (tipar) numită PPRE (peroxisome proliferator response elements). În citozol PPARs formează cu pertenerul lui RXR (NR2B) (retinoid X receptor) heterodimerul PPARs:RXR care translocat în nucleu este recunoscut şi fixat pe secvența PPRE din ADN (15). Asocierea PPARs cu RXR apare independentă de legarea ligandului iar nu necesită întotdeauna legarea la ADN (16).

PPRE amplasat în protomerul genei țintă este constituit din repetarea unei secvențe scurte alcătuită din două unități hexamere – AGGTCA**N**AGGTCA (DR-1 şi DR-2 – direct repeat-1 şi direct repeat-2), spațiate de 1-2 nucleotide oarecare (**N**) (17).

● Domeniul D ("hinge", balama), nespecific, conectat la DBD asigură flexibilitatea între partea N-terminală şi C-terminală a moleculei, este implicat în legarea corepresorului (10).

● Domeniul E: LBD (ligand binding

domain) cu o structură moderat conservată în secvenţă, dar înalt conservată în structura tridimensională (18). LBD este o regiune complexă care conţine câteva activităţi bine integrate şi interdependente: un buzunar (cavitate) hidrofob (ă) de legare a liganzilor naturali sau sintetici, o interfaţă de dimerizare şi o interfaţă de transactivare ligand-dependentă (AF-2)(14).

Funcţiile PPARs sunt determinate de configuraţia precisă a domeniului care leagă ligandul (activatorul) indusă după legarea acestuia şi de un număr de proteine auxiliare denumite cofactori (corepresori şi coactivatori) a căror prezenţă potenţează transcripţia sau inhibă funcţia receptorului respectiv (19) şi mediază contactul cu heterodimerul PPAR:RXR, cromatină şi "maşinăria" transcripţională (20, 21, 22).

Acţiuni non-genomice

PPARs prezintă unele mecanisme de acţiune, mai puţin aşteptate, la nivel non-genomic (independente de ADN). Aceşti receptori pot media efecte represive indirecte denumite transrepresie. Transrepresia poate fi determinată de inhibarea legării factorilor de transcripţie la ADN prin interacţiune proteină-proteină (16) sau prin sechestrarea cofactorilor necesari activităţii lor (23, 16).

Mecanisme de reglare transcripţională

Controlul transcripţional este un proces care se desfăşoară în mai multe etape, reflectat, de specificitatea şi disponibilitatea ligandului, recrutarea cofactorilor, modificarea posttranslaţională care afectează stabilitatea şi potenţa receptorului.

Liganzii sunt compuşi naturali sau sintetici care induc o conformaţie distinctă a receptorului. Există o oarecare specificitate între liganzi şi subtipurile de PPARs determinată de structura şi aminoacizii din buzunarul de legare a izotipurilor de receptori (24).

În categoria liganzilor naturali endogeni pentru cele trei izoforme de PPARs sunt incluşi: PPARs α: acizi graşi şi compuşi derivaşi de la acizi graşi, eicosanoide naturale derivate de la acid arahidonic pe calea lipoxigenazei ca leucotriena B4 şi fosfolipide xidate din lipoproteine oxidate (25); PPARγ: acizi graşi şi compuşi derivaţi de la acizi graşi. De asemenea este receptor pentru metaboliţi eicosanoidici formaţi pe calea ciclooxigenazei precum prostaglandine (PGJ2, PGH1, PGH2) (26) şi pe calea lipoxogenazei; PPARα, -γ, -β/δ sunt receptori pentru acizi graşi nesaturaţi. În plus de exprimarea preferenţială în anumite ţesuturi, PPARs sunt senzori capabili de adaptare a exprimării genei la diferiţi stimuli: stres şi ritmul circadian (27), post (28), frig (29). De asemenea, exprimarea PPAR este afectată de insulină şi corticosteroizi (30), diferite citochine (31).

Liganzii sintetici (agoniştii sintetici) sunt reprezentaţi de hipolipidemiante, antiinflamatoare, compuşi insulino-sensibilizatori, antidiabetice. Agoniştii sintetici ai PPARs sunt folosiţi în tratamentul unor afecţiuni metabolice precum diabetul de tip 2 şi dislipidemie. Glitazonele antidiabetice (rosiglitazone, pioglitazone), sensibilizatori de insulină sunt liganzi cu mare afinitate pentru PPARγ (32). Fibraţii, droguri hipolipidemice, sunt liganzi PPARα (25). Beneficiile clinice incontestabile ale agoniştilor PPARγ în tratamentul diabetului de tip 2 sunt dublate de efecte colaterale precum creşterea în greutate şi edem, fapt ce a stimulat interesul pentru obţinerea de modulatori care să reţină eficacitatea de sensibilizatori la insulină dar să minimalizeze efectele adverse (33).

Recent s-au sintetizat o serie de agonişti PPAR cu mare afinitate subtip-specifici

(34). Diversitatea liganzilor găzduiţi în buzunarul de legare a ligandului precum şi varietatea modificărilor induse de ligand, reflectă şi diversitatea funcţiilor în care PPARs sunt implicaţi.

Reglarea PPARs de cofactori

În afară de configuraţia precisă a domeniului de legare a ligandului (activatorului) indusă după legarea acestuia, funcţiile PPARs sunt influenţate şi de un număr de cofactori (coactivatori şi corepresori) a căror prezenţă poate stimula sau inhiba funcţia receptorului respectiv (8, 20) prin legarea factorilor de transcripţie la "maşinăria" transcripţională şi modificarea specifică a structurii cromatinei (21). Cofactorii (coreglatorii) sunt proteine funcţionale care asigură controlul transcripţional PPAR-mediat al genelor ţintă (12, 20). In cursul ultimilor 15 ani au fost identificaţi mai mult de 300 de cofactori (corepresori şi coactivatori) care interacţionează cu receptorii nucleari şi le mediază activitatea transcripţională (35), dar funcţia reglatorie fiziologică a multora dintre aceste molecule rămâne de explorat.

Corepresori**.** În absenţa ligandului, heterodimerul receptorului nuclear este asociat cu corepresorul (i), proteină (e) care inhibă proprietatea transactivatoare. În această stare inactivată, în unele dar nu în toate tipurile de celule, PPARS pot fi localizaţi mai curând în citozol decât în nucleu . Heterodimerul formează complexe cu corepresori precum NCoR (nuclear receptor corepressor), RIP 140 (receptor interacting protein 140) sau SMRT (silencing mediator of retinoid and thyroid receptors) ce recrutează histon deacetilaza, determinând represia transcripţiei (12, 36, 37). Este posibil să prezinte un rol şi interacţiunile cu "maşinăria" bazală transcripţională (38). Altă clasă de corepresori ligand-dependenţi sunt recrutaţi prin intermediul unor secvenţe scurte L/VXX-I/V-I (L=leucina, V=valina, I=izoleucina, X=un aminoacid oarecare) sau LXXXI/LXXXI/L (19) care represează activitatea receptorului prin competiţie cu coactivatori. Deşi corepresorii prezintă o mare diversitate structurală, mecanisme de represie şi funcţii fiziologice, ei recrutează efectori din aval precum histon deacetilaza pentru a-şi exercita efectele represive (19).

Coactivatori**.** Transactivarea este indusă prin mecanisme ligand-dependente şi ligand-independente, acestea din urmă mai puţin înţelese. Recent s-au identificat proteine NCoEx (nuclear corepressor exchange factors) (39), care asociate cu receptorul nuclear favorizează schimbul corepresor cu coactivator, schimb ce promovează tranziţia de la starea represivă la cea activă. Legarea ligandului induce o modificare conformaţională a heterodimerului care exclude corepresorii din complex şi expune locuri de legare ale coactivatorului nedisponibile în absenţa ligandului. Coactivatorii conţin 3 secvenţe de LXXLL care mediază recunoaşterea şi legarea la AF2 (40), dar nu toţi coactivatorii utilizează această secvenţă pentru interacţiunea cu diferiţi receptori nucleari.

PPARs interacţionează cu un mare număr de complexe proteice coactivator cu multiple subunităţi cu funcţii diferite: unele prezintă activitate histon acetiltransferazică sau metiltransferazică intrinseci, altele facilitează remodelarea cromatinei ATP-dependentă sau folosesc ca punţi de legare cu "maşinăria" transcripţională. Perturbarea exprimării coactivatorilor poate afecta funcţia PPARs (20).

Proteinele implicate în modificarea cromatinei sunt complexele SWI/SNF (switch/ sucrose non-fermeting) (16) sau factori

care modifică covalent histonele prin acetilare, metilare,fosforilare, ubiquitinare, modificări ce pot apare într-un mare număr de combinaţii, adesea în mod interdependent (41). În consecinţă, recrutarea coactivatorilor duce la răspunsuri biologice distincte (42).

Reglarea PPARs prin modificare posttranslaţională

În plus de liganzi şi cofactori, activitatea PPARs este reglată prin modificări posttranslaţionale care pot contribui la afectarea activităţii acestor receptori nucleari.

Fosforilarea. La nivel molecular, efectele fosforilării PPARs-mediate prin diferite mecanisme, includ modificarea afinităţii pentru liganzi (43), RXR (44,) şi cofactori (45) care adesea se datorează modificării conformaţionale a întregului receptor (46). PPARα şi PPARγ sunt fosfoproteine, a căror grad de fosforilare afectează activitatea transcripţională (47).

Ubiquitinarea. Ubiquitina este o proteină mică care se leagă covalent la proteine expunându-le la degradare mediată de proteasomi (48). Ubiquitinarea şi degradarea PPARs proteasomi-mediată sunt legate de activitatea transcripţională a receptorului nuclear prin reglarea nivelului celular al receptorului. Spre exemplu, tiazolidindionele induc ubiquitinarea receptorului PPARγ şi ulterior degradarea de proteasomi (49), fibraţii inhibă ubiquitinarea şi cresc timpul de înjumătăţire a proteinei PPARα (49).

Sumoilarea. SUMO (**s**mall **u**biquitin-like **mo**difiers) alcătuit dintr-o familie de proteine omologe cu ubiquitina reglează diferite mecanisme celulare, inclusiv represia transcripţiei (50). Represia transcripţională de către SUMO este în general mediată de recrutarea corepresorilor şi a histon deacetilazei (51).

Nitrarea resturilor tirozil din PPARγ inhibă translocarea acestuia din citozol în nucleu (52) reducându-i capacitatea de a influenţa transcripţia genei.

Izoformele PPARs codificate de gene separate care se deosebesc prin distribuţie, selectivitate şi sensibilitate la liganzi şi recrutarea de proteine distincte (corepresori şi coactivatori) contribuie la reglarea diferitelor seturi de gene specifice (53) implicate în variate funcţii celulare metabolice şi non-metabolice: metabolism energetic (lipidic, glucidic, proteic), termogeneză, diferenţiere celulară, precum şi în exprimarea genelor cheie în diferite stări de boală (16, 54, 55, 56).

BROMINATION-A VERSATILE TOOL FOR DRUGS OPTIMIZATION (Abstract): Scientific literature presents many naturally occurring brominated substances exhibiting different biological activities. Most natural brominated derivatives have been isolated from the marine biosphere, being metabolites of algae, sponges and corals. These molecules became structural models for obtaining synthetic derivatives with superior bioactive potential. The present paper is an analysis of previously published studies on the influence of insertion of bromine atoms in different molecules on their bioactivity. In general, the results confirmed the positive effect of bromination on the bioactive potential of substances. The mechanisms explaining these results are still insufficiently elucidated, several possibilities being mentioned: increased lipophilicity and permeability through biological membranes, increased half-life or the possibility of intermolecular bond formation (attractive interactions) between the electrophilic region of the molecule containing bromine atoms and various nucleophilic active sites of biomolecules. In conclusion, bromination may be a way to increase the potency of therapeutic agents and research in the field of molecular design of brominated compounds will certainly continue. **Keywords**: BROMINE DERIVATIVES, BIOLOGICAL ACTIONS, DRUG DESIGN.

There is constant preoccupation for discovering new therapeutic agents, both naturally-occurring and synthetic compounds. The substances isolated from the natural environment can become structural models for the synthesis of new derivatives, this research field being an area of great interest. The present review focuses on the importance of bromine-containing compounds and is divided into two main sections: naturally occurring bromo-derivatives and synthetic bromo-derivatives with important biological activities. Many brominated derivatives are mentioned and characterized in the scientific literature. They were isolated from natural sources or chemically obtained and exhibited many biological activities. Nowadays, computational tools have been intensively employed in the field medicinal chemistry, QSAR (Quantitative Structure-Activity Relationship) modelling being the most popular. There is evidence linking the presence of halogen atoms in molecules with a positive influence on various biological activities, halogenation becoming an important tool for drug optimization (1).

Naturally occurring bromo-derivatives

In the late nineteenth century, Drechsel, cited by Murphy (1), was the first to report

the isolation of a halogen-containing natural product - diiodotyrosine - from the coral *Gorgonia cavolii*. In 1968, around 50 examples of halogenated natural products were reported. The discoveries in this area have increased exponentially over the last decades, changing the perception that organohalogens found in the environment were mostly of anthropogenic origin. Most of the halogen-containing natural substances were isolated from the marine biosphere (2, 3). The marine biosphere is a medium rich in halogenated compounds, about 5000 being identified so far. Marine organisms (algae, sponges, corals) produce a wide range of bioactive metabolites in response to ecological pressure (4), 45 percent of them being bromo-metabolites due to the high concentration of bromine in sea water (1). Excellent reviews on marine natural compounds were recently published (2, 4, 5, 6).

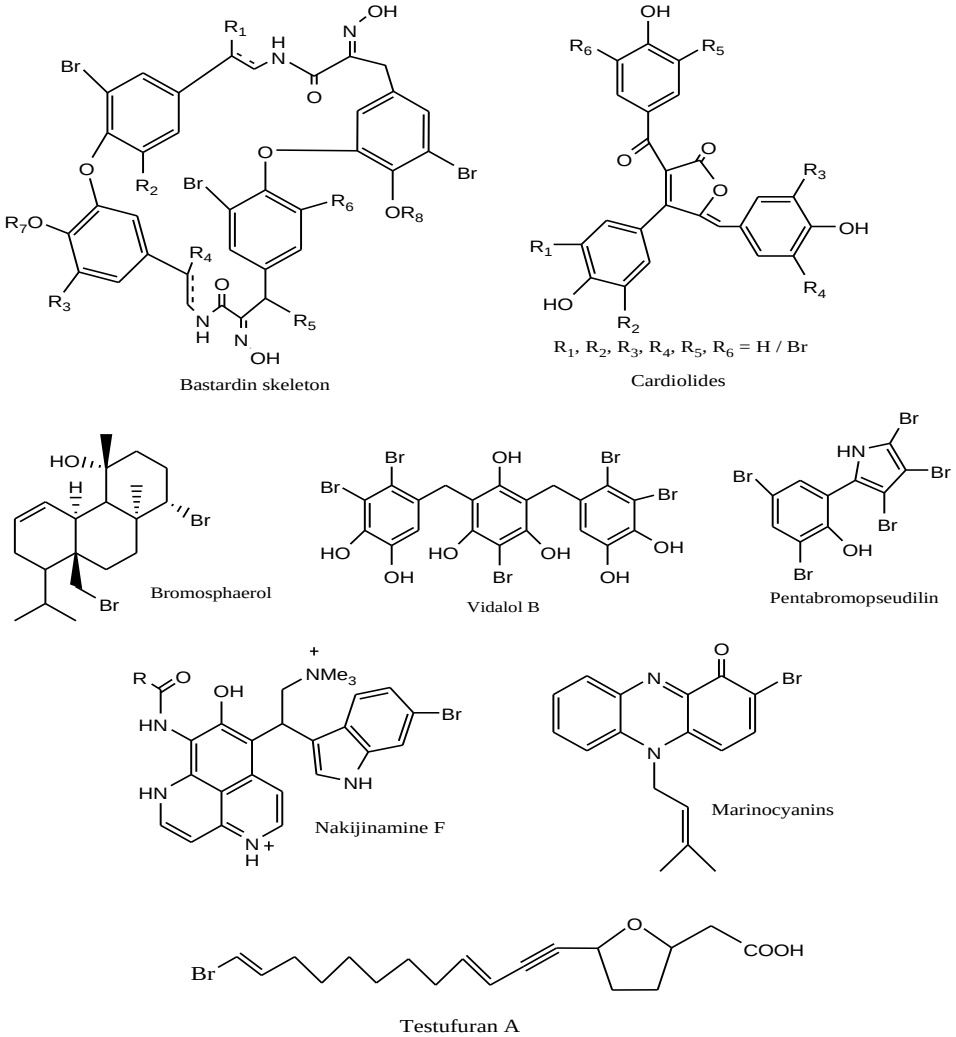

Fig. 1. Representative natural brominated compounds

Chemically, the bromo-metabolites of marine flora include phenols (vidalol A and B), tyrosine derivatives (bastadins), furanones (cadiolides), pyrrole derivatives (pentabromopseudilin), diterpenes (bromosphaerols), alkaloids (keramadine), phenazinone derivatives (marinocyanins), imidazole derivatives (massadine), indole derivatives (nakijinamines), polyunsaturated lipids (xestonarienes), carboxylic acids (testufuran A), glycopeptides (theonellamide G), macrolides (callyspongiolide), brominated monocarbocyclic oxylipins (bromovulone). In figure 1 are presented some of the most important bromine-containing natural molecules. The purpose of the current review is not an exhaustive presentation of the brominated compounds isolated from natural sources, but to stress upon the diversity and biological importance of these compounds.

Bromo-compounds found in the natural environment exhibited a wide range of biological activities: antibacterial, antifungal, antiparasitic, antiviral, antitumor, antioxidant, anti-inflammatory and enzymatic activity (protein kinase inhibition, acetylcholinesterase inhibition) (2, 7, 8, 9, 10, 11). Several natural brominated substances were also active inhibitors of bacterial biofilm formation (bromoageliferin, brominated furanones, bromopyrrole alkaloids) (12).

Synthetic bromo-derivatives with important biological activities

The large number of natural brominated metabolites with many applications in the pharmaceutical field encouraged the research in synthesis and biological evaluation of bromine-containing compounds. There are many studies proving that adding halogen atoms to a pharmacophore can be beneficial for its bioactivity, halogen insertion being considered a traditional tool in drug optimization. In recent years, there is an ever-growing interest in halogenated drugs.

The halogenation degree also influences the lipophilicity and cell membrane solubility of the compounds. Surface activity and permeability coefficient are other parameters used to show that halogenation of drugs improves membrane binding, permeation and diffusion in general. *In vivo* half-life of the substance is also influenced (13, 14). The usefulness of a drug depends on its ability to reach appropriate receptors in the target tissue and remain metabolically stable to produce the desired effect. In this regard, halogenated enkephalin analogues involved in antinociceptive processes were synthesized to improve the stability and bioavailability of the compounds. The study was focused on the investigation of the effect of halogenation on stability, lipophilicity and *in vitro* blood-brain barrier permeability of the novel enkephalin analogues. Bromine and chlorine additions significantly enhanced *in vitro* blood-brain barrier permeability, providing evidence for improved delivery to the central nervous system (14).

Besides the steric and lipophilic contributions of halogens, organobromines also have the capacity to form halogen bonds (non-covalent interactions) with different biomolecules, improving drug-target binding affinity. Studies confirmed that halogen bonding interactions are responsible for different conformations of molecules in the active site. Halogen bonds also affect binding between drugs and transport proteins, playing an import role in distribution. In

addition, halogen bonds were found to influence metabolic and detoxification processes (15, 16).

Several biological actions were distinguished for bromine-containing compounds: antimicrobial, antioxidant, antitumor, antiplasmodial, gastroprotective.

Antimicrobial activity. Infectious diseases currently represent a great concern for the medical world. The increase in the occurrence of different infections overlaps with the overprescribing phenomenon that has made antibiotics less effective and microbes resistant to one or more antimicrobial agents. In this context, there is a constant search for new antimicrobial agents. There are many examples of compounds with bromine atoms that exhibited a good antimicrobial potential. QSAR studies analyze the comparative biological effects of different substances depending on the nature of the substituents present in their molecules and there is substantial data supporting the hypothesis that the presence of bromine substituents has a positive influence on the biological activity.

Many natural derivatives present antimicrobial activity. The fimbrolides isolated from *Delisea pulchra* inhibit the quorum sensing (QS), a regulatory communication system between bacteria of several bacterial species and are a good starting point for chemical manipulation. Steenackers *et al*. demonstrated the importance of bromo-substituents on fimbrolides for the bacterial QS inhibitory activity, the introduction of a bromine atom drastically enhancing the activity of the furanones (17). Other brominated heterocycles (furanones, pyrrolones and pyridazinones) were synthesized as antibacterial agents, with anti-quorum sensing activity (18). The dibromomethylene group was found to be important for the anti-QS activity of some pyridazinones, disrupting bacterial cell-to-cell communication and affecting biofilm formation (19).

Based on the natural model provided by bromophenolic dimers isolated from red algae of *Rhodomelaceae* family, several brominated resorcinol dimers with antibacterial activity were synthesized. The presence of bromine atoms on the phenol ring was important for the antimicrobial activity (20).

Several halogenated derivatives of 3-methyleneflavanone were synthesized and the substitution of one ring with chlorine and bromine atoms was found to enhance antibacterial activity, the chloro- and bromo-analogues being approximately twice as effective as their parent compounds against *S. aureus*, and four times more active against *Enterococcus faecalis* (21).

The bromination of 2-(2′-hydroxybenzoyl) pyrrole led to a series of derivatives, related to monodeoxypyoluteorin, whose antimicrobial activity against *Staphylococcus aureus* increased with the degree of halogenation. The most active member of the series was the pentabromo-derivative, exhibiting a MIC (minimum inhibitory concentration) against *S. aureus* ATCC 25923 of 0.005 μg/mL and promising activity against preformed *S. epidermidis* and *S. aureus* biofilms (22).

New compounds with Bromo pyrrole and 1,3,4-oxadiazole moieties were synthesized and their antimicrobial potential was determined. The hybrids showed promising antibacterial activity against *S. aureus*, *E. coli* and *Mycobacterium tuberculosis* and antifungal potential (23). Of the nitrovinylfurans, 2-bromo-5-(2-bromo-2-nitrovinyl)

furan was remarked for its broad-spectrum antibacterial and antifungal properties. The bromo(nitro)methyl unit was found to be essential for the antibacterial activity and MurA enzyme inhibition (24). It was observed that 5- and 6-bromo substituted compounds possessing a central benzimidazole ring showed a good antimycobacterial activity, probably due to the higher hydrophobicity of bromine, making the molecule more lipophilic and more cell-permeable. 5- and 6-bromo-1-((phenyl) sulfonyl)-2-((4-nitrophenoxy) methyl)-1H-benzimidazoles are potential antitubercular agents (25).

The antimicrobial activity of three new ferrocene derivatives containing 2,3-dihydroquinolin-4(1H)-ones was tested. They showed a very strong and unselective activity against all tested microorganisms (Gram-positive and Gram-negative bacteria and *Candida albicans*). The bromine-containing compound, the most active of all three, had MIC values lower than tetracycline for all bacterial strains (26).

Four N-cinnamoyl amino acid amides were brominated and the antimicrobial activity of the resulting α, β-dibromohydrocinnamoyl amino acid amides against *Escherichia coli*, *Staphylococcus aureus* and *Candida albicans* was tested. Two of the compounds were active against *S. aureus*, being good candidates for further studies, one of them emerged as a highly active agent, displaying a strong inhibition potential against *E. coli* as well (27). There are also reports that the bromination of the double bond of cinnamic acid and its derivatives caused remarkable enhancement of the antimicrobial activity (28, 29).

Staneva *et al*. described the peripheral modification of a second-generation polypropylene amine dendrimer with eight 4-bromo-1,8-naphthalimide units and its copper and zinc complexes, revealing promising antimicrobial activities against some pathogenic Gram-positive and Gram-negative bacteria and *Candida lipolytica* yeasts (30).

Salicylanilides presented significant *in vitro* antimicrobial and antifungal activities. The influence of different substituents on the salicylanilide molecule on the antimycobacterial and antimicrobial activities was highlighted. The presence of chlorine and bromine atoms on the salicylic ring had a positive impact on bacterial growth inhibition. Bromine derivatives were more active than their chlorine analogues, regardless of the position of the halogen, most likely because of the higher calculated ClogP values. 5-bromo-2-hydroxy-N-(4-(trifluoromethyl) phenyl)-benzamide and 5-chloro-2-hydroxy-N-(4-(trifluoromethyl) phenyl)-benzamide were the most active salicylanilides (31).

Eight brominated 2'(4')-nitro-3-hydroxydiphenyl ethers were analyzed in terms of their antimicrobial potential and the compounds with more halogen atoms had a higher antibacterial activity than those less halogenated (32).

Antioxidant potential. Antioxidants may be of great benefit in improving the quality of life by preventing or postponing the onset of degenerative diseases, counteracting the negative effects of excess free radicals. Several research groups have proved that halogens are important for cellular antioxidant activity.

Barettin (isolated from the marine sponge *Geodia barretti*) is a molecule with a polar arginine and a non-polar brominated tryptophan end, presenting a strong

antioxidant activity, while its debrominated synthetic analogue did not display the same activity, indicating that bromine is important for the antioxidant potential (33). Similarly, the bromination of flavonoids gave derivatives with a higher free radical scavenging activity and higher lipophilicity than the parent compounds. Brominated flavonoids can diffuse easily through membranes, increasing the intracellular concentration of the compounds (34).

Another study analyzed the antioxidant properties of some phenolic Schiff bases and the impact of different substituents on the antioxidant activity. The conclusion of the study was that bromine substitution may slightly enhance the antioxidant activity (35). The results of a research concerning the antioxidant activity of a series of quinazolin-4-(3H)-ones showed that brominated compounds exhibited a better activity than unsubstituted ones. 6,8-dibromo-2-phenyl-3-(4-phenylthiazol-2-yl) -quinazolin-4(3H)-one exhibited the highest scavenger activity among the tested compounds (36). The evaluation of the antioxidant activity of some 1,2,4-triazole derivatives revealed that the insertion of a halogen atom (chlorine or bromine) had a positive impact on the antioxidant potential of the compounds (37, 38).

Although most studies indicate a positive influence of bromine atoms in the molecule, there are also opposite results in literature. For example, a series of chalcone fatty acid esters were synthesized and their antioxidant potential was evaluated. The results indicated that the addition of bromine to the double bond in the molecule caused the antioxidant activity to decrease (39). Another research team evaluated the antioxidant activity of some 3,5-disubstituted-2-pyrazolines. They concluded that the presence of halogens as substituents caused a reduced antioxidant activity (40). In another paper, the antioxidant and radical scavenging effects of some bromophenols were investigated, the activity exhibited by phenols with bromine and without bromine atoms being similar (41).

Anti-tumor activity. Cancer is responsible for a large percentage of all deaths worldwide and the percentage is still increasing. Therefore, there is a constant need for new compounds that can serve as leads for new anticancer drugs. New antitumor therapies point towards new compounds that demonstrate selective anticancer actions, exhibiting a cytotoxic effect on malignant cells, without damaging normal cells. The synthesis of brominated derivatives is considered a common way to gain cellular potency of anti-cancer agents, several bromine-containing compounds with cytotoxic potential being reported in literature. Pipobroman is an anti-cancer drug with bromine atoms in the molecule that probably acts as an alkylating agent.

Paclitaxel is an antitumor agent approved by the Food and Drug Administration for the treatment of several cancer forms. Nano-formulations of paclitaxel have been investigated for safer and more effective chemotherapy. Lipophilic paclitaxel conjugates bearing carbon chains at the 2′-position have the advantage of an increased stability. The incorporation of a bromine atom in the paclitaxel conjugates was also evaluated, the bromoacyl derivatives being 50 to 250-fold more cytotoxic than the molecules without Br in the human MCF-7 breast carcinoma cell line, indicat-

ing Br-induced hydrolysis. Peng *et al*. studied the 2′-(2-bromohexadecanoyl)-paclitaxel conjugate (Br-C16-PX) incorporated into lipid-based nanoparticles for the treatment of non-small cell lung cancer. The Br-C16-PX nanoparticles had a superior therapeutic efficacy and an improved pharmacokinetic profile compared to paclitaxel in the orthotopic xenograft model, the bromine group on the fatty acid chain enabling faster hydrolysis to release the active substance (42).

Noscapine, a microtubule-interfering agent, can arrest mitosis, to induce apoptosis and has a potent antitumor activity. Two brominated derivatives of noscapine, 5-bromonoscapine ((S)-3-((R)-9-bromo-4-methoxy-6-methyl-5,6,7,8-tetrahydro (1),(3) dioxolo(4,5-g)isoquinolin-5-yl)-6,7-dimethoxyiso-benzofuran-1(3H)-one) and reduced 5-bromonoscapine ((R)-9-bromo-5-((S)-4,5-dimethoxy-1,3-dihydroisobenzofuran-1-yl)-4-methoxy-6-methyl-5,6,7,8-tetra-hydro-(1),(3)di-oxolo-(4,5-g) isoquinoline), exhibited higher tubulin binding activity than noscapine and were able to arrest cell cycle progression at mitosis at concentrations much lower than noscapine. 5-Br-noscapine and reduced 5-Br-noscapine were active in inhibiting the proliferation of various human cancer cells, including those that were resistant to paclitaxel and epothilone (43). 9'-bromonoscapine is known as EM011 and it was introduced in clinical trials. The efficacy of EM011 was also assessed in CNS malignancies - low grade gliomas (a heterogeneous group of tumors, representing the most common form of neoplasms in the central nervous system among children). The results of the study indicated that EM011 decreased both tumor-cell proliferation and invasion indices, making it an appealing molecule for the treatment of pediatric low-grade gliomas (44). A third generation of di-substituted bromo analogues of noscapine was also synthesized, the novel di-substituted noscapinoids showing significant antiproliferative activity (45). N-(3-bromobenzyl)-noscapine, a third-generation noscapine analog, was slightly more potent than the first-generation clinical candidate EM011. The efficacy of noscapine and its analogs has been enhanced through nanoscale-based drug delivery systems (46).

Psammaplin A is also a natural bromine-containing cytotoxic compound. Hybrid agents are compounds designed to inhibit simultaneously multiple cellular targets relevant to tumor growth and survival. Cincinelli R. and her team designed a camptothecin-psammaplin hybrid with enhanced anticancer potential, targeting both topoisomerase I and HDAC enzymes (47).

Aroylhydrazones obtained by condensation between salicylaldehyde and different hydrazides possess diverse pharmacological activities, including anticancer. The cytotoxic effects of 5-bromosalicylaldehyde-4-hydroxybenzoylhydrazone and 5-bromosalicylaldehyde isonicotinoyl hydrazone were comparable to that of Cisplatin, the inclusion of a bromine atom greatly increasing the activity of the compounds (48).

Many synthetic heterocyclic compounds presented antitumor activity. Zhang *et al*. tested the ability of a series of synthetic brominated chalcone derivatives to inhibit the growth of cancer cell lines. Some compounds exhibited antiproliferative activity at lower concentrations than 5- fluorouracil, used as

the positive control. One of the compounds, H72, exhibited selective cytotoxicity against gastric cancer cells versus normal human gastric epithelial cells (49). The cytotoxicity of 5-bromo-6-(4-chlorophenyl)-2-propyl-imidazo (2,1-b) (1,3,4) thiadiazol was evaluated and compared to the standard antitumor drug Bleomycin. The results indicated relatively close cytotoxicity index values with the standard and lower cytotoxicity towards normal cells compared to Bleomycin, which represents an important advantage (50).

4,5,6,7-tetrabromo-1H-1,2,3-benzotriazole, 4,5,6,7-tetrabromo-1H-benzimidazole and 4,5,6,7-tetrabromo-1H-benzimidazole-2-N,N-dimethylamine derivatives are examples of brominated compounds with protein kinase inhibitory activity; they are specific inhibitors of casein kinase 2. It is an established fact that abnormal phosphorylation of proteins mediated by kinases may lead to cancer and, in consequence, the inhibition of protein kinases is a potential target in cancer treatment (51). The structure activity relationship analysis performed for new 3,6-disubstituted-1,2,4,5-tetrazine derivatives with antitumor activity revealed that the insertion of a bromine atom in the molecule significantly increased the cytotoxicity (52).

A few 6-bromine derivatives of 7-anilino-1-arylisoquinoline-quinone presented an antiproliferative effect against some cancer cell lines. The conclusion of the study was that the insertion of bromine atoms in the 6-position of the quinone ring of the isoquinoline-quinone scaffolds is an important factor for the antiproliferative activity (53). The influence of bromine substitution on the cytotoxic activity of some isoquinolinequinone-amino acid derivatives also depended greatly on the insertion position. One brominated analogue showed potent and selective cytotoxic activity on lung and bladder cancer cells, appearing as a new lead compound in the aminoisoquinoline-quinone series (54).

Antiplasmodial activity. Malaria is the most prevalent insect-borne parasitic disease, caused by protozoa belonging to the genus *Plasmodium*, a large percentage of the world population being at risk, mainly in the poorest countries. Malaria therapy is affected by the appearance of chloroquine-resistant *Plasmodium* strains, making the discovery of new drugs a priority. A series of halogenated 4-quinolones was synthesized and their activity against *Plasmodium falciparum* was investigated. The introduction of a bromine atom on the quinolone skeleton caused an increase in the antiplasmodial activity (55). The antimalarial potential of a series of 1,2-substituted-4(1*H*)-quinolones was also investigated. The presence of an aliphatic group containing a bromine atom at C-2 enhanced the *Plasmodium falciparum in vitro* inhibition. On the other hand, introduction of a phenyl group in the aliphatic side chain at C-2 dramatically increased the antimalarial potency; the compound with a phenyl group and a bromine atom at the end of the aliphatic side chain appeared to be the most potent antimalarial agent (56).

Ellipticine is an alkaloid first extracted from *Ochrosia elliptica* and *Rauvolfia sandwicensis*. Ellipticine and its analogues exhibit antimalarial potential. Ring brominated and nitrated ellipticine derivatives also presented good *in vitro* inhibition of *Plasmodium falciparum* (57). Other alkaloids with antiplasmodial activity are cryptolepine and neocryptolepine, isolated from *Cryptolepis sanguinolenta*. Cryptolepine derivatives with a halo-

gen attached to the quinoline ring and a halogen or a nitro group on the indole ring presented enhanced antiplasmodial activity. 2,7-dibromocryptolepine was very potent and possessed encouraging *in vivo* activity in mice infected with *P.berghei* (58). Neocryptolepine presented lower cytotoxic potential than cryptolepine, so it can become a starting point for the development of new antimalarial agents. 2-bromo- and 3-bromo-neocryptolepine proved to be more active than neocryptolepine itself, but not as active as cryptolepine. 2-bromoneocryptolepine showed selectivity towards the *Plasmodium* parasite, justifying its position as the most promising lead now in the series of the neocryptolepine derivatives. Furthermore, 2-bromoneocryptolepine showed a low affinity for DNA and no inhibition of human topoisomerase II, revealing no obvious cytotoxicity (59).

Anti-inflammatory. Based on the structural resemblance of noscapine to colchicine, a tubulin-binding anti-inflammatory drug, noscapine and its semi-synthetic brominated analogues were examined for *in vitro* anti-inflammatory activity. Brominated noscapine analogues were found to inhibit cytokine and chemokine release from macrophage cell lines but did not affect cell viability. Brominated noscapine analogues displayed a significantly higher anti-inflammatory activity compared to the parent drug - noscapine (60).

Chrysin is a naturally occurring flavone with an anti-inflammatory effect. Some 6,8-dihalogenated chrysin derivatives were synthesized and their anti-inflammatory activities were evaluated in comparison to the initial compound. Although the dihalogenation of chrysin increased the *in vitro* anti-inflammatory activity, no significant difference between chrysin and dibromochrysin or diiodochrysin was recorded in *in vivo* carrageenan-induced inflammatory activity test. One possible explanation of the phenomenon could be the low permeability through the skin to the target inflammation sites of the dihalogenated chrysin derivatives, due to their large molecular structures (61).

The anti-inflammatory potential of several halogenated isatin derivatives was tested, the activity varying according to type of halogen and the position of the substituent. The investigated parameters were the inhibition of TNFα, NO and PGE_2. The results suggested that bromine C5- and C6-substituted isatin analogues displayed an increased anti-inflammatory activity (62).

Gastroprotection. Bromine substituted Schiff base - copper and zinc complexes showed amazing gastroprotective activity. The presence of bromine atoms coordinated to the zinc metal ion seemed a possible active site for the complex due to the electron donating properties of the halogens by resonance, making the lone pair of electrons more available to a plausible electron transfer (63, 64).

CONCLUSIONS

The field of bromine-containing substances constitutes a research area of great interest due to the importance of these derivatives as bioactive agents. Many natural or synthetic compounds have been studied so far and very interesting biological properties have been revealed. The insertion of bromine atoms in the molecule is usually associated with the enhancement of the bioactive potential, bromination becoming an important tool for the design of new drug candidates.

3D BIOPRINTED CARTILAGE: A NEW ERA IN BIOENGINEERING

The advent of 3D bioprinting has revolutionized the area of tissue bioengineering and it is becoming a linchpin in reconstructive surgery as surgeons are using bioengineering techniques to push standard flaps over their limits. Despite the many advantages of 3D bioprinting, the lack of a patent vascular network makes it difficult to grow 3d bio printed materials *in vivo* based only on diffusion of nutrients. However, cartilage tissue survives only on diffusion and thus should be a perfect candidate for 3D bioprinting, especially when co-cultured with bone marrow-derived mesenchymal stem cells (hBMSC) whose trophic role in cell differentiation and proliferation is widely appraised. Moller T. *et al* proved *in vivo* chondrogenesis by subcutaneously implanting 3D bio printed cellulose/alginate scaffolds co-cultured with hBMSC in rats. The scaffolds were followed-up histologically, immunohistochemically and showed enhanced deposits of glycosaminoglycans and human collagen II, leaving us with many ideas of how 3D bio printed cartilage could become a standard in reconstructive procedures (Moller T, Amoroso M, Hagg D, Brantsing C, Rotter N, Apelgren P, Lindahl A, Kolby L, Gatenholm P. *In Vivo* Chondrogenesis in 3D Bio printed Human Cell-laden Hydrogel Constructs. *Plast Reconstr Surg Glob Open* 2017; 5(2): e1227).

FOOD INTAKE - FAMILY INCOME IN A GROUP OF TEENAGERS FROM IAŞI "DIMITRIE CANTEMIR" HIGH SCHOOL (Abstract): Food intake is influenced by a series of factors, including family, income, school and mass-media. **Material and method**: A group of 78 teenagers were investigated using a food intake questionary, correlating the results with family income. **Results**: Our results show that the food intake is influenced more by family dietary habits rather than family income, with no significant differences between families with different socio-economic status. **Conclusion**: Educational programs for changing the nutritional habits must be implemented. **Key words**: FOOD INTAKE, INCOME, NUTRITIONAL HABITS

În abordarea generală a problematicii alimentaţiei adolescenţilor trebuie să pornim de la factorii ce o influenţează, factori reprezentaţi de familie, venit, grupul de prieteni, şcoală, mass-media. Familia reprezintă un model, mai ales pentru primii ani de viaţă. În acest mediu se formează unele obiceiuri alimentare ce persistă toată viaţa (1,2). Cu vârsta rolul familiei scade din ce în ce mai mult, apărând orientarea către grupul de prieteni. Venitul disponibil reprezintă o problemă mai ales pentru familiile sărace unde se consumă dominant alimente ce asigură doar necesarurile cantitative. Influenţa grupului de prieteni devine tot mai puternică în perioada adolescenţei. Prietenii asigură frecvent sprijinul necesar realizării unor schimbări majore în alimentaţie (modificări ce pot fi pozitive sau negative). Şcoala poate avea o influenţă pozitivă prin programele realizate (laptele şi cornul) sau în situaţia în care la cantină se oferă o masă caldă (3,4). Mass--media şi reclamele au un impact puternic asupra adolescenţilor care petrec mult timp în faţa televizorului. Frecvent, se oferă adolescenţilor anumite modele ce contribuie la formarea unei imagini nerealiste asupra aspectului corporal (se insită asupra tinerelor slabe şi a tinerilor cu mase musculare dezvoltate). Aspectele prezentate sunt complexe şi trebuie atent abordate. Doar o insistenţă din partea familiei, a medicului sau a şcolii nu rezolvă problemele, ci le încurcă şi mai mult.

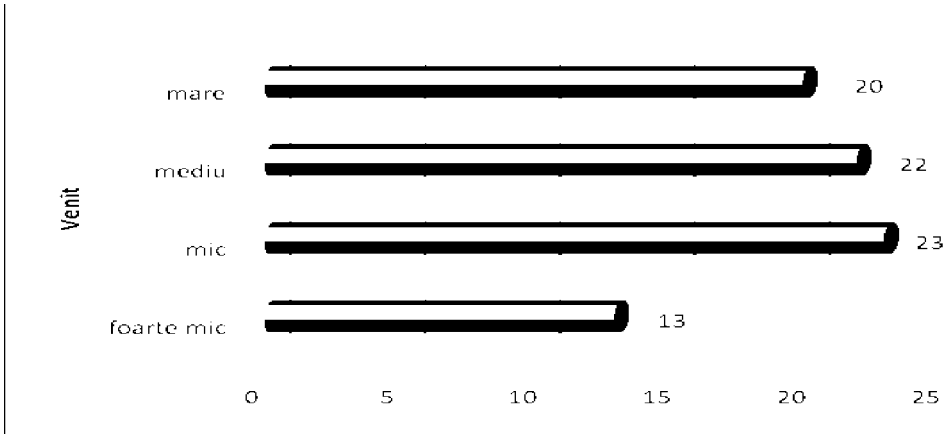

Fig. 1. Repartiţia cazurilor în funcţie de venitul pe membru de familie

TABELUL I
Frecvenţa consumului săptămânal de lapte

Consum	Zero	1 dată	2-3 ori	4-7 ori	Total
Venit foarte mic	1	2	8	2	13
Venit mic	1	6	11	5	23
Venit mediu	4	5	5	8	22
Venit mare	2	1	8	9	20
Total Nr.	8	14	32	24	78
%	10,25	17,94	41,02	30,76	

MATERIAL ŞI METODĂ

Studiul s-a realizat pe 78 de adolescenţi cu vârste cuprinse între 14 şi 16 ani ce învaţă la liceul D.Cantemir din Iaşi. Aceştia au completat un chestionar ce cuprinde întrebări referitoare la venitul pe membru de familie şi la alimentaţie. Venitul pe membru de familie a fost considerat foarte mic (sub 150 roni), mic (160 – 500 roni), mediu (500 – 1000 roni) sau mare (peste 1000 roni). Aprecierea alimentaţie s-a făcut cu ajutorul unui chestionar de frecvenţă săptămânală a consumurilor, prin care se apreciază aportul alimentar obişnuit şi nu cel real. Tehnica impune chestionarea subiectului în legătură cu frecvenţa consumului fiecărui aliment de pe o listă prestabilită. (5) Prelucrarea statistică a rezultatelor s-a realizat cu ajutorul testului Pearson.

REZULTATE ŞI DISCUŢII

In mod obişnuit venitul familiei influenţează alimentaţia, locuinţa şi calitatea îngrijirilor medicale acordate copiilor şi tinerilor. În familiile sărace alimentaţia asigură doar necesarul caloric, locuinţa este frecvent insalubră, iar tratamentele sunt urmate doar atunci când sunt gratuite. (6)

Pornind de la aceste considerente este important să cunoaştem, în primul rând nive-

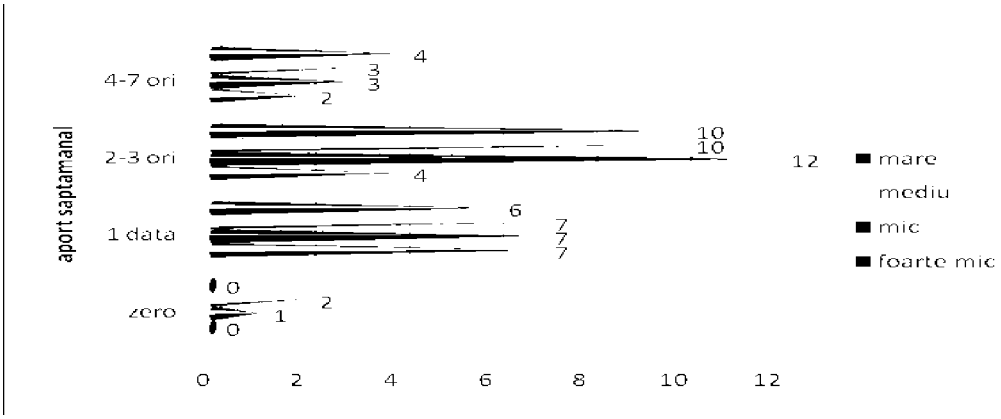

Fig. 2. Distribuţia cazurilor în funcţie de aportul săptămânal de brânzeturi

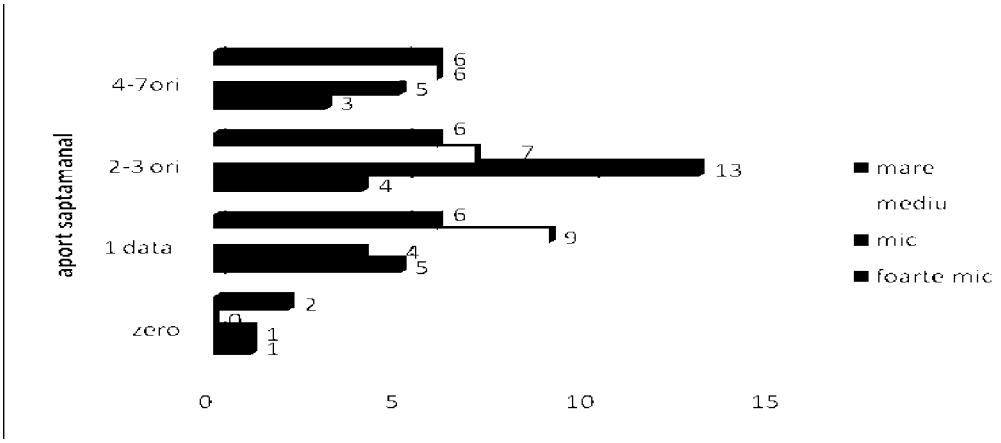

Fig. 3. Frecvenţa consumului de ouă la lotul de studiu

lul socio-economic al familiilor adolescenţilor din lotul de studiu. Distribuţia cazurilor în funcţie de venit este relativ uniformă, fiind dominante familiile cu un venit mic (29,48%) sau mediu (28,2%) (fig. 1).

Am insistat asupra consumului de alimente reprezentat de lapte, brânzeturi, ouă, cartofi şi fructe. Laptele este asigurat în majoritatea cazurilor de 2-3 ori pe săptămână (41,02%). Există situaţii în care acest aliment nu este consumat de adolescenţi (10,25%), astfel că se marcheaza varianta zero. La polul opus se plasează 30,76% tineri ce afirmă un consum de lapte de 4 – 7 ori pe săptămână. In funcţie de venit diferenţele constatate sunt nesemnificative statistic ($p > o,o5$, χ^2 - 11,968) ceea ce ne orientează către obiceiuri alimentare asemănătoare. Practic, în familiile cu venituri mari nu apare o creştere semnificativă a consumului săptămânal de lapte (tab. I).

Dominant, consumul săptămânal de brânzeturi este de 2-3 ori (46,15%) sau de 1 dată (34,61%). Atrag atenţia 3,84% răspunsuri de zero ce orientează către absenţa brânzeturilor din alinentaţia unor adolescenţi. La polul opus se plasează 15,38% răspunsuri de consum frecvent al acestor

TABELUL II
Consumul săptămânal de cartofi

Consum	Zero	1 dată	2-3 ori	4-7 ori	total
Venit foarte mic	0	2	5	6	13
Venit mic	0	8	10	5	23
Venit mediu	2	6	8	6	22
Venit mare	0	3	8	9	20
Total nr.	2	19	31	26	78
	2,56	24,35	39,74	33,33	

TABELUL III
Consumul săptămânal de fructe la elevii chestionaţi

Consum	Zero	1 dată	2-3 ori	4-7 ori	total
Venit foarte mic	0	1	2	10	13
Venit mic	0	1	4	18	23
Venit mediu	0	2	3	17	22
Venit mare	1	1	5	13	20
Total nr.	1	5	14	58	78
	1,28	6,41	17,94	74,35	

produse ce ajunge la de 4 – 7 ori pe săptămână (fig. 2). Testul Pearson indică diferenţe nesemnificative statistic ($p > o,o5$, χ^2 - 4,504) ceea ce ne orientează către ideea existenţei unor obiceiuri alimentare asemănătoare în familiile elevilor chestionaţi. Laptele şi brânzeturile sunt produse bogate în proteine, elemente minerale (în special calciu), lipide, glucide şi vitamine. Consumul lor este benefic pentru elevi, dar el depinde de obiceiurile alimentare ale familiei. La lotul de studiu nu apare o creştere a aportului acestor alimente în familiile cu un nivel economic ridicat.

Ouăle sunt alimente cu o mare valoare biologică (ele sunt bogate în proteine, lipide, vitamine, elemente minerale). La adolescenţi se recomandă un consum de un ou pe zi. La elevii chestionaţi aportul majoritar de ouă este de 2-3 ori pe săptămînă (38,46%). Situaţia cea mai gravă apare în 5,12% cazuri unde se bifează varianta zero ce indică absenţa acestui aliment din alimentaţia elevilor. Remarcăm doar 25,64% tineri ce au un aport adecvat de ouă (de 4-7 ori pe săptămână) (fig. 3).

Valorile sunt distribuite uniform în funcţie de venit, diferenţele constatate fiind nesemnificative statistic ($p > o,o5$, χ^2 - 7,392). Rezultatele obţinute relevă o puternică fixare în tradiţii, ceea ce duce la respectarea unor obiceiuri învăţate în copilărie şi perpetuarea lor în propria familie.

În alimentaţie produsele de origine animală sunt asociate cu cele de origine vegetală. Cartoful este o legumă aparte pentru ţara noastră, deoarece se cultivă pe arii extinse. Consumul majoritar de cartofi este de 2-3 ori pe săptămână (39,74%) sau de 4-7 ori (33,33%). Răspunsul zero este prezent în 2,56% din cazuri ceea ce ne atrage atenţia în mod deosebit, mai ales pentru zona Moldovei unde cultivarea cartofului este bine dezvoltată. Diferenţele nesemnificative statistic ($p > o,o5$, χ^2 - 11,035) ne orientează tot către obiceiuri alimentare ase-

mănătoare. La lotul de studiu observăm un consum asemănător de cartofi, chiar dacă familiile au posibilităţi financiare diferite. Familiile elevilor chestionaţi sunt profund ancorate în tradiţiile învăţate de la părinţi, astfel că nu reacţionează la schimbarea nivelului economic prin modificarea alimentaţiei (tab. II).

Fructele proaspete asigură un aport important de vitamină C şi oferă un aport caloric mic ceea ce este un element favorabil pentru menţinerea constantă a greutăţii corporale. La lotul de studiu consumul dominant de fructe este de 4-7 ori pe săptămână. Este alarmantă situaţia a 1,28% elevi ce afirmă absenţa consumului de fructe. Diferenţele nesemnificative constatate ($p > o,o5$, χ^2 - 5,597) ne orientează tot către obiceiuri alimentare asemănătoare. Cumpărarea fructelor nu este o problemă în anumite familii, dar consumul lor este dependent de tradiţia familiei (tab. III).

CONCLUZII

La lotul de studiu consumul alimentar este asemănător chiar dacă venitul pe membru de familie este diferit. Familiile cu un venit foarte mic fac eforturi pentru a asigura o alimentaţie adecvată copiilor lor. Din păcate, în familiile cu un venit mediu sau mare nu se observă un salt calitativ. Elaborarea unor programe naţionale de modificare a obiceiurilor alimentare trebuie să pornească de la particularităţile propriei populaţii (chiar a celor de la nivel local – regiuni istorice). Programele care nu iau în calcul aceste particularităţi au prea puţine şanse de reuşită.

EXPERIMENTAL STUDIES ON FORMULATION OF MODIFIED-RELEASE AMIODARONE TABLETS (Abstract): Drug formulations and their technological processes must ensure quality and reproducibility in the conditions of the information transfer between research institutions and industry for the preparation of large amounts of pharmaceutical product. **Aim:** Analysis of the influence of formulation factors on flow parameters of the powder mixture in order to obtain amiodarone tablets. **Material and methods:** Data fitting and calculation of statistical indicators for the validation of the experimental plan. The study was carried out using the MODDE 10.1 optimization software. The quantitative variables were amiodarone, amiodarone complex with hydroxypropyl-β-cyclodextrin, Kollidon® SR, Chitosan, Aerosil®, magnesium stearate, and Avicel®, while the qualitative variables were the following flow and compressibility parameters of the mixtures subjected to compression: flow time, coefficient of friction, angle of rest, Hausner index and Carr index. The matrix for optimizing the formulation based on the presented parameters was based on a D-optimal experimental design. **Results and Discussion:** The results of the study on the influence of formulation factors on flow time confirmed that Kollidon® SR concentration levels decrease the flow time, also confirmed for Chitosan but on a smaller scale. Of the formulation factors, Avicel® and Kollidon® SR variables had the greatest influence on the friction coefficient, increasing the concentration of these parameters generating a decrease in the friction coefficient. **Conclusions:** The use of experimental designs in the formulation of amiodarone tablets and the formulation analysis based on flow and compressibility parameters allows establishing a hierarchy based on the importance of qualitative variables, influenced by quantitative variables, to identify the optimal formulation and technology for the preparation of tablets. **Keywords:** AMIODARONE, MODIFIED RELEASE, FORMULATION, EXPERIMENTAL PLAN.

The qualitative formulation elements of a pharmaceutical product include documentation of physicochemical and biopharmaceutical properties of both drug substances and excipients, as well as establishing optimum working conditions that would facilitate the transfer of the pharmaceutical formulation from the research and development phases to the production stage during industrial process scale-up.

Besides being a screening technique, optimization is a selection method of the best combination of raw materials and of the most appropriate technological process,

in order to obtain the optimal formulation of the pharmaceutical product (1).

The formulation of drugs and their technological processes must ensure quality and reproducibility under the conditions of large-scale preparation. The number of experiments necessary to investigate the drug formulation should be minimized in order to collect the technical information specific to the formulation. The use of experimental plans and optimization methods, which ensure the progressive acquisition of information, reduces the number of experiments without affecting the quality of results. Experimental plans effectively minimize classical method errors by changing the level of all variables in each experiment in a programmed and justified manner (2, 3). The advantages of using experimental plans are: reducing the number of experimental determinations, the possibility of studying a large number of variables, the possibility of identifying possible interactions between various factors, the possibility of generating optimal values for each variable, obtaining a good accuracy of results and optimizing the drug formula in terms of quality, quantity, technology (4, 5).

The aim of the study was to analyze the influence of the qualitative formulation factors on the flow parameters of the powder mixture in order to obtain modified-release tablets with amiodarone complex with hydroxypropyl-β-cyclodextrin (6-10).

MATERIAL AND METHODS

Data fitting and calculation of statistical indicators for the validation of the experimental plan was carried out using the MODDE 10.1 optimization program. The quantitative variables were amiodarone, amiodarone complex with hydroxypropyl-β-cyclodextrin, Kollidon® SR, Chitosan, Aerosil®, magnesium stearate, Avicel®, while the qualitative variables were the following flow and compressibility parameters of the mixtures subjected to compression: flow time, coefficient of friction, angle of rest, Hausner index and Carr index (11-14).

The study of the influence of formulation factors on flow and compressibility parameters of the powder mixtures subjected to compression was carried out in two stages (15, 16). During the first stage, the reduced experimental plan, which included seven factors on three levels, was implemented. It enabled identifying the factors that influence the process of tablet manufacturing.

The study focused on the influence of the independent quantitative variables (tab. I) on the qualitative variables (17-20) (tab. II).

TABLE I

Quantitative variables

Factors	Code	%		
		1	2	3
Amiodarone complex	X1	0	33.33	-

RESULTS AND DISCUSSION

During the study, an experimental plan that included seven factors (independent variables) and more than three levels were used.

The influence of formulation factors on the mechanical strength can be assessed by the coefficients of polynomial equation (mathematical model) which was carried out using the experimental fitting (centered and scaled factors).

According to the data obtained from the analysis of the influence of formulation factors according to the reduced experimental plan it was appreciated that the greatest influence on the characteristics of matrix tablets was carried by the pharmacotechnical variables X3 and X7 (Kollidon® SR and Avicel®).

The results on the influence of quantitative factors on flow time confirmed that the concentration levels of Kollidon® SR decrease the flow time, also noticed for Chitosan but on a smaller scale.

Of the analyzed formulation factors, Avicel® was the variable that had the greatest influence on the friction coefficient. Increasing its concentration resulted in a decrease of the friction coefficient.

The Kollidon® SR variable had a significant positive influence on the friction coefficient, increasing Kollidon® SR concentration in the formulation resulting in higher friction coefficients.

The pharmacotechnical parameters - diameter and thickness - were not significantly influenced by the independent variables of the experimental plan, as they were primarily defined by the working conditions and the technical characteristics of the tableting machine.

Very good results were obtained for the Hausner ratio, which had a validity value model very close to 1 (tab. VI). According to the data presented in table VII, good results were also found for the friction coefficient, angle of rest, flow time and Carr index.

CONCLUSIONS

We have used experimental plans in the formulation of amiodarone tablets and the analysis of formulation based on flow and compressibility parameters, which allowed us to establish a hierarchy based on the importance of quantitative variables, as they influenced the qualitative variables, in order to achieve optimal formulation and technology for tablet manufacturing.

We found Avicel® to have the greatest influence on tablet formulation, followed by Kollidon® SR and Chitosan. They positively influenced the values of the analyzed qualitative variables that defined the preparation of the tablets by direct compression method.

Taking also into account the results of the analysis of the influence of formulation factors on flow properties, it was considered that the independent variables were selected in corresponding concentration ranges to obtain matrix tablets.

The results of the experimental plan recommended lower optimal values corresponding to Kollidon® SR 40% and Chitosan 3%.

SOME EPIDEMIOLOGICAL AND FORENSIC ASSESSMENTS ON CASES OF DOMESTIC VIOLENCE, RECORDED IN PIATRA NEAMŢ, BETWEEN 1997-2009 (Abstract): Authors highlighted some aspects regarding domestic violence in an urban community, during 13 years. **Material and method**: The study included 31406 individuals from the county, with various aggressions, from which 1433 (53.43%) from Piatra Neamţ Town and 2682 (8.53%) were victims of domestic violence < 20-61 aged. **Results**: Domestic violence prevalence in Piatra Neamţ Town, comparatively with county, had values of 6.21% in 1997 and 7.10% in 2009. Cumulatively for 13 years, female victims were 1081 (75.43%), comparatively with males 352 (24.56%). A percent of 79.51% of cases interested 21-60 aged active social groups. The gravity of domestic violence lesions were distributed in 4 categories, from 10 to 61 days of hospitalization. **Conclusions**: Negative social economical involvements of domestic violence for individual, family and community, presented various aspects, some of them difficult to quantify (hospitalisation, absenteeism, temporary work incapacity a.s.o). **Key words**: DOMESTIC VIOLENCE, PREVALENCE, FORENSIC MEDICINE

Violenţa umană, cu expresia ei domestică, este o componentă a naturii umane care, însă, poate şi trebuie prevenită şi combătută (1,2,3). Perioada de tranziţie a României spre economia de piaţă a determinat mutaţii profunde de ordin politic şi socio-economic care s-au asociat şi cu schimbări în instituţia familiei, exprimată adeseori printr-o frecvenţă tot mai mare a exceselor comportamentale, dominate de violenţă fizică sau psihologică, cu impact negativ asupra evoluţiei vieţii de familie. Deşi este un fenomen care a însoţit dintotdeauna construirea şi dinamica familiei, doar în ultimele decenii, ştiinţele sociale şi juridice se referă la reglementările, de nivel naţional şi internaţional, privind violenţa domestică. Astfel, OMS defineşte violenţa ca fiind ameninţarea sau utilizarea intenţionată a forţei fizice sau a puterii împotriva propriei persoane, a unei alte persoane, împotriva unui grup sau împotriva comunităţii şi care antrenează un risc crescut de a produce un traumatism, un deces, o daună psihologică, o dezvoltare anormală sau o privaţiune (4, 5, 6). Între numeroasele documente elaborate la nivelul Comunităţii Europene, important este cel din anul 2004, privind programul de acţiune Dafne II, pentru perioada 2004-2008, urmat de actualizări, care includ măsuri preventionale şi combatere a violenţei împotriva copiilor, tinerilor şi fe-

TABELUL I

Distribuţia anuală, a cazurilor de violenţă domestică, comparativ, în judeţul şi municipiul Piatra Neamţ, în perioada 1997-2009

Total cumulativ	**31.406**	**2682**	**8,53**

meilor, pentru protecţia victimelor şi a grupurilor cu risc.

Şi în România, relaţiile din cadrul familiei au fost reglementate şi protejate dintotdeauna dar în ultimii ani, Codul Penal a inclus prevederi de protejare a familiei împotriva violenţei domestice iar Hotărârea Guvernului din anul 2009 se referă la măsurile de prevenire şi combatere a violenţei în familie, care vor fi implementate prin Autoritatea Naţională pentru protecţia familiei şi a drepturilor copilului (7, 8, 9, 10).

Lucrarea îşi propune să evidenţieze unele aspecte privind violenţa domestică într-o comunitate urbană din Moldova.

MATERIAL ŞI METODE

În cercetările noastre am inclus un lot de 31406 persoane din judeţul Piatra Neamţ, supuse diferitelor agresiuni dintre care 1433 (53,43%) au provenit din municipiul Piatra Neamţ, iar 2682 (8,53%)au fost victime ale violenţei domestice având vârsta de < 20 la = 61 ani, şi 1081 (75,43%) fiind de sex feminin.

Informaţiile au fost obţinute de la Serviciul Judeţean de Medicină legală şi Fundaţia „Columna", Piatra Neamţ, pentru perioada 1997-2009.

Prelucrarea şi interpretarea datelor acumulate a fost realizată prin metode epidemiologice (ancheta, incidenţa şi prevalenţa) şi statistico-matematice (regresia liniară, probabilitatea statistică etc.).

REZULTATE ŞI DISCUŢII

1. Distribuţia anuală a victimelor diverselor agresiuni, cu violenţă domestică, în judeţul şi municipiul Piatra Neamţ. Din totalul cumulativ pentru cei 13 ani, agresiunile au totalizat 2682 (8,53%) pentru municipiul Piatra Neamţ dar dintre acestea, violenţa domestică a înregistrat 1433 (53,43%) cazuri, dovedind existenţa unor factori de risc cu o pondere semnificativ mai ridicată în mediul urban ($p \leq 0,05$).

În municipiul Piatra Neamţ, atât pentru victimele agresiunilor variate cât şi cele ale violenţei domestic, valorile prevalenţei anuale au avut diferenţe nesemnificative ($p = 0,05$).

Din totalul victimelor agresiunilor pentru întregul judeţ, prevalenţa violenţei domestice, în municipiul Piatra Neamţ, a avut valori de 6,25% în anul 1997 şi 7,10% în 2009.

În perioada luată în studiu, din 2682 cazuri de violenţă domestică înregistrate

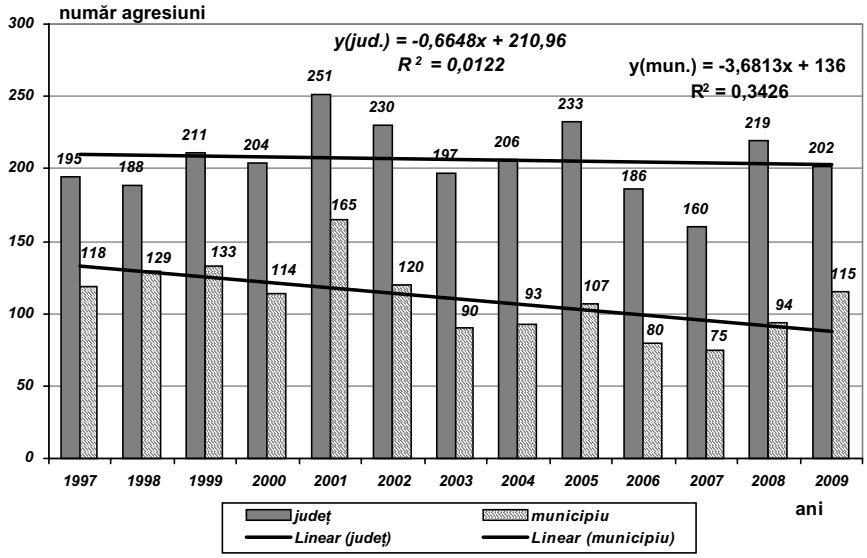

Fig. 1. Distribuţia anuală, comparativă, a cazurilor de violenţă domestică, din judeţul şi municipiul Piatra Neamţ, în perioada 1997-2009

la nivel judeţean 1433 (53,43%) s-au produs în mediul domestic din municipiul Piatra Neamţ (tab. I, fig. 1).

Ancheta epidemiologică şi medico-legală a evidenţiat cauzele principale ale prevalenţei ridicate a cazurilor de violenţă domestică în municipiul Piatra Neamţ, ca fiind în relaţie cu deteriorarea situaţiei socio-economice (scăderea veniturilor, şomaj) care a determinat creşterea nivelului agresivităţii, nemulţumirilor şi neînţelegerilor din mediul familial. De asemenea, urmare a realizării unor programe informative-educaţionale, a crescut adresabilitatea victimelor spre structurile medico-judiciare.

2. Analiza repartiţiei pe sex, a cazurilor de violenţă domestică, a dovedit cu un nivel ridicat de semnificaţie statistică ($p < 0,005$), faptul că femeile au suportat cel mai frecvent agresiunile intrafamiliale iar bărbaţii, îndeosebi, cele extrafamiliale.

Cumulativ, pentru cei 13 ani incluşi în studiu, victimele violenţei în familie au înregistrat 1081 (75,43%) pentru femei faţă de 352 (24,56%) la bărbaţi. Distribuţia anuală arată diferenţe nesemnificative în cazul femeilor ($p = 0,05$) dar acestea sunt evidenţiate când se compară situaţia între cele două sexe.

3. Repartiţia pe grupuri de vârstă. Violenţa domestică a fost semnalată, cu valori diferite în toate grupurile de vârstă. Din total cumulativ, 79,51% din cazuri au interesat grupurile active social (21-60 ani), urmate de = 61 (14,44% şi 0-20 (6%) (fig. 2).

Victimizarea vârstnicilor, precum şi a grupurilor de vârsta de până la 20 ani, prezintă particularităţi fizice şi psihologice. Îndeosebi, consecinţele asupra dezvoltării psiho-comportamentale sunt deosebit de grave în cazul implicării, directe sau indirecte, în actele de violenţă domestică a copilului.

4. Evaluări asupra gravităţii leziunilor produse prin violenţa domestică. În raport cu prevederile legislaţiei, variatele leziuni neletale produse prin acte de violenţă domestică sunt evaluate în ce priveşte gravitatea în raport cu numărul zilelor de îngrijiri medicale necesare vindecării, şi incluse în 4 categorii: *uşoare* (excoriaţii, echimoze, hematoame, plăgi superficiale); *medii* (fracturi costale, plăgi sau hematoame compli-

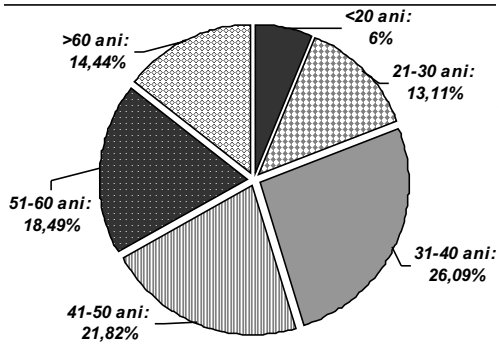

Fig. 2. Distribuţia pe grupuri de vârstă a cazurilor de violenţă domestică înregistrate, cumulative, în municipiul Piatra Neamţ, în perioada 1997-2009

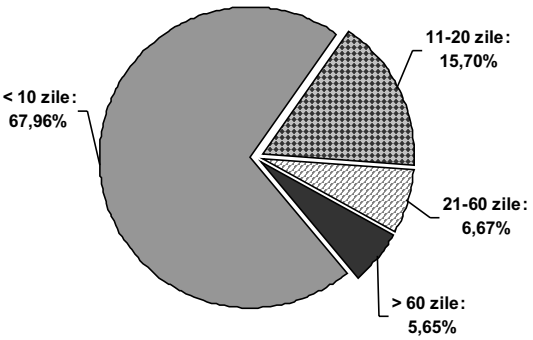

Fig. 3. Eşalonarea, pe categorii de gravitate, a leziunilor produse în 1433 cazuri de violenţă domestică, înregistrate în municipiul Piatra Neamţ, cumulativ în perioada 1997-2009

cate) ; *grave* (contuzie cerebrală medie, fracturi complicate) şi *foarte grave* (traumatism cranio-cerebral cu fracturi multiple, contuzie cerebrală gravă, arsuri, fracturi complicate). În raport de categoria de gravitate numărul de zile îngrijiri medicale vor varia de la 10 la peste 61 zile (Fig. 3).

Implicaţiile socio-economice negative ale violenţei domestice, pentru individ, familie şi comunitate, prezenta numeroase aspecte, unele dificil de cuantificat (costuri pentru : consultaţia medico-legală şi a altor specialităţi, investigaţiile paraclinice, spitalizările, absenteismul ocupaţional, incapacitatea temporară de muncă, perturbările grave ale vieţii de familie etc..

Din lotul de 1433 cazuri de violenţă domestică, 253 (17,65%) au necesitat spitalizări cu durată de 1-58 zile iar 413 (28,82%) au apelat la investigaţii variate în ambulator.

Studiul pe un sublot de 364 cazuri a arătat că 147 (40,38%) cazuri de violenţă în familie s-au finalizat prin divorţ şi 47 (12,91%) cu diferite acţiuni în instanţele de judecată.

Analiza situaţiei socio-economică a victimelor violenţei domestice evaluată pe un sublot de 388 cazuri, a evidenţiat că 75 (22,18%) nu aveau nici un suport financiar ; 125 (36,90), cu salariu minim ; 115 (34,02) cu salariu mediu sau pensie şi numai 23 (6,89%) posedau un venit care depăşea salariul mediu pe economie.

Rezultă că proporţii importante (57,98%) dintre victimele violenţei domestice sunt dependente financiar de agresor ; motiv pentru care un număr semnificativ de cazuri nu sunt raportate, la acestea adăugându-se costurile imposibil de raportat pentru a beneficia de prestările medico-legale şi cele dependente de acestea.

CONCLUZII

Transformările profunde şi alerte, înregistrate la nivel planetar, afectează grav multe din aspectele de echilibru în familie, îndeosebi pe seama unor dificultăţi socio-economice în strânsă corelaţie cu variate modificări comportamentale.

Violenţa domestică semnalată de-a lungul vremurilor, a cunoscut în ultimele decenii, o recrudescenţă semnificativă în toate ariile geografice, cu o prevalenţă mai ridicată în mediul urban, unde relaţiile interumane au particularităţi care, adesea, favorizează violenţa. Astfel, în municipiul Piatra Neamţ, în perioada 1997-2009, violenţa domestică a înregistrat 53,43% din totalul agresiunilor semnalate la nivelul judeţului, cu evidenta afectare a femeilor (75,43%)

comparativ cu bărbaţii (24,56%).

Cumulativ pentru cei 13 ani luaţi în studiu, grupurile de vârstă cele mai active socio-economic (21-60 ani) au fost afectate de violenţa în familie 79,51% din total cazuri.

În cele 6% din cazuri consecinţele asupra dezvoltării psiho- comportamentale sunt deosebit de grave în cazul implicării, directe sau indirecte, în actele de evidenţa domestică a copiilor şi adolescenţilor.

În 1433 cazuri de violenţa domestică, gravitatea leziunilor (uşoară, medie, gravă, foarte gravă) a fost evaluată după numărul de zile de spitalizare (< 10, 11-20, 21-60, = 61) având proporţii de: 15,70; 60,67; 5,65%.

Implicaţiile socio-economice negative ale violenţei domestice, pentru individ, familie şi comunitate, au prezentat numeroase aspecte, unele dificil de cuantificat (costuri pentru: consultaţiile medico-legale şi a altor specialităţi, investigaţiile paraclinice, spitalizările, absenteismul ocupaţional, incapacitatea temporară de muncă, perturbările grave ale vieţii familiale etc.).

IN MEMORIAM

IN MEMORIAM, DR. EMIL GHEORGHIȚĂ

Dr. Emil Gheorghiță, passed away in November 2018. He was an eminent physician, founder of clinical hospitals and medical schools, a pioneer in the medical world and, above all, a very special man, whose generosity, talent, breadth of knowledge and kindness endeared him to colleagues, patients, relatives and friends alike.

He started his residency training in Obstetrics and Gynecology at the "Cuza-Vodă" Clinical Hospital for Obstetrics and Gynecology in Iași, under the direct guidance of Professor Vasile Dobrovici, a famous specialist who became his mentor and whom he had always held in high esteem. During the same period, he was entrusted with the position of director of the same hospital, which he completely reorganized and modernized.

In 1975, Dr. Emil Gheorghiță founded, together with Professor Gheorghe Teleman, the "Elena Doamna" Clinical Hospital of Obstetrics and Gynecology which he coordinated with professionalism and abnegation until the late 1990s. Within this hospital, Dr. Emil Gheorghiță set up (with Dr. Dan Sorin Tomoșoiu), organized and led the Regional Centre for Reproductive Health and Family Planning, which soon became a national landmark in this field.

In 1976, he defended his doctoral thesis entitled *Visual Disorders in Puerperality*, a topic that had not been treated before, which impressed at that time by its originality and modernity of approach. Besides his medical and organizational activity, Dr. Gheorghiță found the time to sit for further examinations in order to become a "primary physician" in the Romanian medical system (which corresponds, more or less, to a British "consultant") as well as a university reader. Although he successfully passed both exams, he could not pursue an academic career because all the academic positions for which contests had been organized in universities were blocked. Even so, his scientific concerns materialized not only in the books and monographs which he coauthored, or in the numerous articles that he published in specialized journals, but also in his initiative of organizing the "Vasile Dobrovici" National Conference, an outstanding scientific event that has gathered specialists in the field up to this day.

With over 40 years of medical experience as an obstetrician-gynecologist, he helped thousands of women fulfil their dream of having a healthy baby. He brought the smile on the lips of other thousands of women who asked him for help, some of them being saved from certain death.

His love of life and people, his mentoring vocation and talent were manifest both in the way he practiced his profession and in his constant wish to share his professional knowledge with his younger colleagues. Whatever the team he may have worked with, he encouraged an atmosphere of emulation and understanding, of mutual trust, love of life and dynamism. Through his way of stimulating his collaborators and disciples, he gained their confidence and gratitude. An altruistic and life-loving spirit, he enjoyed being surrounded by friends, whom he cherished, loved and helped. All that remains to those who loved and admired him is to follow his example and decipher with the same meticulousness the holy dimension of medical care.

2. Serviciul de Radiologie

AMYAND HERNIA (Abstract) : The Amyand hernia is an uncommon variant of the inguinal hernia, rarely recognised before the surgical treatment because of the confusion with a strangled hernia. In spite of this, the clinical presentation seems to follow a well determined pathway, so it is possible to state that the uncorrect diagnosis is to be attributed to the ignorance of this variant of hernia. We present two consecutive case reports of acute appendicitis founded in an inguinal hernia sac. The clinical presentation depended on the inflammation extension inside the hernia sac and the presence or not of peritoneal contamination. The patients were admitted for a painful pseudotumor in the inguinal region with irreducibility, mimicking strangled inguinal hernia with acute inflammatory syndrome. Intraoperatively we have found a hernia sac with a phlegmonous/gangrenous appendix inside. Appendectomy was performed, followed by hernioplasty (retrofunicular technique) without prosthetic material). The operation followings were favorable. We conclude that amyand hernia must be considered as differential diagnosis of apparently strangled inguinal hernias. Technical precautions and antibioprophylaxy applied during surgery may prevent septic complications after hernioplasty. The hernia repair must be performed without prosthetic material and using exclusively resorbable sutures. **Key words:** INGUINAL HERNIA, ACUTE APENDICITIS, AMYAND HERNIA

Apendicita acută într-un sac de hernie inghinală, denumită hernie Amyand, este o afecţiune rară, iar când aceasta apare, este deseori diagnosticată eronat ca hernie strangulată.

MATERIAL ŞI METODĂ

Au fost selectate şi analizate retrospectiv două cazuri de hernie inghinală, internate şi operate în urgenţă în Clinica a III-a Chirurgicală a Spitalului "Sf. Spiridon". La aceste cazuri, intraoperator s-a descoperit conţinut herniar reprezentat de cec împreună cu apendicele cecal. Acestea prezentau complicaţii mecanoinflamatorii (ireductibilitatea conţinutului prin strangulare şi inflamaţie acută apendiculară cu aderenţe inflamatorii la sacul herniar) aspecte ce încadrează leziunile în categoria herniilor Amyand.

Prezentare caz 1

Pacientul I.C. de sex masculin în vârstă de 67 ani, cu antecedente patologice cardiovasculare, se internează cu semne clinice de subocluzie intestinală. Examenul local evidenţiază o hernie inghinofuniculară ireductibilă. Se intervine chirurgical în condiţiile unei antibioprofilaxii cu Cefoperazonă + Sulbactam 2 g, asociat cu Metronidazol 0,5 g, în două prize (la inducţie şi după 6 ore). Intraoperator se descoperă un sac herniar inghinal drept, cu un conţinut herniar reprezentat de cec şi apendice cecal, conţinut ce este strangulat şi aderent la sacul herniar la nivelul coletului. Peretele

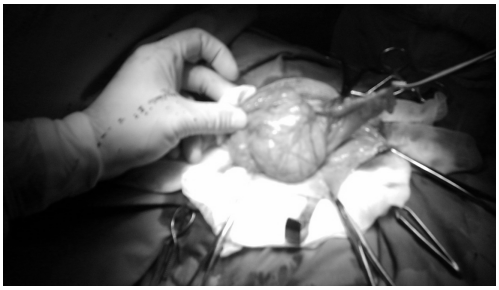

Fig. 1. Cec şi apendice cecal cu leziuni inflamatorii flegmonoase în sacul herniar

cecal şi apendicele prezentau aspect edematos-congestiv, cel mai probabil, datorită stazei venoase cauzate de strangularea la nivelul coletului herniar (fig. 1). Se eliberează şi se reduce conţinutul sacular prin secţionarea inelului herniar, gest urmat de apendicectomie cu bont legat şi înfundat şi reintroducerea cecului în cavitatea peritoneală. Cura herniei se realizează printr-un procedeu retrofunicular cu sutura aponevrozei marelui oblic şi a tendonului conjunct la ligamentul Cooper. Rezultatul anatomopatologic al apendicelui relevă modificări inflamatorii în stadiul cataral spre flegmonos şi hipetrofia foliculilor limfoizi.

Prezentare caz 2

Pacientul P.M. de sex masculin, în vârstă de 58 ani, având comorbidităţi importante (obezitate gradul II, hipertensiune arterială şi cardiopatie ischemică cronică dureroasă), şi antecedente de hernie inghinală dreaptă diagnosticată de aproximativ 1 an, se prezintă la Unitatea de Primire Urgenţe (UPU) a Spitalului „Sf. Spiridon” pentru tumefiere şi durere la nivelul regiunii inghinoscrotale drepte, apărute brusc de aproximativ 24 ore, cu tranzit intestinal prezent. Examenul clinic al abdomenului, dificil de efectuat datorită obezităţii, relevă la nivelul regiunii inghinoscrotale drepte o formaţiune pseudotumorală de dimensiuni mari 15/7 cm, renitentă, dureroasă, ireductibilă spontan sau la manevra de taxis, cu tegumentele supraiacente congestive. Testele de laborator evidenţiază leucocitoză importantă (17.000/mmc). Examinarea ultrasonografică abdominală este dificilă şi neconcludentă. Radiografia abdominală simplă în ortostatism relevă câteva nivele hidroaerice la nivelul intestinului subţire. Aspectul clinic coroborat cu leucocitoza a orientat diagnosticul spre o hernie inghioscrotală dreaptă ireductibilă, cu probabilitate de strangulare de ansă intestinală ileală. S-a intervenit chirurgical în urgenţă, sub anestezie generală, în condiţiile aceleiaşi antibioprofilaxii standard. Abordul inghinal drept a evidenţiat un sac herniar oblic extern prelungit până la nivelul hemiscrotului drept de aproximativ 17/ 4 cm, ce conţine lichid cu aspect tulbure, filant, fetid, în care se regăsesc apendicele cecal şi parţial cecul. Apendicele a prezentat leziuni inflamatorii în stadiul flegmonos, cu aderenţe inflamatorii şi false membrane, cu vârful acolat la capătul sacului herniar ; se mai observă modificări de tiflită, cu o zonă de necroză de 3/2 cm în apropierea inserţiei apendiculare (fig. 2). S-a practicat apendicectomie şi excizie parcelară de perete cecal, urmate de cecorafie cu mezoplastia suturii. Ulterior se disecă şi se rezecă sacul herniar mult îngroşat (aproximativ 1 cm grosime) prin modificări inflamatorii. Refacerea peretelui se realizează printr-un procedeu retrofunicular (Bassini modificat), cu fire lent rezorbabile Vicryl nr. 2. Exami-

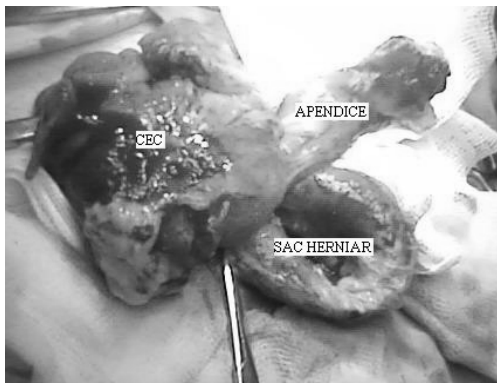

Fig. 2. Cec şi apendice cecal cu inflamaţie gangrenoasă

narea microscopică a confirmat stadiul flegmonos al inflamaţiei apendiculare şi necroza parcelară a peretelui cecal excizat.

Rezultatele tratamentului chirurgical al celor două cazuri au fost favorabile, fără complicaţii septice peritoneale sau la nivelul plăgii operatorii.

DISCUŢII

Prima apendicectomie a fost efectuată de Claudius Amyand (1,2) în 1735 la Spitalul St. George, Londra. Pacientul era un băiat de 11 ani care s-a prezentat cu o hernie inghinală şi fistulă stercorală la acest nivel. Apendicele cecal este estimat a fi găsit în mai puţin de 1% din cazuri cu hernii inghinale la adult. Descoperirea unei apendicite acute într-un sac de hernie inghinală este şi mai rară. D'Alia et al. (3) raportează o rată de 0,08% în 1341 hernii inghinale operate, iar Ryan (4) raportează doar 11 cazuri de apendicită acută asociată la 8.902 pacienţi cu hernii inghinale. Aspectul clinic al acestei afecţiuni variază în funcţie de intensitatea inflamaţiei la nivelul apendicelui şi de prezenţa sau nu a contaminării peritoneale (5,6). Poziţia apendicelui faţă de cec este variabilă : există tipuri de apendice cu situare retrocecală, pelvină, preileală, sau poziţie dreaptă pericolică (poziţia înaltă cecală). Nu s-au identificat poziţii ale apendicelui predispozante pentru angajarea într-un sac herniar inghinal (7,8). Rămâne nedemonstrată corelaţia între aceste variante anatomice de poziţie ale apendicelui şi angajarea acestuia în sacul herniar inghinal cu apariţia apendicitei acute. Fiziopatologia herniei Amyand adaogă la mecanismul obstrucţiei lumenului apendicular de către un coprolit şi strangularea apendicelui la nivelul coletului sacului herniar. Relaţia între încarcerarea şi inflamarea apendicelui nu este deplin dovedită (1,9). Majoritatea autorilor admit însă scenariul conform caruia imediat ce apendicele intră în sacul herniar, acesta devine vulnerabil la traumă iar ulterior este reţinut prin aderenţe inflamatorii (10,11). Angajarea cecului şi apendicelui în sacul herniar favorizează în plus staza conţinutului cecal şi apendicular sau chiar obstrucţia lumenului apendicular. Aportul sanguin poate fi substanţial afectat şi împreună cu edemul interstiţial să conducă la inflamarea apendicelui şi proliferarea bacteriană în lumenul şi în peretele acestuia. Contractarea muşchilor abdominali şi alte creşteri bruşte ale presiunii abdominale pot duce la compresia apendicelui şi inflamarea sa ulterioară. Anamneza şi examenul clinic orientează diagnosticul spre hernia inghinală încarcerată cu peritonită localizată, saculară (4,5). Prezenţa unui panicul adipos abundent face dificilă examinarea clinică şi decelarea semnelor inflamatorii locale sau a celor de abdomen acut. Contaminarea marii cavităţi peritoneale de la lichidul septic intrasacular conduce la apariţia fenomenelor de peritonită. Diagnosticul apendicitei acute este afirmat pe baza exmenului clinic ; prin urmare şi în cazul apendicitei acute în sac herniar examenul clinic local ar trebui sa stabilească diagnosticul, însă datorită rarităţii situaţiei anatomoclinice, raţionamentul care ar trebui sa ne conducă la această entitate este eronat şi, în consecinţă, diagnosticul constituie o surpriză intraoperatorie. Confirmarea diagnosticului la momentul deschiderii sacului herniar impune măsuri sporite de izolare şi protejare a câmpului operator cu evitarea contaminării elementelor anatomice extrasaculare (12). Antibioprofilaxia este de dorit a fi începută la inducţia anestezică în contextul prezenţei semnelor inflamatorii locale (13). Tratarea sacului herniar (disecţia de elementele funiculului spermatic şi rezecţia) poate fi dificilă dacă peritoneul sacular prezintă modificări inflamatorii importante (13,14). Înaintea ligaturii sau suturii acestuia la nivelul coletului, este necesară inspectarea conţinutului marii cavităţi peritoneale. Timpul septic de la apendicectomie contraindică utilizarea materia-

lului protetic sau a firelor de sutură nerezorbabile pentru refacerea peretelui inghinal.

CONCLUZII

Hernia inghinală cu apendicită acută în sacul de hernie este o variantă rară, iar când aceasta survine, este deseori diagnosticată eronat ca hernie strangulată. Tratamentul implică apendicectomia prin herniotomie urmată de cura herniei per primam fără material protetic.

NEW POLYMER-DRUG SYSTEMS BASED ON NATURAL AND SYNTHETIC POLYMERS (Abstract) : The great versatility of polymers makes them very useful in the biomedical and pharmaceutical fields. The combination of natural and synthetic polymers leads to new materials with tailored functional properties. The aim of this work consists in the preparation of new drug delivery system based on chitosan (natural polymer) and polybetaines (synthetic polymers), by a simple process, well known in the literature as complex coacervation methods. Also, the adsorption and release studies of two antibiotics as well as the preservation of their bactericidal capacities were performed. **Key words** : CHITOSAN, POLIBETAINES, COMPLEX COACERVATION METHOD, ANTIBIOTICS

LEVEL OF KNOWLEDGE AND ATTITUDES AMONG DENTISTS REGARDING THE USE OF CBCT IN DENTAL PRACTICE (Abstract): Cone Beam Computed Tomography (CBCT) is a revolutionary imaging technology in modern dentistry, providing detailed three-dimensional visualization of dental and maxillofacial structures. Despite its advantages, CBCT adoption is influenced by several factors, including costs, training, and professional experience. This study **aimed** to assess the level of knowledge and attitudes of dentists regarding CBCT usage in dental practice and identify the factors influencing its adoption. **Materials and methods**: A cross-sectional study was conducted using a structured online questionnaire completed by 113 dentists. The questionnaire collected data on demographic characteristics, professional experience, frequency of 2D and CBCT use, perceived benefits and limitations, and training levels. Statistical analyses were performed using *SPSS 26.0*, with a significance level set at $p < 0.05$. **Results:** The results showed that CBCT use was more frequent among specialists (46% weekly use) compared to non-specialists (33.3% daily use of 2D radiographs). Key advantages of CBCT, such as enhanced diagnostic precision and reduced need for exploratory surgical interventions, were recognized by 90.9% of dentists with over 10 years of experience. Barriers included excessive costs (56.6%) and challenges in interpreting 3D images (37.2%). Continuous training was highlighted, with 100% of dentists with 0–5 years of experience participating in specialized courses. **Conclusions**: CBCT is valued for its superior diagnostic capabilities, but its adoption is hindered by costs and training requirements. Standardized protocols and accessible education programs are essential for wider implementation in dental practices. **Keywords:** CBCT, DENTAL RADIOLOGY, IMAGING TECHNOLOGY.

INTRODUCTION

Cone Beam Computed Tomography (CBCT) has become an essential technology in modern dental medicine, providing detailed and three-dimensional imaging of dental and maxillofacial structures. This study aims to assess the level of knowledge and attitudes of dentists regarding the use of CBCT in their daily practice.

Three-dimensional imaging through CBCT is crucial in complex clinical scenarios that require detailed visualization of

anatomical structures. It is frequently indicated for dental implant planning, assessment of bone pathology, and the diagnosis of complex endodontic lesions. Additionally, CBCT is valuable for analyzing the temporomandibular joint (TMJ), advanced orthodontic treatments, and the evaluation of dento-maxillary trauma (1, 2). Furthermore, this method is preferred for the precise localization of mandibular canals, maxillary sinuses, and other surgically critical structures (3).

CBCT provides detailed three- dimensional visualization, enabling more precise clinical planning and execution of treatments. This technology allows for superior analysis of bone structures and complex dental anatomy, improving the diagnosis of complex pathologies and reducing the risks associated with surgical interventions (4, 5). Compared to conventional computed tomography (CT), CBCT involves lower radiation doses and provides images in a shorter time frame (6). Additionally, the images can be digitally stored and analyzed, facilitating their integration into patient documentation and communication with other specialists (7).

Despite its significant advantages, the use of CBCT comes with certain limitations. The high costs associated with equipment acquisition and investigation procedures may pose a barrier for both dental practices and patients (8). Furthermore, interpreting 3D images requires specialized training, and the lack thereof can lead to diagnostic errors (5). Another disadvantage is the large file sizes generated, which may necessitate advanced computer systems for management. Moreover, although the radiation dose is lower compared to conventional CT, it remains higher than that of 2D radiographs, necessitating cautious and justified use (6, 9).

Studies conducted in recent years highlight significant variability in the level of knowledge among dentists regarding the use of CBCT. Research shows that dentists who have participated in continuous education and specialized training programs generally demonstrate a better understanding of the indications, limitations, and advantages of CBCT. For example, a study by Alamri *et al.* (2012)

(10) revealed that while most general dentists are familiar with the basic applications of CBCT, they have limited knowledge when it comes to advanced interpretation of 3D images. This underscores the importance of integrating CBCT-related education into dental school curricula and continuous professional development programs.

Another aspect explored in several studies is the confidence level of dentists in using CBCT. According to research by Pauwels *et al.* (2013) (11), specialists in oral and maxillofacial surgery or implantology exhibit the highest confidence in utilizing this technology due to their experience in interpreting three-dimensional images. However, challenges such as limited access to equipment, excessive costs, and the need for additional training remain significant barriers. Studies also emphasize that only a small percentage of dentists possess detailed knowledge of radiation protection principles associated with CBCT usage, highlighting an urgent need to enhance education in this area (11, 12). In Romania, the number of studies on this topic is extremely limited, which is why the purpose of this study was to investigate the level of knowledge and attitudes of dentists regarding the use of CBCT in dental practice, as well as to identify the factors influencing the use of CBCT

in dental clinics.

MATERIALS AND METHODS

Study design. This cross-sectional study was conducted using a structured questionnaire designed for dentists, aiming to evaluate practices and perceptions regarding the use of 2D and 3D imaging (CBCT) in dental diagnosis and treatment. The questionnaire was developed to collect data on the frequency of use of these imaging methods, their clinical applicability, perceptions of their advantages and disadvantages, as well as the dentists' level of comfort in interpreting radiological images.

The questionnaire included demographic questions (age, gender, specialty, and professional experience) and specific sections on the use of 2D radiography and CBCT, the advantages and limitations of each method, the clinical scenarios in which they are applied, and the challenges encountered. Additionally, it investigated aspects related to professional training, knowledge of radiation protection, and the factors influencing clinical decisions regarding the use of these technologies.

Participation in the study was voluntary and anonymous, open to both general dentists and specialists. Data were collected through self-administered questionnaires, completed online via the Survio platform. The questionnaire included a combination of closed-ended, multiple-choice questions and open-ended questions to allow for detailed expression of opinions. The estimated time for completing the questionnaire was 15–20 minutes.

Participant selection. This analytical cross-sectional study included a representative sample of dentists, varying in age, gender, professional experience, and geographic location. The participants were informed about the purpose of the study, and completing the online questionnaire served as informed and mandated consent, eliminating the need for a signed consent form.

Data collection. The questionnaire was designed to collect information on the frequency of use, perceptions, and experiences of dentists with radiological imaging techniques. It included questions about the demographic and professional characteristics of respondents, the frequency of 2D and 3D radiology use, and the clinical contexts where these methods are essential. Additionally, the questionnaire explored the advantages and challenges associated with these techniques, such as costs, image interpretation, and equipment access.

Another critical aspect evaluated was the respondents' competence in radiological imaging and their level of professional training, with questions about participation in training courses and the need for additional education. The questionnaire also investigated the impact of imaging on therapeutic decision-making, the reduction of exploratory surgical interventions, and the improvement of patient communication. Furthermore, topics related to workplace safety and radiation protection, including known protection methods and the risks associated with radiation exposure, were addressed.

Data collection was conducted via the completion of the questionnaire in physical or electronic format, with participation being voluntary and confidential. The varied structure of the questions, including grids, evaluation scales, and open-ended responses, allowed for detailed insights into the use of radiological imaging in dentistry. The collected results will contribute to understanding current practices

and identifying training needs in this field.

The data analysis was conducted using *SPSS version 26.0 software* (IBM, USA).

Statistical tests such as the chi-square test were employed to compare the frequencies of categorical variables, and the t-test was used to analyze differences in means. The level of statistical significance was set at $p < 0.05$, confirming the relevance of observed differences in the use of 2D radiographs and CBCT based on specialization and professional experience.

RESULTS

The data presented in first table highlight the demographic characteristics of the study sample, which consisted of 113 participants. The average age of the participants was 42.88 years, with a standard deviation (SD) of 7.22 years, indicating a moderate variation in age within the sample; the youngest participant was 30 years old, while the oldest was 57 years old. The majority of participants were women (53.1%, n = 60), while men accounted for 46.9% (n = 53). Of the participants, 55.8% (n = 63) did not indicate having a specific specialization ("no"), while 44.2% (n = 50) reported holding a specialization ("yes"). Most participants (58.4%, n = 66) had more than 10 years of experience, followed by those with 6–10 years of experience (35.4%, n = 40), while only a small percentage (6.2%, n = 7) had between 0 and 5 years of experience.

Table II highlights the use of 2D radiography and 3D imaging (CBCT) in dental practice, correlated with specialization and professional experience. Regarding the frequency of 2D radiography use, most non-specialist dentists reported daily usage (33.3%), whereas specialized dentists predominantly used this technique occasionally (88.0%). Similarly, those with limited experience (0–5 years) used 2D radiography only occasionally (100%), while dentists with 6–10 years of experience tended to use it daily (40%). In terms of CBCT usage, non-specialist dentists utilized the technology both daily (33.3%) and weekly (34.9%), whereas specialized dentists predominantly used it weekly (46.0%).

TABLE I.
Demographic characteristics of the study sample

	No.	%
Age	42.8761± 7.21745 years old (min. age 30 years, max. age 57 years)	
Gender		
Female	60	53.1
Male	53	46.9
Specialty		
No	63	55.8
Yes	50	44.2
Work experience		
0-5 years	7	6.2
6-10 years	40	35.4
> 10 years	66	58.4

The clinical situations in which 3D imaging is considered essential are diverse, with 88.0% of specialized dentists and 65.2% of those with over 10 years of experience frequently selecting the response "All of the above." Additionally, the majority of participants believe that 3D imaging reduces the need for exploratory surgical interventions, with this opinion being more prevalent among non-specialist dentists (76.2%) and those with extensive experience (78.8%). Regarding the advantages of 3D imaging, "All of the above" was the dominant response, chosen by 82.0% of

specialized dentists and 90.9% of those with over 10 years of experience. Decisions regarding the use of 2D or 3D radiology based on costs varied: specialized dentists frequently opted for more financially accessible methods (62.0%), while non-specialists (46.0%) prioritized method efficiency, regardless of cost. These trends were supported by statistically significant values ($p < 0.05$) in most comparisons.

TABLE II.

Distribution of Questionnaire Responses by Specialty and work Experience (I)

	Specialty		Work Experience		
	No	**Yes**	**0-5 years**	**6-10 years**	**> 10 years**
How often do you use 2D radiographs in your dental practice?					
Daily	33.3%	4.0%		40.0%	10.6%
Weekly	25.4%	8.0%		10.0%	24.2%
Occasionally	41.3%	88.0%	100.0%	50.0%	65.2%
p	0.000		0.001		
How often do you use 3D imaging (CBCT) in your dental practice?					
Daily	33.3%			37.5%	9.1%
Weekly	34.9%	46.0%		32.5%	48.5%
Occasionally	31.7%	54.0%	100.0%	30.0%	42.4%
p	0.000		0.000		
In which clinical situations do you consider the use of imaging essential 3D (CBCT)?					
Dental implant planning		2.0%			1.5%
Assessment of bone pathology	33.3%	10.0%		25.0%	24.2%
Treatment of complex endodontic lesions	33.3%			37.5%	9.1%
All of the above	33.3%	88.0%	100.0%	37.5%	65.2%
p	0.000		0.002		
What, in your opinion, is the main advantage of using 3D imaging (CBCT)?					
Detailed visualization of bone structures	9.5%	4.0%		20.0%	
All of the above	73.0%	82.0%	100.0%	50.0%	90.9%
Detailed visualization of bone structures + Precision in treatment planning	17.5%	14.0%		30.0%	9.1%
p	0.427		0.008		
Do you believe that the use of 3D radiology has reduced the need for exploratory surgical interventions?					
Yes	76.2%	52.0%	100.0%	37.5%	78.8%
No		40.0%		15.0%	21.2%
Not sure	23.8%	8.0%		47.5%	
p	0.000		0.000		

	Specialty		Work Experience		
	No	Yes	0-5 years	6-10 years	> 10 years
Have you attended specialized training courses on the use and interpretation of 3D imaging?					
Yes, I have attended multiple courses	11.1%	2.0%	100.0%	2.5%	
Yes, I have attended one course	46.0%	58.0%		30.0%	69.7%
No, but I plan to attend	42.9%	40.0%		67.5%	30.3%
p	0.129		0.000		
To what extent do you consider 3D imaging necessary for accurate diagnosis in dentistry?					
Essential	41.3%	18.0%		85.0%	1.5%
Useful, but not essential	58.7%	82.0%	100.0%	15.0%	98.5%
p	0.008		0.000		
How do you decide to use 2D or 3D radiology based on the associated costs?					
I always choose the most efficient method, regardless of cost	46.0%	22.0%		50.0%	30.3%
I choose the more financially accessible method for the patient	9.5%	62.0%		20.0%	43.9%
I discuss the options with the patient and decide together	44.4%	16.0%	100.0%	30.0%	25.8%
p	0.000		0.000		

Table III presents data on dentists' opinions and practices regarding the use of 2D and 3D imaging, correlated with specialization and professional experience. Most specialized dentists (57.1%) believe that the use of 2D and 3D radiology should be standardized through clear protocols, while non-specialists are more divided, with a significant proportion (34.4%) considering that the decision should remain at the discretion of the dentist. Dentists with limited experience (0–5 years) unanimously support standardization (100%), whereas those with over 10 years of experience tend to favor decision-making freedom (47.6%). The determining factors for using CBCT include the ability to visualize structures in detail, with this option being predominant among specialized dentists (89.8%) and those with 6–10 years of experience (87.5%).

Regarding communication with radiologists, most dentists report contacting them rarely, with a higher percentage among non-specialists (90.2%) and those with limited experience (100%). In cases of disagreement with a radiologist's evaluation, specialized dentists tend to rely on their own judgment (63.3%), while non-specialists prefer to request a second opinion (44.3%). Additionally, discussing CBCT with the patient is considered necessary by a majority of specialized dentists (69.4%) and those with extensive experience (88.9%). In contrast, non- specialists and less experienced dentists (0– 5 years) do not consider patient discussions mandatory, possibly indicating a lack of awareness or differing priorities. Statistically significant p-values ($p < 0.05$) support the relevance of the observed differences.

TABLE III.

Distribution of Questionnaire Responses by Specialty and Work Experience (II)

	Specialty		Work Experience		
	No	**Yes**	**0-5 years**	**6-10 years**	**> 10 years**
Do you believe that the use of 2D and 3D radiography should be standardized in dental practices?					
Yes, there should be clear protocols for the use of each imaging method	31.1%	57.1%	100.0%	32.5%	42.9%
No, dentists should have the freedom to decide based on individual cases	34.4%	42.9%		30.0%	47.6%
Only for certain specialties, such as implantology or maxillofacial surgery	34.4%			37.5%	9.5%
p	0.000		0.000		
What factors influence your decision to use 3D imaging (CBCT) instead of 2D radiographs the most?					
Case complexity	34.4%	10.2%		12.5%	33.3%
The ability to visualize structures in detail	65.6%	89.8%	100.0%	87.5%	66.7%
p	0.003		0.017		
How often, if ever, do you contact the radiologist/ dental and maxillofacial radiology specialist regarding a result?					
Rarely	90.2%	63.3%	100.0%	77.5%	76.2%
Sometimes	9.8%	36.7%		22.5%	23.8%
p	0.001		0.348		
If you disagree with the evaluation of the radiologist/ dental and maxillofacial radiology specialist, what do you do?					
I rely on my own judgment	36.1%	63.3%		65.0%	42.9%
I request another consultation from the same radiologist	44.3%	2.0%	100.0%	15.0%	23.8%
I seek a second opinion from a colleague	19.7%	34.7%		20.0%	33.3%
p	0.000		0.000		
Do you believe a prior discussion with the patient regarding CBCT is necessary?					
Yes	36.1%	69.4%			88.9%
No	63.9%	30.6%	100.0%	100.0 %	11.1%
p	0.001		0.000		

The advantages of using CBCT (Cone Beam Computed Tomography) compared to other radiological evaluation methods, are illustrated in first figure. The most significant advantages highlighted include shorter time for acquisition and interpretation (55.8%), lower radiation exposure compared to other methods (61.1%), a more useful three-dimensional structure (61.1%), and better clarity of anatomical relationships (61.1%).

Additionally, 42.5% of respondents

found the ability to analyze images on a computer beneficial. The option "All of the above" was selected by 80.5% of participants, suggesting that the majority perceive CBCT as offering a comprehensive set of benefits. Notably, no respondent considered CBCT cheaper than other methods or reported being unaware of its advantages, indicating a clear perception of this technology's superiority among the respondents.

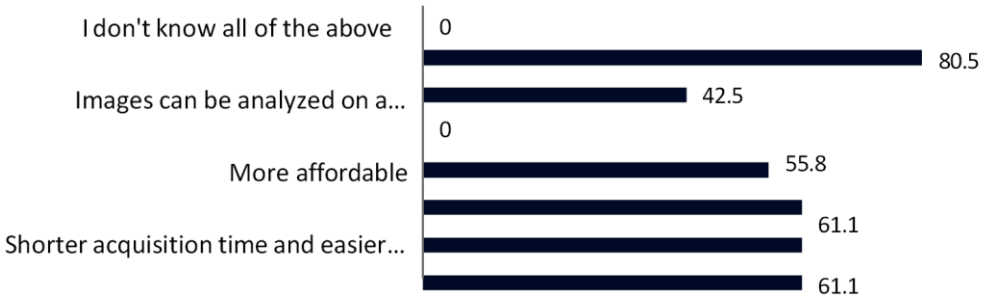

Fig. 1. The advantages of CBCT compared to other radiological evaluation methods

The main reasons why CBCT is not frequently used are presented in second figure. The most significant obstacle identified is the high procedural cost (56.6%), followed by the increased radiation risk (48.7%) and the difficulty in interpreting results (37.2%). Additionally, 27.4% of respondents consider CBCT unnecessary for the type of diagnosis they perform. Factors such as the need for specialized training (7.1%) and lack of access to this technology (7.1%) were mentioned to a lesser extent. Notably, file size and image quality were not considered obstacles, as they were not selected by any respondent.

Furthermore, 35.4% of participants chose the option "All of the above," indicating that for many users, the barriers to CBCT adoption are multiple and interconnected.

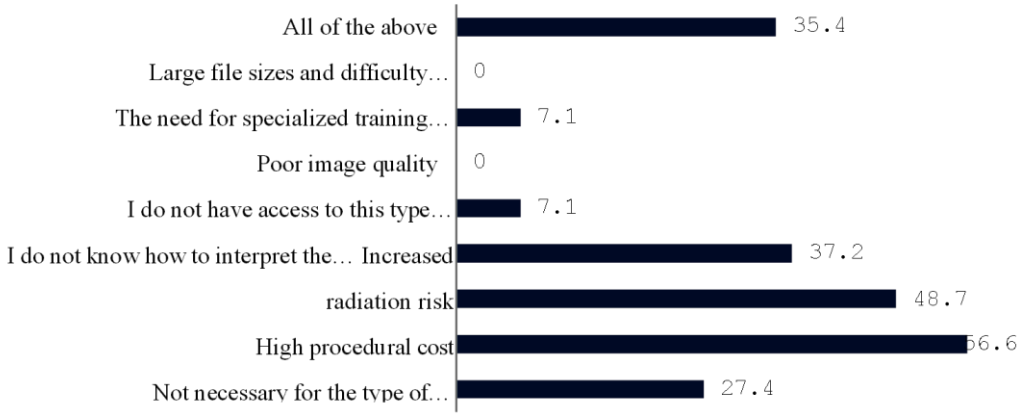

Fig. 2. Reasons for the Infrequent Use of CBCT

Figure 3 reflects users' expectations regarding the information included in a CBCT report. The most requested elements are measurements (54%) and images (54%), indicating the importance of visual and quantifiable details in data interpretation. The description of results is also considered essential (49.6%), while patient information is expected by 24.8% of respondents. The options "All of the above" and "Summary" were selected by 25.7%, suggesting that a significant number of users prefer a comprehensive and well- structured report. In contrast, differential diagnosis was not considered relevant, as it was not selected by any respondent. Other details, such as scan indication and type, were mentioned to a lesser extent (13.3%), indicating that users focus more on the imaging and analytical content of the report.

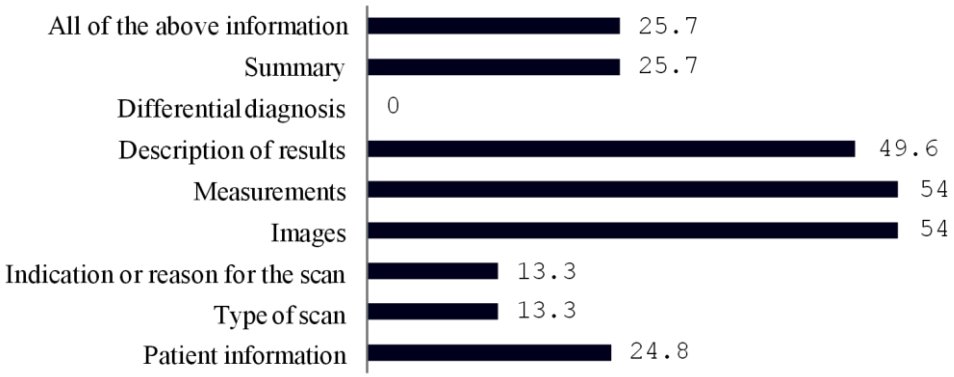

Fig. 3. Users' expectations regarding the information included in a CBCT report

DISCUSSION

Cone Beam Computed Tomography (CBCT) is recognized as a superior imaging technology compared to 2D radiographs due to its ability to provide detailed three- dimensional images of bone and dental structures.

The study results indicate that CBCT usage is more frequent among specialized dentists (46% use CBCT weekly) compared to non-specialists, where daily usage reaches 33.3%. These findings are supported by the scientific literature, which highlights the increasing adoption of CBCT in implantology, orthodontics, and oral surgery due to its enhanced diagnostic accuracy (14,15). Recent studies also emphasize that CBCT is frequently used in dental practice for the evaluation of bone pathologies and orthodontic treatment planning, aligning with the trends observed in this study.

Regarding the frequency of 2D radiograph usage, the data indicate that they are used daily by 33.3% of non-specialist dentists but by only 4% of specialists, who predominantly prefer occasional use (88%). This trend is confirmed by recent studies suggesting that 2D radiographs remain useful for routine diagnostics, whereas CBCT is preferred for complex cases requiring detailed three-dimensional information (16). On the other hand, dentists with 6–10 years of experience use 2D radiographs daily in 40% of cases, indicating a progressive adaptation to new technologies

as professional experience accumulates.

An important aspect identified in the study is the perception of CBCT advantages, with 90.9% of dentists with over 10 years of experience considering that 3D imaging offers superior benefits compared to all other available methods. These findings are supported by the scientific literature, which highlights that CBCT provides enhanced accuracy in treatment planning and reduces risks associated with surgical interventions (17). Additionally, CBCT usage has been correlated with a decrease in the need for exploratory surgical interventions, a trend also observed in this study, where 78.8% of experienced dentists reported that CBCT has significantly reduced the necessity for surgical exploration.

On the other hand, a major obstacle to CBCT adoption remains its high cost, which is perceived as a limiting factor by 56.6% of respondents. The scientific literature confirms this issue, indicating that the high price of equipment and associated scanning costs are barriers to the widespread adoption of CBCT technology (18). Nevertheless, specialized dentists tend to prioritize financial accessibility for patients (62%), whereas non-specialists (46%) prefer efficiency regardless of cost, highlighting differences in professional approaches.

The study also indicates that CBCT image interpretation is perceived as a challenge, with 37.2% of respondents considering it an obstacle. This trend is confirmed by recent literature, which suggests that the lack of specialized training can lead to difficulties in accurately interpreting three-dimensional images (19). Furthermore, studies emphasize the importance of training programs for the optimal use of CBCT, which is supported by the study results, where 100% of dentists with 0–5 years of experience reported participating in training courses.

The study findings are largely consistent with recent scientific literature, confirming the advantages of CBCT in dental diagnostics while also highlighting cost and training-related barriers. The study underscores that, although CBCT is an advanced technology, its optimal use depends on factors such as professional experience, dentist specialization, and financial accessibility.

CONCLUSIONS

The study highlights significant differences in the use of 2D radiographs and CBCT based on specialization and professional experience. Non-specialist dentists frequently use 2D radiographs, while specialists prefer 3D imaging, utilizing it more frequently on a weekly basis. CBCT is considered essential for the diagnosis and planning of complex treatments, particularly among experienced dentists, who recognize its role in reducing the need for exploratory surgical interventions.

Although cost and image interpretation challenges are perceived as barriers, most respondents acknowledge the advantages of CBCT, indicating the necessity of standardizing its use. The study emphasizes the importance of continuous professional training, revealing that dentists with limited experience actively participate in specialization courses. This suggests a growing trend in CBCT adoption in the future of dental practice.

EPIDEMIOLOGICAL ASPECTS OF SOME HEALTH CONDITIONS THAT CAN BE PREVENTED IN PEDIATRIC PATIENTS FROM REPUBLIC OF MOLDOVA (Abstract): For the assessment of the effectiveness of different health programs in recent years, population studies as well as data processing by statistical methods are used. The results of such actions in assessing the level of protection of the population against preventable contagious diseases by means of vaccination programs serve as a basis for improvement and immunization services. Evaluating the National Immunization Programs at the population level carried out in several states, allowed deciding the causes that affect poor vaccination coverage in children. In 2010, in the Republic of Moldova, actions have been taken to implement the National Immunization Program (NIP) in collaboration with UNICEF, WHO and the Global Alliance for Vaccines and Immunization (GAVI). Tenders for vaccine acquisition were organized, and 10 vaccines were purchased - rabies immunoglobulin, as well as syringes worth of 9,855,652.85 lei. At the national level, the targets of the National Immunization Program were met: vaccination against tuberculosis in children up to 1 year old, vaccination against hepatitis B in children up to the age of 1 year old, polio vaccination in children up to 1 year old, DTP revaccination in 3-year-old children, diphtheria-tetanus revaccinations in 7-year-old and 15-year-old, ROR revaccination in 7-year-old. **Keywords**: VACCINATIONS, GLOBAL ALLIANCE FOR VACCINES AND IMMUNIZATION, NATIONAL IMMUNIZATION PROGRAMMES.

For the assessment of the effectiveness of different health programs in recent years, population studies as well as data processing by means of statistical methods are used. The results of such actions in assessing the level of protection of the population against preventable contagious diseases by means of vaccination programs serve as a basis for the improvement and immunization services (1, 2). Evaluating the National Immunization Programs at the population level carried out in several states, allowed to identify the causes that explain the poor vaccination coverage in children (for example some studies conducted in the USA) (3, 4). India, Ethiopia, Bangladesh, and Cameroon

showed that the level of vaccination coverage among children aged up to 3 years old is influenced by several factors: ethnicity, living environment, migration, parents' education level, medical staff's presence in the community as well as their professional competence, the materials and the techniques of the immunization service, the family's income, government support programs, shortcomings in the organization of children censuses (4). It has been found that the vaccination coverage in India and Cameroon is influenced by the geographical areas in which these families live, as well as by the order in which children are born. In addition, these studies allow checking the official data concerning the degree to which the vaccination coverage is reported (3, 4).

In the Republic of Moldova, more than 98% of children received the BCG vaccine, the first dose of hepatitis B vaccine (HepB), DTP and polio (Polio 1), which shows the easy access of children to immunization. Vaccination coverage registered a slight decrease for the subsequent doses; thus, 94% of the children received the three recommended doses of HepB, 92% of the children received three recommended doses of the vaccine against diphtheria-tetanus-whooping cough (DTP) and 94% of the children received all the three doses of polio. 91% of the children were vaccinated against measles and 89% were vaccinated against mumps and rubella. The decline in the coverage rates reflects the percentage for vaccination abandon as follows: 6% - DTP, 4% - HepB, and 5% - polio. These numbers represent the proportion of children who received the first dose of a vaccine, but who did not get to receive the third dose, which is acceptable for the case under discussion (5).

National Immunization Program.

In 2010, in the Republic of Moldova, actions have been taken to implement the National Immunization Program (NIP) in collaboration with United Nations International Children's Emergency Fund (UNICEF), World Health Organization (WHO) and the Global Alliance for Vaccines and Immunization (GAVI). Tenders for vaccine acquisition were organized, and 10 vaccines were purchased, rabies immunoglobulin, as well as syringes worth of 9,855,652.85 lei. At the national level, the targets of the National Immunization Program were met for the vaccination against tuberculosis in children up to 1 year old - 97.9%; vaccination against hepatitis B in children up to the age of 1 year old - 96.5%; polio vaccination in children up to 1 year old - 95.0%; DTP revaccination in 3-year-old children - 95.4% (Transnistria - 82.2%); diphtheria-tetanus revaccinations in 7-year-old - 97.6% (Transnistria - 93.4%), and 15-year-old - 96.3 % (Transnistria - 79.6%); ROR revaccination in 7-year-old - 96.3% (Transnistria - 88.9%). The target of the NIP was not met for the vaccination up to 2 years of age against measles, mumps and rubella (MMR) - 74.8%, nor for the vaccination against diphtheria, tetanus and pertussis up to 1 year of age (Transnistria - 77.5%) (6). Starting from 1st November 2010 until the end of the year, 2,237 people (mostly teenage girls) were vaccinated against human papillomavirus infection with "Gardasil".

Adverse events following immunization.

The comparative analysis of the adverse events following immunization (AEFI) shows that there were 90 of such cases in 2010 (71 AEFI - 2009, and 64 AEFI - 2008). Of the total number of adverse events following immunization, there were 55 regional lymphadenitis, 8 ulcers at the injection site, and one cold abscess. After the DTP vaccine was administered, there were 16 AEFI, while after the DTP+Hib vaccine was inoculated, there were 8 AEFI. AEFI in case of DTP and DTP+Hib manifested through

hyperpyrexia, crying, agitation, seizures, fever, local reactions, all of them with a favorable evolution for the patient. Vaccination against rubella had not been done in the Republic of Moldova until 2002, when people aged between 8-29 years were immunized extensively. Data analysis on the degree of immunity against rubella demonstrated the presence of rubella antibodies in the patients' blood in 97.4% of the investigated patients. The proportion of people with minimal protective titer was only 0.3% to 6% of the children proved to be receptive to rubella (5, 6).

The immunizations administered in 2010 as well as the prophylactic and the anti-epidemic measures taken throughout the same year helped to maintain a favorable situation. There were no recorded cases of polio caused by wild virus, diphtheria, measles and rubella. Morbidity due to pertussis was kept at a low level of incidence. Of the 31 cases of pertussis, 23 were recorded in the territories on the right bank of the Dniester (including the town of Chisinau-17 cases), as well as 8 cases in the Transnistrian territory. Out of 31 cases of pertussis, 20 people (64.5%) were not vaccinated against DTP. In children, there were 2 cases of hepatitis B (1 case in 2009). Thanks to the immunizations and the measures taken against epidemics, there was a significant decrease in the incidence of mumps - 3.53% versus 7.12% in 2009. After a period of 6 years which was free from tetanus, there were 2 recorded cases of illness caused by this infection in 2010. These patients had not received complete immunization. One of them died (2, 7).

Vaccination against hepatitis.

Hepatitis viruses B, C and D have an essential epidemiological and clinical significance as over 65% of the world population lives in areas with high prevalence of infection with hepatitis B virus (HBV), and more than 2 billion people have gone through infection. (8, 9). HBV infection is the 9th mortality cause in the world and the first cause of death due to liver cancer in areas such as Southeast Asia and Sub-Saharan Africa. The estimates of the prevalence of HBV infection among the world population indicate the existence of over 360 million people with persistent infection. The trend towards persistent HBV infection is marked even and in the countries where HBV is not so spread (8). The morbidity due to acute and chronic hepatitis leads to extremely serious social and economic consequences. The economic impact caused by these diseases between 1998 and 2005 (as shown by economic damages and treatment expenses supported by the state budget following absence from work) in the country represented 266.5 million lei. Hepatitis viruses B, C and D have an essential epidemiological and clinical significance as over 65% of the world population lives in areas with high prevalence of infection with hepatitis B virus (HBV), and more than 2 billion people have gone through infection (8, 9). HBV infection is the 9th mortality cause in the world and the first cause of death due to liver cancer in areas such as Southeast Asia and Sub-Saharan Africa. The estimate of the prevalence of HBV infection in the general population indicates the existence of over 360 million people with persistent infection. The trend towards persistent HBV infection is marked even and in the countries where HBV is not so frequent (9). Population morbidity due to acute and chronic hepatitis leads to extremely serious social and economic consequences. The economic impact caused by these diseases between 1998 and 2005 (as shown by economic damages and treatment expenses supported by the state budget following absence from work) in the country repre-

sented 266.5 million lei (8, 9).

Over the last 16 years (1992-2007), the following numbers were recorded in Chisinau: 4,344 cases of hepatitis B (HBV), 1,176 cases of viral hepatitis C (HCV) and 417 cases of viral hepatitis D (HVD). Of the total number of patients with HVB, 10% of adults and 90% of children became chronic carriers (1, 7, 10). Since 2001, there has been a trend of decrease of the HVD epidemic process. For example, the incidence of morbidity in 2003 was twice lesser than in 2002 and four times lesser than in 2000-2001. The decisive factor in reducing morbidity was the HBV immunization of the population groups that were at increased epidemiological risk. In 1989, selective vaccination of newborns of HBs Ag-positive mothers was initiated and it was carried out according to the immunization schedule in autumn 1994 (1, 6). In recent years, vaccination has been possible in the case of previously unvaccinated children (birth years 1988-1993). Thus, in Chisinau, 96,885 children aged up to 19 years were subject to immunization (98.9%) in 2007. As a result, there has been a significant decrease in HBV morbidity for 0-2, 3-6 and 7-14-year-old age groups (2, 5).

The Republic of Moldova belongs to highly endemic regions, despite the achievements in the prevention of acute cases of infection with HBV. HVB is still a present-day issue in this country because of the continuous high risk of transmission, which is determined by high level of HBsAg contagiousness (8-12%) among the general population as well as the high prevalence of chronic HBV patients that are the main source of the infection transmission (5, 7). In recent years, the medical community has been increasingly focused on the HIV / HBV co-infection. Probably because of the common routes of transmission of these viruses, of the common endemic regions but also of the fact that HVB is 100 times more contagious than HIV, nearly 70% of those infected with HIV showed HBV-specific markers (1, 5). Thus, death in patients with HIV infection is often caused by a liver condition. According to statistics, hepatitis B infection is the most common cause of death in patients with HIV infection. The seriousness of the problem also results from the fact that, among the people infected with HIV, there are women with children and / or pregnant, and their number is increasing annually (2, 6). The mothers infected with HIV / HBV are certainly the main source of perinatal and habitual infection for their children not only with HIV, but also with HBV.

According to WHO data, in highly endemic regions, the main transmission way of the HBV infection is the perinatal path (70-80% of the infected children). At the same time, about 90% of these children will develop chronic HBV infection which is most likely to occur after10-15 years. According to WHO, hepatitis B represents one of the most widespread infectious pathologies in the world. About 30% of the world population has contracted the infection caused by the HBV (3, 8).

Vaccination against tuberculosis.

In the Republic of Moldova, morbidity and mortality have increased since 2001. In 1993, WHO declared that TB represented an exceptional global situation and took immediate action to avoid the spread of this disease. A high level of illness due to tuberculosis was recorded in Moldova in the late 1990s when economic problems had a negative impact on all areas, medicine included (4, 11, 12).

The funding allocated to the health system plummeted, drugs were scarce and the control of the early diagnosis of diseases was neglected. In this context, the epidemiological analysis became the main way

of developing effective measures in fighting tuberculosis. On an international level, recurrent disease has been noticed, which is due to the demographic explosion, the deterioration of the health of the population in many areas of the globe, the increasing number of homeless people, the people who refuse vaccination and the growing number of immigrants from countries where tuberculosis is endemic (1, 3, 13). Two things contribute to all this: the HIV / AIDS pandemic, which is considered the most important factor that favors tuberculosis and the appearance of tuberculous bacilli which are tuberculostatic resistant. A study conducted by the World Health Organization states that there is a new type of tuberculosis which is spreading in the world and which is highly resistant to drugs, especially in the countries of Eastern Europe, Africa and China (8, 9, 10). The data collected from 81 countries between 2002 and 2006 showed that the new XDR-TB strain, found in 45 countries, is incurable. About 500,000 people worldwide are infected with this form of the disease, which kills around 30% of patients. Most cases of patients with the new form of tuberculosis were diagnosed in Moldova, Azerbaijan, Russia, Ukraine and Uzbekistan (2, 9). Annually, tuberculosis cases in women are increasing and infant morbidity remains at a high level. We are facing multidrug-resistant tuberculosis (from 3 cases in 2001 to 229 cases in 2006). In 2007, 194 patients were diagnosed with tuberculosis, of which 48 patients died. An alarming increase in infant morbidity occurred between 2003 and 2007. What is also alarming is the rise in the number of new cases of MDR TB. Of the total number of patients (46) in the city of Chisinau, 38 (82.6%) were isoniazid resistant, 38 (82.6%) were streptomycin resistant, 32 (69.6%) were rifampicin resistant and 26 (56.5%) were ethambutol resistant. The number of MDR patients was approximately equal in rural areas and in urban areas. Similarly, the number of single-drug resistant patients was almost equal to that of multidrug resistant patients. The rate of morbidity by gender reveals that 27.5% are female patients and 72.5% are male patients. General morbidity of tuberculosis remains high in young pediatric patients and young adults (0-26 years) (2, 5, 6).

Vaccination against mumps.

Mumps represents another important issue for the Republic of Moldova. A study conducted in Chisinau, including 165 patients who had been diagnosed with mumps and hospitalized in various hospitals in the city, reveals that 31% of the patients received the vaccine against mumps in March-April 2008, and the rest did not. The epidemiological investigation shows that 76% of the patients came from areas with outbreaks of mumps-communities (kindergartens, schools, colleges, work). Of the 165 patients, children and adolescents represent 46.7%, while the 20-34 age group represents 53.3%. It has been found that males (73.9%) are more affected than females (26.1%), both in children and adolescents and in young adults. Most patients (89.7%) were hospitalized during the first week of disease, of which 77.7% were admitted to hospital within the first 3 days. Mumps meningitis was diagnosed only in children (2.4%). The mild form of mumps was encountered in 38.8% of patients; the average form was present in 43%, while the severe form appeared in 18.2% (children and young adults with the same frequency). The disease evolved in 97% of cases with parotid gland damage (1, 2, 10).

Following the latest epidemic of mumps in the city of Ungheni, which took place between during 1995-1997 and was due to the small number of immunized people (less than 70% in 1994-1999), the morbidi-

ty due to this disease has shown a downward trend. Reduced morbidity was due to vaccination against mumps (from 90% in 2000 to 97% in 2007), to the implementation of the trivalent vaccine against measles, mumps, rubella (ROR) in 2002, with the two doses at the ages of 12 months and 7 years, respectively. The incidence of mumps was at the average annual level in the country and did not exceed 10 to 15%; it also showed a downward trend, and in 2006 there were only 9 cases of disease. The retrospective analysis of 939 cases of mumps recorded in the district of Ungheni in October 2007-March 2008 showed the following: at the end of March 2008, 52 localities of the district were affected (72.2% of the territory). The distribution of the disease cases by area of origin showed a predominance of the disease in the rural areas 65.7% (617 cases) compared to 322 cases (34.3%) in the urban areas. Most cases of mumps were recorded in pre-university institutions (high school, middle school, kindergarten), mainly in large classes-605 cases (65%) of total number of patients.

The mumps epidemic affected people aged from 1 to 53 years old (3, 6). The average affected age was 16 years. 67.2% of the patients (631 cases) belonged to age group 14-18, and 11.0% (116 cases) belonged to the age group 10-13. The other age groups had little epidemiological significance.

The time interval between the time of immunization and the appearance of the clinical signs of disease had an average value of 13 years, with a minimum time interval of up to 1 year (2 people) and a maximum one of 28 years (1 person). The percentage of sick people who had not received any dose of vaccine against mumps was 14.3% (134 cases). The patients who had been immunized with a single dose of vaccine represented 76% (714 cases), while the patients who had been revaccinated represented 5.2% (49 cases). Most of the infected people who had not received any doses of the vaccine belong to the age group 15-19 (58%), which also includes the patients who had received a single dose of vaccine. Most revaccinated patients belong to the age group 10-14 and make up for over 85% of this group. In terms of the gravity of the clinical picture, mumps cases were distributed as follows: mild cases-235 (25.0%), medium cases-635 (67.6%) and serious cases-69 (7.3%) (1, 3).

The assessment of the knowledge regarding the vaccines has been done by means of questionnaires. For the study, a specific questionnaire with five questions has been especially designed for middle school and high school pupils (grades 7 - 12) in the city of Calarasi, Republic of Moldova (1, 5). Of the total of nearly 300 students, 180 answered the question “What is vaccination?” by saying that it was “a process for protecting the body against infectious diseases”. The others answered that vaccination was “a drug” or “an injection for treating diseases”. The proportion of pertinent responses on the role and benefits of vaccines is satisfactory. However, about 10-15% of respondents indicated other answers: that vaccination was necessary “to be healthy”, “not to catch a cold”, “not to catch a venereal disease”.

It can clearly be noticed that adolescents know too little about the differences between non-transmissible and transmissible diseases. For the question “List the diseases against which vaccines are used”, all the respondents (100%) correctly listed from one to three vaccine-preventable diseases. Tuberculosis was most often indicated (90% of respondents), as well as hepatitis (82.2%), influenza and diphtheria (57.5%); up to 43.1% indicated measles and mumps. When asked to indicate the

place where they received the last dose of vaccine, all the respondents answered that they had received it in medical institutions in the locality where they live. The small number of adolescents who know the name of the last dose of vaccine they received shows their lack of interest in their own health, leaving the medical personnel and / or family to worry about this (10).

CONCLUSIONS

The efficiency of the immunization programs largely depends on the population participation in their implementation. It is important what teenagers and young adults or future parents think about vaccines and vaccination as a preventive measure against some transmissible diseases.

It is necessary to increase personal responsibility of everyone to their own health and it is appropriate for the medical personnel of schools as well as teachers to get involved in the process of training for a healthy life.

OPEN APPROACH VERSUS MINIMALLY APPROACH FOR THE TREATMENT OF VARICOCELE IN CHILDREN-AN EPIDEMIOLOGICAL STUDY **(**Abstract**).** **Aim**: The therapeutic indication of varicocele and the best method of treatment in children are still subjects of extensive debate in the literature. The purpose of the present study is to compare two of the most frequently used methods of treatment, both in terms of patient evolution and in economic terms. **Material and methods:** The observation charts of 69 patients with varicocele, who were hospitalized in the Pediatric Surgery Clinic of the "Saint Mary" Children's Emergency Hospital, have retrospectively been analyzed for a period of approximately 4 years. Three groups of patients have been created depending on the method of treatment - 25 cases operated by laparoscopic approach, 28 cases where the classical approach was used and 12 cases where surgery was denied or delayed. The demographic data, the duration of the surgery, the duration and the cost of hospitalization, the complications and the relapse rate have been compared statistically. **Results and discussion**: Patients mainly came from rural areas (73.8%), with an average age of approximately 14.5 years. The difference in weight of 54.7 / 53.5 kg between the group treated classically and the group treated laparoscopically was insignificant (p=0.76). The total duration of hospitalization and the postoperative duration of hospitalization were slightly higher in the group treated laparoscopically (5.24 / 4.28 days and 2.08 / 1.82, respectively), but the differences were not statistically significant (p=0.13 and 0.29, respectively); yet, the duration of the surgery was significantly higher (p=0.002) in the group treated laparoscopically (73.0 / 57.32 minutes). In terms of relapse, the postoperative progress was comparatively similar - only one patient in both groups relapsed and then was addressed by the other technique. However, regarding the rate of the postoperative occurrence of the hydrocele - a well-known complication following the surgical treatment of varicocele - it has not occurred in any patient treated classically, but it occurred in four patients treated laparoscopically (16%). Both the overall hospitalization costs (1,818/1,999 RON - classical / laparoscopic approach) and the costs divided on medication, sanitary materials used and medical tests were similar. **Conclusions:** The treatment of varicocele by laparoscopic approach began to be practiced in our clinic about four years ago, and although it is still being perfected (long duration of surgery and long duration of hospitalization), the results are encouraging. **Keywords:** CHILD, VARICOCELE, LAPAROSCOPY, CLASSICAL APPROACH.

A varicocele is the most frequent prepubertal andrological pathology which can cause infertility. This condition has been known since the first century, when it was described by Cornelius Celsus as follows: "when the disease has spread over the testicle and its cord, the testicle sinks a little lower, and becomes smaller than its fellow, in as much as its nutrition has become defective" (1). In 1550, Ambroise Pare described varicocele as "a pack of blood vessels well filled with melancholic blood" and, in 1885, Barwell described its surgical treatment, which is the subcutaneous ligation of the spermatic vessels (2). In 1948, Palomo described the retroperitoneal approach for the ligation of the spermatic veins at the inguinal canal exit, with the preservation of the spermatic artery (3). The incidence of varicocele is less than 1% in prepubertal boys, 15-30% in children of 12-18 years of age (4) and approximately 15% in the adult male population. A varicocele may be primitive (idiopathic, essential), as it is usually the one on the left side, which appears after puberty (13-30 years) without a determined cause, and secondary, which occurs due to a condition that produces a barrier to blood flow in the spermatic veins (e.g. right renal carcinoma). Another cause of secondary varicocele is the "nutcracker" syndrome, which is the left renal vein compression by the superior mesenteric artery, and the venous drainage obstruction and stasis at the pampiniform plexus (5). Varicocele may be bilateral in up to 2.5% of cases in adolescents and in up to 10% of cases in adults after the age of 35 - 40 (6). In 95-98% of cases, the condition occurs on the left side in adolescents and, if left untreated, it is the one that causes male infertility in 15-40% of infertile adults (6). Primitive varicocele is favored by several existing anatomical features on the left side, namely: the left spermatic vein is 8-10 cm longer than the right one; the blood flow angle of the left spermatic vein into the left renal vein is a right angle (90 degrees), which favors venous stasis; the colon compresses the left spermatic vein; the left spermatic artery spirals around the vein. The risk factors are: prolonged standing, poor quality of the venous wall, absence of valves inside the veins, hereditary constitutional predisposition and a genetic component, increased abdominal pressure. The pathophysiologic mechanism responsible for the infertility associated with varicocele is not fully elucidated; in addition to certain genetic and molecular causes, many other causes can be mentioned: testicular hypo perfusion and associated hypoxia, oxidative stress, increased temperature, reflux of certain toxic metabolites in the adrenal gland or in the kidneys, hormonal imbalance and toxic exogenous factors (7). Regarding the therapeutic indication of varicocele or the best surgical approach, there are still many controversies in the literature when it comes to children and adolescents. The purpose of the present study is to compare two of the most common methods of treatment, both in terms of patient outcome and in economic terms.

MATERIAL AND METHODS

We conducted a retrospective analytical study on 69 children hospitalized and treated in the Pediatric Surgery Department of the "Sf. Maria" Emergency Children's Hospital of Iaşi, between January 2013 and September 2016. The patients were identified per the disease code entered in the hospital's computerized database, and then the patients' records were extracted from

the hospital archives. 4 patients were excluded from the study for missing data. Demographics, associated disorders, investigations, duration of surgery, duration and cost of hospitalization, complications and relapse rate were statistically compared. Three groups of patients have been created depending on the method of treatment - 25 cases (38.4%) operated by laparoscopic approach, 28 cases (43.0%) where the classical approach was used and 12 cases (18.4%) where surgery was denied or delayed. The data were processed by using the specialized Microsoft Excel data analysis and processing module.

RESULTS

Patients mainly came from rural areas (73.8%), with an average age of approximately 14.5 years (between 8 and 19 years of age). The reason why they went to the doctor was the appearance of a swelling in the scrotum, accompanied by local sensation of heaviness; in 40% of cases, persistent pain was the main symptom. The surgical indication was established on the following criteria: at least clinical second grade varicocele, smaller ipsilateral testis with ultrasound-measured volume and / or persistence of symptoms for more than three months. The decision to intervene surgically and the method of treatment (classically or by using a minimally invasive approach) depended on the doctor's option and experience. For surgeons who are familiar with both methods of treatment, the patient's weight was the one that mattered in the choice of surgical approach. Thus, 18.5% of patients were treated conservatively, 43% were operated on classically and 38.5% of patients were treated by laparoscopic approach.

The difference in weight of 54.7 / 53.5 kg between the group treated classically and the group treated laparoscopically was insignificant (p=0.76). Of the 65 patients, 4 patients (6.1%) had a varicocele on the right, 1 patient (1.5%) had a bilateral varicocele and the rest had a varicocele on the left. 27 children (41.5%) had other associated diseases, which were not related to the disease studied. In terms of imaging tests, 22 of the 28 cases (78.5%) of varicocele treated classically were confirmed by scrotal ultrasound - this investigation highlighted the smaller size of the left testicle as compared to the right one in 11 cases (50.0%); in 19 patients (67.8%), the abdominal ultrasound was also used - this was normal in all cases except for one patient for whom the investigation revealed the presence of bladder stones. For one patient, CT was used due to significant weight loss over the past six months; however, it did not reveal associated abdominal pathology. In the group of patients who were treated laparoscopically, 23 of the 25 patients (92.0%) were also diagnosed by scrotal ultrasound; in 7 patients (30.4%), the affected testicle was smaller than the contralateral one. Of the 25 patients, 23 (92.0%) also underwent abdominal ultrasound, which was normal; one patient with grade III left hydronephrosis and enuresis underwent abdominal CT and one patient with a history of right varicocele and right orhiepididymitis also underwent abdominal MRI.

Of the 12 patients (18.4%) who were not approached surgically, only one patient had grade III varicocele and he refused the surgery; 8 patients were diagnosed with grade I varicocele, and two of them were scheduled for surgery; three patients with subclinical varicocele and six patients with grade I varicocele were proposed long-term

follow-up care. All the patients in this group underwent abdominal ultrasound, which turned out to be normal, and scrotal ultrasound, which showed that one testicle, the affected one, was smaller in 3 patients (25%): one patient who refused the surgery and two patients who were scheduled for surgery.

The total duration of hospitalization (including controls) and the postoperative duration of hospitalization were slightly higher in the group treated laparoscopically (5.2 / 4.3 days and 2.1 / 1.8, respectively), but the differences were not statistically significant (p=0.13 and 0.29, respectively); yet, the duration of the surgery was significantly higher (p=0.002) in the group treated laparoscopically (73.0 / 57.3 minutes). In terms of relapse, the postoperative progress was comparatively similar - only one patient in each group relapsed (4% and 3.5%, respectively) and then was addressed by the other technique. One patient in each group showed postoperative signs of orhiepididymitis in the affected testicle; the patient treated classically was subsequently diagnosed with varicocele recurrence. However, regarding the rate of postoperative occurrence of the hydrocele - a well-known complication following the surgical treatment of varicocele - it appeared on average at 6 months postoperatively in only one patient treated classically (3.5%) and in four of the patients treated laparoscopically (16%) - overall, the postoperative hydrocele rate is 9.4%. In two patients (one in the group treated laparoscopically and one in the group treated classically), the small size of hydrocele was the indication for conservative treatment. One patient was treated by puncture aspiration of hydrocele with favorable results; the other two patients, in whose case the fluid reappeared after having been aspirated, required surgical intervention, i.e. Jaboulay-type hydrocelectomy. Of the 25 patients (38.4%) who were approached laparoscopically, three also received concomitant treatment for other associated diseases-i.e. umbilical hernia in one patient and inguinal hernia in two other patients.

From an economic point of view, both the overall hospitalization costs (1,818/ 1,999 RON, p=0.49 - classical / laparoscopic approach) and the costs divided on medication, sanitary materials used and medical tests were similar. Thus, for the group treated classically, the money was spent as follows: approximately 92 RON on medication, 89 RON on sanitary materials and 62 RON on medical tests, compared to 111 RON (p=0.57), 135 RON (p=0.23) and 86 RON (p=0.32), respectively, in the group treated by minimally invasive approach.

DISCUSSION

A varicocele is a condition that most often (95-98%) occurs on the left side in adolescents; it can be bilateral in up 2.5% of cases in adolescents and in up to 10% of cases in adults (6). In our group of adolescents, the condition was identified on the left side in 93.9% of cases and was bilateral in 1.5% of patients. Varicocele symptoms can be discreet, such as: heaviness in the scrotum, testicular discomfort to continuous pain, difference in size between the two testicles, psychosexual disorders if the pain is persistent. All the patients in our study sought medical attention for swelling with or without heaviness in the scrotum, and almost half of them complained of persistent pain. Quite often, varicocele is asymptomatic and is discovered during routine ultrasounds or during investigations

for infertility in adult couples. Physical effort, exposure to heat and prolonged standing favor the onset of varicocele and can explain the prevalence of the disease in patients from rural areas (73.8%), where children and adolescents are much more physically active and sometimes start work at an early age. The objective physical examination of the patient highlights the increased size of the hemiscrotum; the affected spermatic veins can be visibly dilated, making a specific pattern in the thin scrotal skin. On palpation, this conglomeration of veins is painless and feels soft, mobile, like a "bag of worms". Three clinical grades of varicocele are described by Dubin and Amelar (8): Grade 1 - the varicocele is palpable only during special maneuvers that increase abdominal pressure (Valsalva maneuver); Grade 2 - it is palpable in dorsal decubitus, without other maneuvers; Grade 3 - this type of varicocele is both palpable and visible (the veins are dilated more than 4 mm) and it can be identified by the patient (this degree, but not only this one, is associated with patient's impaired fertility).

Of the radio-imagistic investigations, the scrotal Doppler ultrasound is commonly used to record the spontaneous blood flow speed in the spermatic veins, which usually indicates stagnation of blood in the varicose, dilated veins. Normally, the size of the veins of the pampiniform plexus range from 0.5 to 1.5 mm in diameter; if the dilation of these veins is greater than 2 mm, it suggests the diagnosis of varicocele (9). Testicular ultrasound can also confirm the gonadal hypotrophy, as it happened in 50% and, respectively, 30.4% of our cases; it can also confirm the subclinical varicocele, which is the dilatation of spermatic veins that can be detected only by ultrasound, and cannot be clinically evidenced, not even through the Valsalva maneuver; it is estimated that approximately 25% of patients with varicocele on one side and which can be detected during a clinical examination have subclinical varicocele on the other side (10). Retrograde spermatic phlebography (venography) can be considered the "gold standard" for the diagnosis of varicocele, but just like scintigraphy, it has limited indications due to invasiveness and is used primarily for relapses (11); contact thermography is of historical interest; investigations such as CT or MRI are indicated in the diagnosis of recurrent or secondary varicocele; the spermiogram - a predictive test for an adult patient's ability of fertilization, will be performed before and after the surgery; the spermiogram is usually affected: lower sperm count, with poor mobility. Since our group was made up only of patients of pediatric age, the spermiogram was not carried out for ethical reasons.

The evolution of varicocele is extremely slow. The condition causes discomfort locally and may lead to complications in adults, such as changes in spermatogenesis and infertility because, due to the blood that stagnates in the testicular veins, the local temperature increases and spermatogenesis is affected (both the quality and the quantity of sperm decrease). Therefore, if left untreated, a varicocele can lead to the atrophy of the affected testicle, to lower testosterone levels and, eventually, to infertility (9,10). But since not all adults with varicocele are infertile, the decision to treat a child or an adolescent suffering from varicocele only to prevent possible subsequent infertility is controversial. Unfortunately, in the case of children, there is no agreement on the therapeutic indication of

varicocele and neither on the best surgical approach; the goal of the treatment is the prevention of the testicular function degradation and the gonadal atrophy, as well as the prevention of infertility, but with a low rate of recurrence and appearance of a secondary hydrocele, of nerve injuries or of other complications. The American Society for Reproductive Medicine recommends the treatment of varicocele in adults when it is palpable and at least one of the sperm analysis parameters is abnormal, in case of infertile couples where the woman is normal. In adolescents, the same organization considers that only the patients with varicocele and hypotrophy of the affected testicle should be eligible for surgery (11). Other therapeutic indications in adolescents are: clinical grade 2 or 3 varicocele, testicular discomfort, abnormal semen analysis and venous reflux detected by ultrasound; however, these indications are not universally accepted (4, 8). In our case, the criteria for recommendation of surgical treatment were: at least clinical grade 2 varicocele, smaller ipsilateral testicle measured by ultrasound and / or persistence of symptoms for more than three months (40% of children came in with persistent scrotal pain). There are studies demonstrating the beneficial effect of varicocelectomy in adolescents on the testicular growth, on the normalization of testosterone levels as well as on the improvement of sperm quality. Therefore, the decision to intervene surgically in a teenager with varicocele is left at the discretion of the physician (5,7).

Despite the well-known natural history of varicocele, the optimal method of treatment is still a controversial subject in the literature. There are two main types of treatment for varicocele: varicose vein ligation and sectioning by using a classical or a laparoscopic approach and selective trans venous embolization or varicose vein sclerotization by means of interventional radiology procedures (5); in case of recurrence after one method, the alternative technique may be used. The sectioning of the spermatic veins can be done classically by retroperitoneal surgical approach (Palomo technique), inguinal (Ivanissevich technique), microsurgical (inguinal or subinguinal) (6) or by laparoscopic approach. There are studies that show that the lowest rate of recurrence and complications can be obtained through the microsurgical subinguinal approach, but the technique is more difficult (7). Over the last 20 years, the embolization or the sclerotizing of testicular veins by percutaneous inguinal approach under local anesthesia has had results in terms of fertility that are like the advantage of minimal invasiveness and a low risk of developing postoperative hydrocele (8). Techniques such as NOTES (natural orifice transluminal endoscopic surgical procedures) and LESS (laparo-endoscopic single-site), as well as the robotic-assisted inguinal approach are also attractive, but their role in the treatment of varicocele must be validated through randomized studies, on large groups of patients.

A recent study analyzes the methods of diagnosis, the indications and the treatment alternatives of varicocele in children and adolescents, based on the responses of 131 pediatric urologists (4, 10,11). Comparing the results of this study with our results, we can say that: the decision of surgical treatment is based on the reduced size of the affected testicle (96% of cases), testicular pain (79%), abnormal parameters of the semen analysis (39%), while our decision was based on the clinical grade of varico-

cele, the testicular shrinkage determined by ultrasound and / or the persistence of painful symptoms for more than three months (40% of cases); the average age at the time of surgery was 12.5 years compared to 14.5 years in our study; the preferred method of treatment was the laparoscopic approach (38% of surgeons), followed by the microsurgical sub inguinal approach (28%), the inguinal approach (14%) and the retroperitoneal approach (13%), compared to 38.5% - laparoscopic approach in our case and 43% - retroperitoneal approach (note: the inguinal or the sub inguinal approach is not practiced in our clinic).

The laparoscopic Palomo technique has been the preferred technique for the treatment of the varicocele in children in many pediatric surgery centers since 1988 (4, 9). Laparoscopy has numerous advantages: the patient recovers fast, the surgeon can see the place very well during the surgery, the dilated veins can easily be located, the relapse rate is lower, and there is the possibility to incidentally diagnose and treat possible associated pathologies - three of our patients had their umbilical hernia and inguinal hernia treated during the same surgery. Surgery usually takes less than one hour and the patient requires hospitalization for 24-48 hours postoperatively; these aspects have been confirmed by our study. Thus, in the study presented, the average duration of the surgery was less than one hour for the classical approach and just over one hour for the laparoscopic approach; the latter was calculated by also taking into consideration the three cases that involved complementary surgical procedures for the treatment of associated diseases, which increased the duration of the surgery. Besides the duration of the laparoscopic approach, which was longer, the two surgical techniques proved to be similar in terms of efficacy and cost; here, one must consider the fact that the laparoscopic approach was introduced in our clinic only about four years ago, which means that our pediatric surgeons are still learning in this regard. We expect the future duration of the laparoscopic approach to decrease gradually, as well as the length of postoperative hospitalization (from two days to one day), which will translate into lower hospitalization costs. Thus, the laparoscopic approach will become option number one in our clinic.

Some surgeons perform the mass ligature and sectioning of the spermatic artery and veins as part of the classical approach as well as the laparoscopic approach. There is no evidence that this technique adversely influences further development, since the testicle will still receive arterial blood from the collaterals of the deferential artery. Although the topic is controversial, a comparative study conducted on 122 adolescents who were operated on laparoscopically, with and without protection of the spermatic artery during varicocelectomy, showed significant improvement in semen quality in patients who had their spermatic artery protected (4). Moreover, the protection of lymphatic vessels during varicocelectomy could decrease the rate of postoperative hydrocele (2, 10). The effect of the surgery (the reduction of testicular varicose veins and the improvement of the spermiogram) is visible after two or three months. The relapse rate can reach 20%. In our study, the mass ligature and sectioning of the spermatic artery and veins was performed, regardless of the chosen method of treatment; only one patient in each group relapsed (3.5% and 4%), but this figures can also be the result of an error due to patients' follow-up for a short

period - in the long term, more relapses may occur - or to the fact that patients with a relapse addressed other centers of pediatric surgery. Other possible postoperative complications are: occurrence of testicular hydrocele, permatic artery injury with subsequent testicular atrophy, bleeding and infection. In our study, postoperative hydrocele occurrence rate was 3.5% for the classical approach and 16% for the laparoscopic approach, compared with the rates reported by other studies: 13% and 20%, respectively (2, 11). The reason for the hydrocele occurrence was probably the mass ligature of veins with lymphatic vessels, both in the classical approach and in the laparoscopic one.

CONCLUSIONS

This study found that, since not all adults with varicocele are infertile, it is obvious that not all adolescents with this condition must be operated on. Yet, the criteria regarding *which*, *when* and *how* adolescents with varicocele should be treated have not been clearly defined yet. For children, especially, further studies are needed to formulate clear treatment protocols for this condition. The treatment of varicocele through laparoscopic approach has been practiced in our clinic for about four years, and although it is still being perfected (long duration of surgery and long duration of hospitalization), the results are encouraging.

THE STUDY OF THE ASSOCIATION OF DECAY RISK WITH MALOCCLUSIONS IN MIXED DENTITION AT CHILDREN FROM NORTHEAST ROMANIA. A TRANSVERSAL RETROSPECTIVE STUDY (Abstract): **Aim**. The purpose of this study was to investigate if high values of DMFT/dmft indices constitute risk factors for installation in various types of malocclusions in mixed dentition. **Material and Methods** The study consisted of 600 study-cast with mixed dentitions coming from the children in northeastern Romania. WHO (World Health Organization) dental caries criteria were applied to both groups. The existence of an increased caries risk was deducted from the dmft (decay, missed, filled temporary teeth) and DMFT (Decay, Missed, Filled Teeth) indices related to age. Malocclusion was classified in the three planes in accordance with the major symptom. The statistical study was conducted in SPSS 16.0 for Windows. The risk factors we have identified through calculating the odds ratio and relative risk. **Results:** Mean value dmft/DMFT (index in mixed dentition was found 3.64±2.686. The highest values of the dmft/DMFT indices were found in patients with normal overjet (4.73± 2.892) and normal overbite (4.04±2.781). In the transverse plane, the lowest value of DMFT/dmft index was recorded in patients with spacing (2.63±1.915), and the highest values were observed in patients with the combined diagnosis of crowding and lateral cross bite (4.97±3.010) respectively of crowding and spacing (4.65 ±2.792).The presence of malocclusions in the three plans is not influenced by increased DMFT/dmft index (DMFT/dmft>5) unless combined diagnoses of crowding and lateral cross bite, and crowding and spacing where the relative risks are over 2.5. **Conclusions**: The present study concluded that the prevalence of dental caries in children with mixed dentition is higher in patients with normal overjet and overbite. In terms of the risk of developing a certain malocclusion with dental crowding associate with lateral cross bite, respectively dental crowding associate false spacing are present under a high caries activities. **Keywords:** DENTAL CARIES, INDEX DMFT/DMFT, MALOCCLUSIONS, MIXED DENTITION, RISK FACTORS.

Dental decay remains a major public health problem, its management still requires a great deal of the budget provided for healthcare, which is the reason why it still requires continued efforts to find solutions to prevent this disease (1-3). Just as with other chronic diseases with high prevalence in the population, the actual inci-

dence and prevalence data (60-75% for deciduous teeth and 20-40% for permanent teeth at children with mixed dentition) for dental decay were obtained through epidemiological studies (4-11).

In previous attempts to investigate a possible association between dental decay and malocclusions, studies have shown conflicting or inconclusive results (9-11). While some authors have reported a positive association between dental decay and malocclusions (12-20), others could not establish any significant relation (9).

Furthermore, the controversial results were obtained in studies that found a possible relation between malocclusions and various oral hygiene indices (12, 13). The presence of a positive association between malocclusions and periodontal health has been described by Gabris (13).

However, few studies have evaluated the dental and orthodontic statuses simultaneously in an appropriate manner and examined less the possible interactions between them, in terms of dental decay risk. It was only assumed by many authors the hypothesis that dental decay and premature loss of temporary teeth are factors that predispose to malocclusions in mixed and permanent dentition (21). However, a causal relation between dental decay and malocclusions has not been demonstrated with certainty, until now. Clarifying the role of dental decay in the further development of malocclusions can assist in the clinical decision, in setting the priorities in public treatment.

This study's objectives represent the answers to the following questions: 1. Is dental decay in mixed dentition more common in some types of malocclusions? 2. Is the dental decay risk, represented by high values of the DMFT/dmft (Decay, Missed, Filled Teeth) index in mixed dentition, a risk factor for installing certain types of malocclusions?.

In this regard, our study aims to investigate the dental decay risk for the occurrence of malocclusions, calculating the DMFT/dmft indices for mixed dentition in a group of children with malocclusions, from northeastern Romania.

MATERIAL AND METHODS

This transversal retrospective study comprises the random selection of 600 subjects between the ages of 6 and 8 years old, based on documents and medical information (observation sheets, orthopantomography's, intra/extra-oral photographs and study-casts) that have been retrieved from the archives of the Pediatric Dentistry Clinic from Iasi (Romania) and were subsequently analyzed. The selection condition was the permanent first molars and incisors to be erupted (dental age of 8 years old) as well as no orthodontic treatment before the examination. The ethical committee's approval for this study was not necessary because it is a retrospective archive study. As usual protocol, all patients (their parents) sign the informed consent that they agree for patient (children) data to be used in scientific studies. Data were collected by a single examiner, who prior did training and calibration exercises.

The registration criteria of dental decay experience were carried out per WHO (World Health Organization) guidelines using the dmft index for deciduous teeth and the DMFT index for permanent teeth, on both study-casts and intraoral photographs. The premature loss of temporary teeth due to dental decay was considered to exist, when were absent from the dental arch 2 years before the normal exfoliation

and the eruption of the permanent successor tooth.

The increased dental decay risk was assessed per German guides for young teeth (tab. I) (22). These defined the individual dental decay risk of a child, per dmft respectively, DMFT indices, at the child's age. The 1-4 criteria were used for children with primary dentition and the criteria 4-5 for children with mixed dentition. In the present study, we considered an increased dental decay risk, when the index dmft/DMFT>5.

TABLE I
The increased dental decay risk per German guides for young teeth (22)

1	Up to 3 years	Dental decays, dmft>0
2	Up to 4 years	dmft>2
3	Up to 5 years	dmft>4
4	Up to 6-7 years	dmft, DMFT>5 or D/T>0
5	Up to 8-9 years	dmft, DMFT>7 or D/T>2
6	Up to 10-12 years	DMFS>0

The occlusion examination was carried out on study-casts set in static occlusion. All the irregularities in the sagittal, transverse and vertical planes were recorded. According to the extent and prognosis of the orthodontic treatment, the malocclusions were analyzed in all three planes, consistent with the major symptom: in the sagittal plane - normal overjet, class II / 1 incisive malocclusion (increased overjet) class II / 2 incisive malocclusion (retroclined maxillary incisors with minimal or reduced overjet), class III incisive malocclusion (anterior cross bite with or without mandibular overjet); in the vertical plane - normal overbite, anterior open bite, deep bite; in the transverse plane – single tooth cross bite/lateral cross bite, crowding, dental spacing, or associations between them.

The statistical study was conducted in SPSS 16.0 for Windows. We determined the frequency distributions and we determined the elements of descriptive statistics for the numerical parameters: mean value, mean standard error (MSE), standard deviation (SD), minimum and maximum values. We used the *t* test and the Mann-Whitney nonparametric test (U) for independent samples of the comparative study between the groups for numerical variables, having previously checked the hypothesis that variables abide the normal law using the Kolmogorov – Smirnov fitting test. The level of significance $p<0.05$ was considered statistically significant, and the relative risks over 1.5 were considered important. To identify statistically significant differences between qualitative variables, we used the method of contingency tables and the chi-square test, furthermore we have identified the risk factors by calculating the odds ratio (OR) and the relative risks. Intra-examiner agreement was assessed using Kappa coefficients, which were 0.82 for malocclusions and 0.80 for tooth decay.

RESULTS

a. Frequencies by gender, area of origin and anomalies of the study group. Of the 600 analyzed subjects, 291 (48.5%, average age of 7.31±0.6) were females and 309 were males (51.5%, average age of 7.45 ± 0.8) (fig. 1), 318 (53%, average age 7.41 ± 0.55) were from urban areas and 282 from rural areas (47%, average age of 7.37 ± 0.47). In the sagittal plane, the most common were Class II/1 incisive type of malocclusions (40.0%) (fig. 1); in the vertical plane, deep bite (54.0%) (fig. 2); and in the transverse plane, the dental crowding (55.0%) (fig. 3).

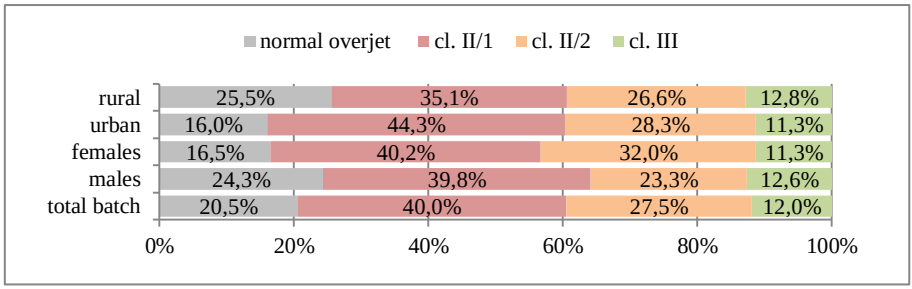

Fig. 1. The frequencies of malocclusions in the sagittal plane

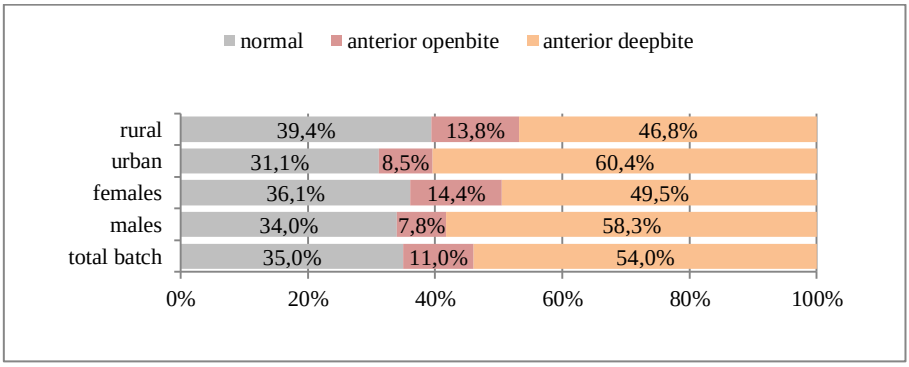

Fig. 2. The frequencies of malocclusions in the vertical plane

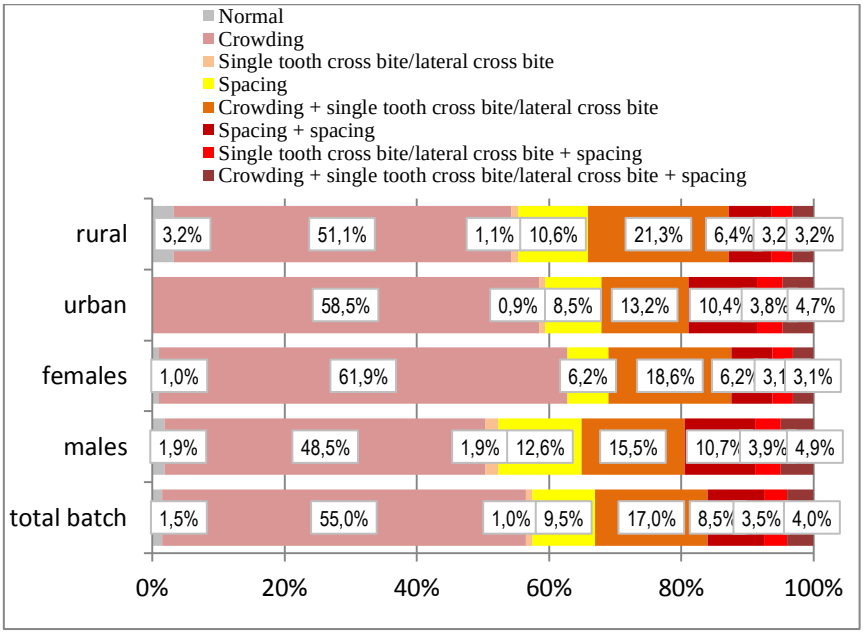

Fig. 3. The frequencies of malocclusions in the transverse plane

b. The characterization of dental status through DMFT/dmft indices of the malocclusion types. We found values ranging between 0-11 for the DMFT/dmft indices and the most common are between 0-5. The overall average of the DMFT/dmft index as quantitative variable is 3.64 ± 2.686 (tab. II).

For the anomalies in the sagittal plane, the mean values of the DMFT/dmft indices are between 2.95±2.314 and 3.66±2.762 and we found statistically significant differences between the mean values of DMFT/dmft index for Class II/1 versus (vs) Class II/2 incisive type (tab. III).

For the anomalies in the vertical plane, the mean values of the DMFT/dmft indices are between 3.41±2.543 and 3.50±2.543 and we found statistically significant differences between the mean values of DMFT/dmft index for patients with deep bite *vs.* patients without deep bite.

For the anomalies in the transverse plane, the mean values of the DMFT/dmft indices are higher (4.97±3.010 and 4.65±2.792) or lower (2.63±1.915), compared to the average values of normal occlusion (3.67±3.279).

We found several statistically significant differences between the mean values of DMFT/dmft index for patients with dental crowding and spacing associated with abnormalities in the transverse plane.

c. High values of DMFT/dmft indices as risk factors for the installation of various types of malocclusions. The presence of malocclusions in three planes is not influenced by increased values of DMFT/dmft indices (DMFT/dmft>5), except for the associated diagnoses of crowding and single tooth cross bite/lateral cross bite respectively crowding and spacing (tab. IV).

The relative risk of patients with DMFT/dmft>5 index is sub unitary for the anomalies in the sagittal plane Class II/1 and Class II/2 incisive type (statistically insignificant) and Class III incisive type (statistically significant, p=0.019). The relative risks of having anomalies in the vertical plane at patients with DMFT/dmft>5 index is statistically insignificant. For certain anomalies in transverse plane the sub unitary risks are statistically significant in the case of patients with crowding (p=0.001) and dental spacing (p=0.001). For the associated diagnostics of dental crowding and single tooth cross bite/lateral cross bite respectively dental crowding and spacing, the relative risk of patients with the DMFT/dmft>5 index is supra-unitary, more than 2.5 and statistically significant (p=0.000).

TABLE IV

The relative risks of developing malocclusions in conditions of high decay experience (DMFT> 5)

Variables	DMFT/dmft>5 (%)	DMFT/dmft≤5 (%)	OR	95% CI		p value

DISCUSSION

Previous attempts to demonstrate a direct connection between the presence of dental decays and malocclusions reported inconclusive results (9-11). Assessing the risk of developing a certain malocclusion due to high decay experience during mixed dentition represented the main objective of this article. The relation between different types of malocclusions and high decay

experience was analyzed in our study.

Many epidemiological studies concerning the interrelation of dental decay prevalence and malocclusions at children have been reported in the literature (9-20). Regarding decay experience, many of these studies have considered as benchmark the DMFT>0 (9-11, 14, 16). The Germanic guides consider that for the age of 6-7 years the decay risk is regarded when the DMFT/dmft > 5 index (22). This decay risk was assessed in terms of the installed malocclusion.

In our study, the indices DMFT/dmft presented lower averages for malocclusions in the sagittal plane relative to patients with normal overjet. Thus, it can be stated that the presence of high average values of the DMFT/dmft index for malocclusions in the sagittal plane is not a potential risk for the installation of these anomalies, but acts as a relative protective factor for the occurrence of such anomalies. However, other studies came up with additions like: dental decays were associated with an Angle Class II or III molar relation, in the cases of children with a DMFT>0 index, being two times more likely to be diagnosed with an Angle class II or III malocclusion rather than children without dental decay (23). Stahl et al. (9) found a statistically significant parallelism between the prevalence of dental decays and mandibular overjet in mixed dentition.

In the present study, the DMFT/dmft indices showed lower averages for anomalies in vertical plane compared to patients with normal overbite, also manifesting as a protective factor for the installation of these anomalies. But, additional studies have reached other results, namely: the probability of being diagnosed with an open bite is two times higher at children with dental decays than children without decay (23). Similar results were reported by Peres et al. among Brazilian children (24).

In our study concerning anomalies in the transverse plane, the DMFT/dmft indices presented lower averages at patients with dental spacing and higher averages at patients with dental crowding and single tooth cross bite/lateral cross bite and respectively crowding and regional spacing versus those without this type of anomalies. Once again this validates the theory that there is a close connection between dental decay and the occurrence of dentialveolar incongruence with dental crowding. It is well-known that the mechanism is the premature loss of temporary teeth consecutive to untreated dental decay, which determines subsequent migration of bordering, antagonists and permanent teeth successors. Similar conclusions were obtained by Marquesan et al. (14) in Italy, but concerning temporary dentition, stating that the severity of dental decay was significantly higher among children without anterior maxillary and mandibular dental spacing as well as at children with minimal overjet. The absence of spacing in the maxillary anterior segment was a risk factor for dental decay at preschool children.

In terms of the risk for the occurrence of anomalies in the transverse plane - separately, the high values of DMFT/dmft index acted as a protective factor, decreasing the chances of the installation of these anomalies.

The situation changed, however, concerning the same anomalies, but in the cases of associated diagnoses. Therefore, high values of the DMFT/dmft index presented a statistically significant risk (over 2.5) to develop dental crowding and single tooth cross bite/lateral cross bite respec-

tively dental crowding and spacing. The dental spacing also resulted from the premature loss of temporary teeth because of untreated dental decay (false spacing). Single tooth cross bite/lateral cross bite can be explained by the prolonged lack of masticator stimuli in the lateral area (all due to premature loss of temporary teeth because of untreated tooth decay), which may lead to the underdevelopment of the upper dental arch, this leading to the patient to undergo a change of the lateral occlusion. Proximal untreated decay of deciduous molars or the premature loss of second molars can lead to mesial migration of the permanent first molar and to the changing of the molar relation.

Similar results were obtained from Stahl et al. (9), who found a concordance between the prevalence of dental decays and posterior cross bite.

For the diagnostics of dental spacing with single tooth cross bite/lateral cross bite and respectively dental crowding with single tooth cross bite/lateral cross bite and spacing, statistics showed in our study that the DMFT/dmft>5 index values were correlated with decreased prevalence (subunit risk). These results can be interpreted as inconclusive, since patients who experienced these diagnoses were too few and the risk results were not statistically significant ($p > 0.05$).

Thus, the innovations in this study were represented by findings of high decay experience in mixed dentition (DMFT/dmft>5) which constituted a risk for developing certain malocclusions: dental crowding associated with single tooth cross bite/lateral cross bite and crowding associated with dental spacing).

This study suggests the need to develop national educational programs for the prevention of decay pathology, which constituted a risk factor in the development of dental malocclusions.

CONCLUSIONS

Our study found a high frequency of dental decay in mixed dentition with normal overjet and overbite. The high values of DMFT/dmft indices constituted risk factors in the installation of dental crowding associated with lateral cross bites, respectively dental crowding associated with false spacing. Future studies can be performed on other ethnicities and geographic areas to check the similarity to our study.

MEDICAL SAFETY (Abstract): At present, the concept of national security has also acquired a medical dimension, because the political and economic security of a country can be threatened also by the rapidity with which infectious diseases spread in the present global world or by the impact of climatic changes. The present paper intends to illustrate the main threats to/for population health, international organizations and their regulations in the field of medical security, the impact of epidemics on the population, economy and health systems, methods to prevent pandemics, as well as the situations in which the post-communist Romanian health system impacted politically the country image at national and international level. The improvement of the health infrastructure in Romania, motivating the medical personnel by creating better working and payment conditions, as well as the recent experience of other states in the epidemics that occurred in Asia and Africa can all contribute to the successful management of medical emergencies and infectious outbreaks. **Keywords:** MEDICAL SAFETY, INTERNATIONAL ORGANIZATIONS, HEALTH SYSTEM.

Motto:
The greatest test for humanity is the global health crisis. (Bill Gates)

After the ending of the Cold War, health became an interest point on the agenda of the security agencies in western countries (1). The concern for avoiding a nuclear conflict and for protecting the borders made room for an approach focused on the population needs, including medical ones, in defining national security (2).

In the current globalised world, political and economic stability of the states can be threatened by the rapidity with which infectious diseases spread. The pathogens can be easily transformed in weapons, either by terrorists or by certain states. The burden of certain diseases, the most quoted of which is AIDS, can be so severe that it can destabilize an entire region or country at social, political, economic and military level (1). Moreover, the occurrence of infectious outbreaks in various areas of the globe affects dramatically tourism and exports, or even consumption (3).

Medical security concerns protecting the population from the following dangers: infectious diseases, emergent diseases, HIV

virus, malaria, nosocomial infections, the microbial evolution and antibiotic resistance, the intentional release of dangerous chemical and biological materials, the contamination of food, biological weapons and bioterrorism, violence, humanitarian catastrophes, natural disasters, climatic changes, accidental release of chemical and radioactive substances, famine and poverty or, on the contrary, diseases connected to the modern and unhealthy life-style and consumption of processed food (obesity, cardiovascular diseases, diabetes, smoking and alcoholism), economic crisis, intensive agriculture (1, 2, 3).

Another threat to global medical security is represented by counterfeited drugs, because through their inefficiency undermine the credibility of health systems and international organisations, but also stimulate the development of microorganisms resistant to antibiotics (2).

Medical security has to have into consideration the possibility of offering universal access to health insurance. The state will create a legal framework through which the wealthy members of society would finance medical services for the sick and the poor (2). Only in the last century did people fully understand the importance of society and state for the therapeutic act, in which there are more factors involved beside the relationship doctor-patient. That is why, apart from the direct action of the doctor, the entourage and individual life-style, state policies and international organisations have begun to play an increasingly important role in ensuring the healthy state of the population (4).

Furthermore, the state can intervene in stopping the migration of a population scared by an epidemic outbreak, through informative campaigns regarding measures of preventing contamination. Following natural disasters or epidemics, the state can introduce reforms that might prevent the reoccurrence of those: improving the infrastructure and building hospitals resistant to earthquakes, providing free medical materials to population, etc. (2).

The spreading of infectious diseases is enhanced by a growth in population density and mobility, by wars and natural calamities and by the absence of epidemiologic surveillance services (5). A most recent risk is constituted by the current crisis of refugees from Syria, Afghanistan and other conflict areas, which overburdened the social and medical assistance systems in countries as Germany, Austria, Holland, Sweden or Norway.

That is why international cooperation represents an essential element of modern medical assistance. As medical safety was also interpreted by the Western world as a means of protection from the transmissible diseases originated in developing countries, the medical technology exchanges between the rich countries and the poor ones have to be interpreted not in terms of finances, but in terms of security. An example of this kind is represented by the 2007 refusal of Indonesia to provide the strain of avian influenza that appeared in the country, after the country had been refused the delivery of a vaccine obtained from a strain previously provided. This act that endangered the global medical security led to a normalisation of the access to the newest vaccines.

Medicine and infectious diseases permanently remind the states that managed to maintain a stable and social system, without military conflicts, of the danger caused by the lack of wealth transfer toward the less-privileged countries (2).

Military security is closely related and,

to a great extent, a guarantee to medical security. Armed conflicts generated epidemics. Thus, after the 1994 Rwanda crisis, cholera appeared in the Democratic Republic of Congo, and Marburg haemorrhagic fever devastated Angola in 2005. Moreover, ward destroys the medical infrastructure of the countries involved. In this respect, the Geneva Conventions regulate the impartial provision of medical assistance during international conflicts (2).

On the other side, there are situations in which armed forces come to support medicine. For example, as long as Ebola was considered a possible biological weapon, considerable funds were allotted for finding therapies (2). HIV infection was also perceived by the military as a threat to the stability of various countries, because of its rapid spread among the military people. For this reason, in 2000, the United Nations Security Council declared HIV virus a threat to peace and international security (6). The delay in taking the decision to destroy the smallpox sample from the secret laboratories in Russia and USA is again closely connected to military politics (2).

I. The concept of medical security – definition and history

The notion of security includes protection measures that can be taken against various threats to life and life quality (2). The protection of life involves maintaining health, reason for which traditional institutions involved in ensuring national security, such as the army, police and secret services, must be accompanied by health systems. Governments have to ensure the necessary conditions to avoid pandemics, in spite of the risk of corruption scandals due to the involvement of pharmaceutical companies. This is an increasingly important reality, as today insecurity is no longer caused only by the military arsenal of the states or by political conflicts, but also by the rapid circulation of diseases across borders (6).

Together with the great geographical discoveries the contact between civilisations facilitated the import of infectious diseases. 90% of Mexican population disappeared as a consequence of smallpox infection after the Spanish invasion. Smallpox was also used by the British against the American native population, during the colonial conflict. In 2001, in USA, letters contaminated with Anthrax were addressed to members of the American Congress and to journalists. In 2014, the Ebola epidemic in West Africa spread over several countries and in 2015 the respiratory syndrome in the Middle East (MERS) provoked an epidemic in South Korea, which, even if it was efficiently controlled, caused severe damage (5). Having in mind the impact of epidemics across many countries, the notion of collective health, as an extended version of public health, could be introduced when discussing about the concern for the health and wellbeing of the humankind, not only of the citizens of a particular state (2).

However, the upside of globalisation is that, even if it favours the spread of diseases, it might be regarded as a chance to control them, too. International cooperation contributes decisively to the successful prevention of epidemics. In addition, the economic effort of preventing the spread of an infectious disease implies enormous costs, being very difficult to undertake by a single country (1).

The term *medical security* was originally defined in 1994, in the Report for Human Development, elaborated by the United Nations Development Program of UNO

(3). In this report it is shown that the purpose of global security must include, among others, threats from the following areas: economic security, the security of food and environment, personal security, community security, political and *medical*.

In 2003, CHS - *Commission on Human Security* shifted the meaning of the security concept from national to individual level, including its medical aspects, such as protection against diseases and unhealthy lifestyle (3). Thus, a distinction can be made between a state perspective over medical security that regarded health problems as threats to national security and a global one that focuses on health problems at individual level (5).

In the attempt to limit the threats and vulnerabilities of public health caused by globalisation, which favours the appearance of pandemics, a document of the World Health Organisation issued in 2007 recommends eight directions for action: economic stability, international conflicts, climatic changes, biological and chemical threats, the stability of the international health system, HIV virus infection, emergent diseases and strengthening the concept of medical security.

Some of the international organisations that attempt to regulate medical security are World Health Organisation (WHO), Global Health Security Initiative, Commission on Human Security (CHS), established by United Nations Organisations (UNO), Asia-Pacific Economic Cooperation (APEC) and the agency of the European Union, European Centre for Disease Prevention and Control (ECDC) (1,3). These organisations analyse the public health risks represented by infectious diseases, biological, chemical and radioactive agents. Together with these international organisations there are numerous nongovernmental organisations for humanitarian aid as *Red Cross* or *Doctors without Borders*, as well as a new generation of philanthropists: Bill Gates, Warren Buffet or Ted Turner.

There are various documents concerning the control of certain diseases, such as HIV infection – 1308 Resolution of UNO Security Council (1) or biological weapons – Convention for Biological Weapons in 1975 (2). The extended immunisation program initiated by WHO and UNICEF at the end of the 70s by which poor countries were provided free or minimum- priced vaccines, succeeded in fighting tetanus, pertussis, scarlet rash and poliomyelitis in children. Framework Convention on Tobacco Control, elaborated by WHO in 2005 led to cigarettes over-taxation and reduction of smoking. In 1977 the Chemical Weapons Convention took effect (2).

In the mid-90s, WHO initiated Global Outbreak Alert and Response Network (GOARN), meant to provide a rapid response in emergencies and the Euro-Atlantic Disaster Response Coordination Centre (EADRCC) has the same objective (2).

As a reaction to the problems ascertained during SARS epidemic in 2003, in 2005 WHO revised the International Health Regulations. In 2014, the USA launched the Global Health Security Agenda (GHSA) in partnership with various international organisations (5).

The lifestyle in industrialised societies promoted a diet rich in calories but lacking nutritious properties, with a large consumption of meet, alcohol consumption and smoking and the use of personal vehicles. All these have eroded the medical successes following the control of infectious diseases and malnutrition (2). In other words, the developed countries are confronted

with their own threats when it comes to the population's health and wellbeing, only that they are different from the ones in poor countries. That is why the mechanisms of medical security do not only concern protecting the Western world by the viral threats coming from developing countries (1). In the same vein, resistance to antibiotics has come to afflict even the best equipped hospitals in the Western countries (2). Hospital overpopulation in metropolises has as a consequence a slower medical response, even if more proficient (5). The activity of pharmaceutical companies focused more on making profit, competitors and market demand and less on the actual health needs of the population led to the excessive and useless usage of numerous antibiotics which gradually lost their efficiency, developing more resistant strains. This in turn generated excessively high prices to treatments that are necessary, as C hepatitis, and maintained a culture of secrecy regarding medical research, with visible negative effects in doubling, fragmentation and delay of results (2). If in developing countries, the main cause of mortality and morbidity is represented by infectious diseases, in industrialised and urbanised countries the danger comes from an unhealthy lifestyle (3).

II. Measures for maintaining medical security

The first case in which it is known that medical security measures were taken was the plague epidemic in the 14th century, when quarantine was instituted in order to prevent the spreading of bubonic plague across borders (2).

The main actions initiated in case of epidemics or biological weapon attacks are surveillance and emergency intervention. Transparency of information is very important, because timely warning prevents the propagation of infection. An important step in the timely signalling of epidemics was represented by the fact that WHO extended its prerogatives and now can it receive information on potential infectious outbreaks, even in the situation of a single isolated case, not only from governmental sources, but also from nongovernmental organisations (1). Furthermore, the list of diseases considered a threat in the WHO International Health Regulation of 2005 extended over the six initial ones: cholera, plague, recurrent fever, smallpox, typhus and yellow fever, including newer diseases such as HIV, SARS or H5N1 influenza (6).

The efficiency of epidemic control interventions is ensured through the instruction of the medical personnel, improvement of public communication strategies, the existence and functioning of decontamination units and the establishment of vaccines and antiviral medicine reserves.

Global interventions are as useful as those at local level are. WHO can take measures across borders, which include issuing travelling alerts and formulating a list of recommendations, such as those for infection prevention and control (1). The direct involvement of international organisations in the inflicted areas, by sending medical personnel and materials, means that the main measure for controlling the epidemics is no longer borders control. In fact, it is the control of the outbreak in the inflicted area, especially considering that during the latest Ebola epidemic in West Africa the restriction of circulation across borders blocked the access of foreign medical personnel and of international humanitarian aid (1, 2).

At local level, the following measures

are applied: rapid identification of cases (conformed by lab analyses), quarantine (at home or in hospital) and monitoring all contacts (by interviewing, monitoring surveillance cameras and GPS localisation of mobile telephones), closing schools and altering employees' working programs, instructing the primary care givers that tend for the sick persons at home, cancelling public meetings and shows, informing citizens and international partners and involving police forces in the case of uncooperative persons (2, 5).

The organisation of an efficient national health system will guarantee the termination of infectious diseases epidemics produced naturally or following a bioterrorist attack. Such a health system has to isolate the pathogens securely, to have a laboratory network all over the country, equipped with reference samples for various pathogens, an electronic system for reporting infectious diseases, qualified medical personnel and at least a field epidemiologist for every 200,000 inhabitants, as well as a public health centre for emergency operations, capable of offering an emergency response in 120 minutes (5).

Medical security in post-communist Romania

In the 80s, among the institutionalised children in Romania there was a rapid spread of the HIV virus infection. In the communist period, Romania provided false reports to WHO, so that before December 1989 the data indicated the existence of only 13 AIDS cases. At the end of 1990, the Romanian Ministry of Health registered 1168 patients with AIDS, 93.7% of which being children with ages under 13.683 of the cases were institutionalised children that had received treatments against anaemia or malnutrition through blood transfusions or various injections, without a previous correct sterilisation (8, 9).

This episode, in which the sterilisation techniques are the cause for the spread of an extremely dangerous virus, brings into discussion the media scandal around the accusation of diluting the disinfectants provided by HexiPharma Company that attracted the public attention on the alarming dimension of the nosocomial infections phenomenon in Romanian hospitals. In addition, ever since the beginning of the 90s, Romania has been perceived internationally as the country of abandoned and neglected children.

In the summer of 1996, the Southeast of Romania, especially Bucharest, was affected by an encephalitis epidemic determined by the West Nile virus, which caused 17 deaths and 393 cases hospitalised (10). The episode draws attention to the necessity of maintaining the urban infrastructure in optimal conditions, by eliminating the water from building basements and thus stopping the proliferation of mosquitoes.

The absence of a rapid and efficient medical intervention during the fire outbreak from Colectiv, the Bucharest club, caused the fall of the Government led by Victor Ponta, incident that demonstrates the importance of ensuring the medical security of the population in maintaining the political stability in the country. Even though the efficiency of SMURD (Mobile Service of Emergency, Reanimation and Extrication), the intervention unit for providing medical and technical assistance in emergencies, was criticised, the establishment of this service that operates in collaboration with the aviation structures in the Ministry of Administration and Internal Affairs shows that the use of military tech-

nical arsenal in civilian purposes marks an important step in the efforts to improve medical services.

A more subtle threat to medical security in Romania is constituted by the massive migration of the medical personnel toward countries with better performing medical systems. The loss of well-prepared doctors and nurses leads both to a personnel shortage, which block the activity of some hospital sections, as well as to the superficial and rapid recruitment of new medical personnel, without having the guarantee of their competence.

CONCLUSIONS

Certain diseases have become to be regarded not only as public health issues, but also as aspects of national and international security. Medical security represents a relatively new concept, which gradually came to the attention of governments all around the world. The media scandals in which institutions from the Romanian sanitary system were involved drew attention to the importance of ensuring population health for the social, economic and politic stability of the country. A consistent improvement in the medical infrastructure in Romania, increasing the motivation of medical personnel, by creating better working conditions, as well as the recent experiences of other states with the epidemics that affected Asia and Africa could contribute to the successful management of medical emergencies and infectious outbreaks.

PELVIC ACTINOMYCOSIS MIMICKING A LOCALLY ADVANCED PELVIC MALIGNANCY - CASE REPORT

PELVIC ACTINOMYCOSIS MIMICKING A LOCALLY ADVANCED PELVIC MALIGNANCY - CASE REPORT (Abstract): We present the case of a former user of an intrauterine contraceptive device (IUD) for 10 years, diagnosed with a bulky, fixed pelvic tumor involving the internal genital organs and the recto sigmoid, causing luminal narrowing of the rectum, interpreted as locally advanced pelvic malignancy, probably of genital origin. Intraoperatively, a high index of suspicion made us collect a sample from the fibrous wall of the tumor mass, large *Actinomyces* colonies were thus identified. Surgery consisted in debridement, removal of a small amount of pus and appendectomy, thus avoiding a mutilating and useless surgery. Specific antibiotic therapy was administered for 3 months, with favorable postoperative and long-term outcomes. Pelvic actinomycosis should always be considered in the differential diagnosis of pelvic tumors in women using an IUD. The association of long-term antibiotic treatment is essential to eradicate the infection and prevent relapses.
Keywords: ACTINOMYCOSIS, INTRAUTERINE DEVICE, PELVIC TUMOR.

Actinomycosis is a chronic infection most commonly caused by strains of *Actinomyces israelii,* a gram-positive, anaerobic, filamentous, non-sporulating bacterium (1,2). It causes a chronic suppurative inflammation with formation of multiple abscesses, sinuses and recurrent fistulas and abundant granulation and dense fibrous reaction tissue. Pelvic actinomycosis is found in about 3% of cases (3). Although the abdominal form of disease can extend directly to the pelvis, pelvic actinomycosis is mainly associated with intrauterine contraceptive devices (IUD) (4). The clinical presentation is mostly nonspecific, mimicking a tumor process (5,6). Moreover, the radiological findings are also nonspecific, making an accurate diagnosis difficult (7). This explains why patients often undergo extensive surgery involving multiple organ resections, with a correct diagnosis being made postoperatively by anaerobic cultures and histopathologic examination. We present the case of a female patient with pelvic actinomycosis diagnosed as locally advanced ovarian cancer in which the diagnosis was made intraoperatively, thus avoiding useless extended resectional surgery.

The diagnostic difficulties and treatment strategies are discussed.

CASE REPORT

A 51-year-old female patient with altered general status was admitted for investigations and treatment of a pelvic tumor mass. The onset of symptoms was insidious, over 4 months, with abdominopelvic pain associated with abnormal vaginal bleeding and a tendency to constipation, low grade fever, anorexia, marked physical asthenia and weight loss of 8 kg. From her personal history we found that the patient had been using an IUD for 10 years, being removed two months earlier. Physical examination on admission revealed a hard, palpable, imprecisely delimited mass in the hypogastrium. Laboratory tests showed leukocytosis (13.800/μL) with mild neutrophilia and anemia (hemoglobin level 10.9 g/dL). C-reactive protein levels were within normal range. Other laboratory tests including tumor markers were all within normal range, except CA 125 which was slightly elevated 19.80/mL. Vaginal examination revealed the presence of a pelvic mass occupying the vaginal vault, encompassing both parameters and an immovable cervix. Uterine curettage showed only an unspecific inflammatory process. Colonoscopy identified rectal extrinsic stenosis of approx 3 cm, at 10 cm from the anal verge.

Pelvic magnetic resonance imaging (MRI) showed a tumoral mass of 74/84/75 mm that included the posterior vaginal wall, extending to the right piriformis and *levator ani* muscles, involving the medial and lower mesorectum (fig. 1).

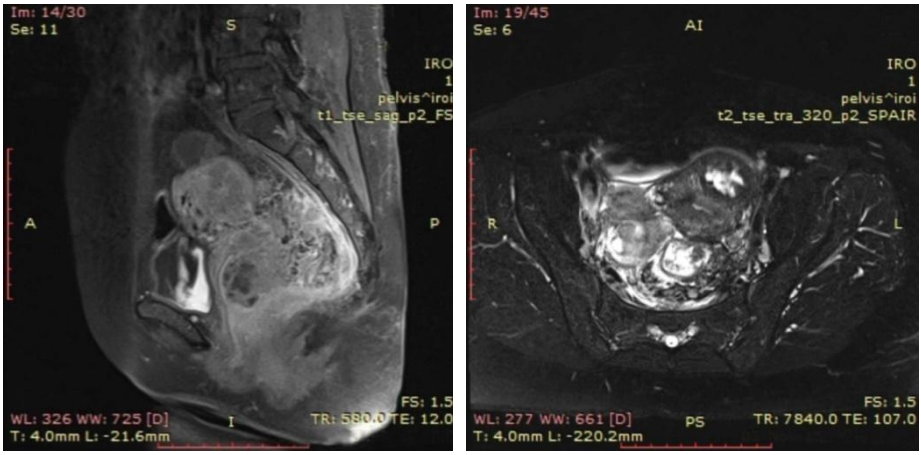

Fig. 1. Pelvic magnetic resonance imagingshowed a tumoral mass of 74x84/75 mm that includes the posterior vaginal wall and extends to the right piriform and levator ani muscles involving also medial and lower mesorectum. A second mass of 52x40/52 mm, located to the right and posterior of right broad ligament is noted.

This tumor was centered by the ampulla recti, with probable invasion of the anterior rectal wall. Another mass of 52x40/52 mm, of unknown origin, located on the right and posterior surface of the right broad ligament was noted. Considering the suspicion of right ovarian tumor, a triple contrast CT was performed identifying gas bubbles in

the uterine cavity. The presence of right obturator and left external iliac and interaortico-cavous enlarged lymph nodes was also noted (fig. 2).

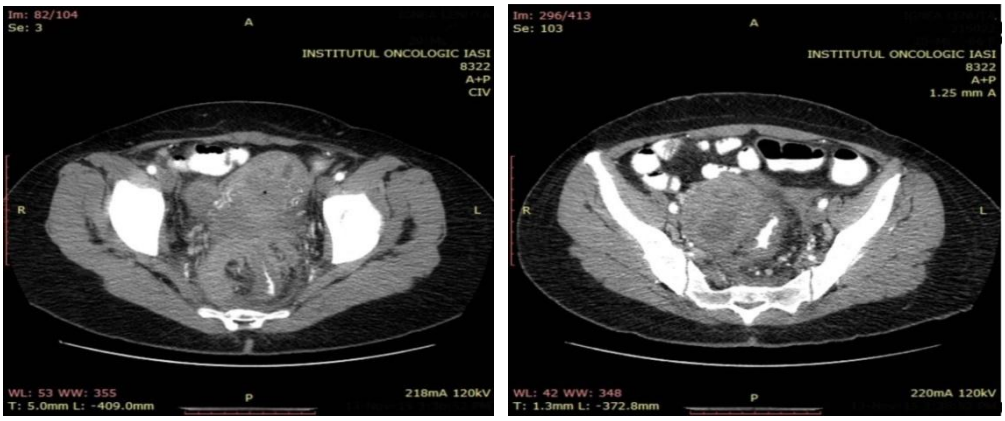

Fig. 2. Pelvic CT scan showing an in homogeneous mass involving internal genital organs without separation from rectum and enlarged pelvic lymphnodes.

A left basal pulmonary nodule of 5 mm with uncertain features was identified. A preoperative diagnosis of locally advanced pelvic malignancy of unknown origin, was made and surgery was indicated. Exploration of the peritoneal cavity revealed a bulky, hard, irregular, fixed, infiltrating abdominopelvic mass involving the uterus, annexes, rectum, small bowel loops and vermiform appendix. During dissection a small amount of pus was exteriorized and collected for cytology and bacteriology exam. At that moment a sample of tumor/abscess wall was removed and sent for fresh-frozen examination which found multiple areas of polymorphous inflammation with abscess formation with large, central, filamentous *Actinomyces* colonies. Surgical debridement, appendectomy, peritoneal lavage and drainage were performed. Pathology established the final diagnosis of pelvic actinomycosis (fig. 3).

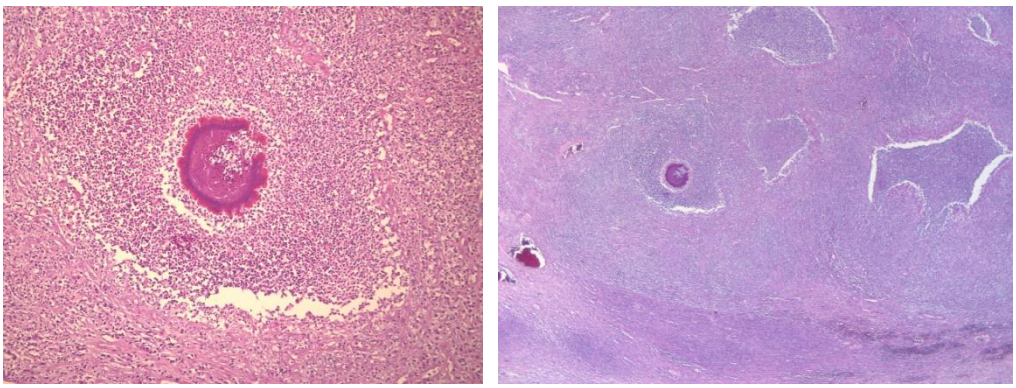

Fig. 3. Abscesses with large, central, filamentous *Actinomyces* colonies (a. HE x25; b. HEx100).

High doses of intravenous penicillin were commenced immediately. The postoperative course was uneventful with the patient being discharged on the 7th postoperative day. The antibiotic therapy was continued with high-dose penicillin for 4 weeks followed by oral penicillin (Augmentin 3g/day) for a further 6 months. A three months' follow-up exam by MRI showed almost normal postoperative appearance of the pelvic region and no clinical complaints (fig. 4).

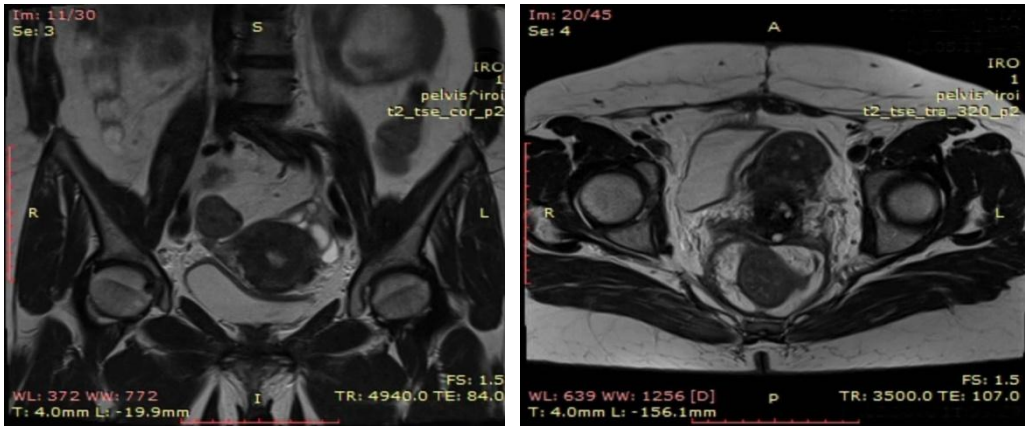

Fig. 4. Three months postoperative – MRI exam almost normal of pelvic region

DISCUSSION

Actinomycosis is a rare infectious disease, its true incidence being difficult to define because many cases with mild infection are probably eradicated through the common use of antibiotics. The abdominopelvic location is responsible for about 20% of human cases (1,2,8). It is generally accepted that actinomycosis has become a less frequent disease, unlike abdominopelvic actinomycosis which has an increasing prevalence due to the increasing use of IUDs. The first case of abdominopelvic actinomycosis associated with IUD was reported by Henderson in 1973. The incidence of *Actinomyces israelii* in IUD users is differently reported by various authors, ranging from 1.6% to 20% (1,4,6) and it increases with duration of IUD use, the mean duration of usage in patients with actinomycosis being about 8 years (7,9). These devices cause prolonged trauma to the endometrium, inducing areas of necrosis in the presence of pre-existing pelvic inflammatory disease, providing a favorable environment for the development of actinomycosis. Disruption of the mucosal barrier of cervical mucus allowing the ascension of germs or detachment of small fragments from the device which could act as foci of infection are other supposed mechanisms (6,7). The main problem related to actinomycosis is the difficulty of preoperative diagnosis, this disease being rightly called the great mimicker (4,7,8). The clinical and imaging features often mimic malignant lesions, inflammatory diseases, tuberculosis, fungal infections, endometriosis (5,9). The most common presenting features, as in our case, are abdominal pain, weight loss and physical weakness associated with abnormal vaginal

bleeding. The tumor related symptoms are often in the foreground with a poorly delimited, fixed and painful pelvic mass accompanied by altered general status, cachexia, and sometimes fever. The biological inflammatory syndrome is constant and the CA 125 is sometimes elevated, as in our case (1,2,4,8). Extension to adjacent organs is possible, especially to the bladder and recto sigmoid with a tendency to fistula formation (9,10). Retroperitoneal involvement is common, causing ureteral and/or vascular compression and sometimes hydro nephrosis or thrombophlebitis (11,12). The lymph nodes are not usually involved, and spread into the peritoneal cavity is exceptional (4,7). The presence of a pelvic tumor mass with frozen pelvis appearance, with rectal stenosis and interaortocaval, left external iliac and right obturator enlarged lymph nodes, created confusion, pleading for the neoplastic nature of the lesion in our case.

Imaging diagnosis of actinomycosis is difficult. Frequently, the seemingly aggressive nature seen on CT or MRI might lead to the suspicion of a malignant disease. Lee describes the main radiological findings in abdominal actinomycosis. Each radiological finding may mimic an abdominopelvic tumor process, therefore a correct differential diagnosis is essential. (5,9,13). The CT scan typically shows a solid, inhomogeneous mass, or a cystic mass with thickened wall surrounded by inflammatory infiltrate in the adjacent fat (5,9). The MRI may help in diagnosis, but has a low specificity (5,13). Recently PET scan has been used to diagnose infectious and inflammatory diseases, but it is unfortunately not specific for actinomycosis. It could however be used to evaluate the efficacy of antibiotic therapy (13).

In terms of histopathology a characteristic chronic inflammatory response is found, with pus production and abscess formation centrally and granulation tissue in the periphery. In this atmosphere of destroyed and damaged PMNs, bacterial colonies of filamentous *Actinomyces* are identified. Confirmation may also be obtained by fine needle aspiration or biopsy under radiologic guidance or during surgical exploration (1,2). Unfortunately, many authors report highly variable rates (1-50%) of isolation of *Actinomyces* species from the histologic material (1,2,4,14, 15,16). In our case, the intraoperative fresh frozen examination identified large filamentous colonies of Actinomyces. The literature also reports the presence of Gram-positive "sulfur granules", with a mycelium-like structure, positive on PAS and Grocott staining's, which are unfortunately non-specific (1,4). The morphologic picture can be attenuated by prior antibiotic treatment thus histological tests should be carried out before the initiation of antibiotic treatment (2,4).

The presence of *Actinomyces* without apparent pelvic infection does not require IUD removal and antibiotic treatment, but many authors believe that a vaginal smear positive for *Actinomyces* is an indication for antibiotic treatment to eradicate the infection or recommend IUD replacement at 4 years (6).

Standard treatment is based on intravenous penicillin G for 2-6 weeks, followed by oral penicillin V (2-4 g/day) for 6-12 months due to the limited penetration into the fibrous tissue and tendency to recurrence (1,8). The risk of developing penicillin resistance is cited as very low. In preg-

nant women, erythromycin can be safe, and in patients who are allergic to penicillin, doxycycline, clindamycin and erythromycin are adequate (14,15,17). In case of concomitant intraabdominal infection with anaerobic bacteria, the combination of amoxicillin and clavulanic acid with metronidazole, or clindamycin can be used. However, the literature shows a high rate of recurrence after antibiotic therapy alone (2,15). Definitive indications for surgical treatment are: abscesses that are not amenable to percutaneous drainage, extensive necrotic tissue, local complications such as compression or stenosis, to rule out a malignant disease, or when medical treatment is inefficient. Complete removal of infected tissue is rarely possible, with a high risk of recurrence. It is very important to make or suspect the diagnosis intraoperatively, because most often a pelvic malignancy is suspected and patients undergo major surgery. (8,14,17).

The prognosis is favorable with long-term antibiotic treatment. Some authors have shown that a combination of complete surgical resection followed by short-term antibiotic treatment is also an effective therapy (1,17). However, severe complications due to local or generalized spread of infection have been reported, justifying the prolonged surveillance (14,15).

CONCLUSIONS

In this case pelvic actinomycosis pelvic, rare infection associated with the use of an IUD over a long period of time, mimiking a locally advanced pelvic malignancy. Therefore, actinomycosis should be included in the differential diagnosis in women with presumed pelvic cancer and a history of long-term use of IUDs. The primary goal of surgery is to obtain a clear evidence for histopathological diagnosis and surgical treatment should be limited to debridement and drainage. Essential to eradicate the infection and prevent recurrences is the association of the specific antibiotic treatment.

COMBINED EFFECT OF THERMAL LOAD AND MECHANICAL LOAD IN TRANSTIBIAL PROSTHESIS. AN EMPIRICAL STUDY (Abstract): Probably the most important factor in evaluating a patient's prosthesis is quality of life. Transtibial amputations, are among the most frequently performed major limb amputations. Many individuals with transtibial amputations successfully achieve rehabilitation at or near their preamputation levels. Discomfort in prosthetic sockets continues to be a critical challenge faced by both prosthetists and amputees. **Material and methods**: This paper proposes a fusion Graphic User Interface that combines two types of information (pressure and temperature). Data from pressure sensors and thermistors (an electrical resistor whose resistance is greatly reduced by heating, used for measurement and control) placed on the stump in transtibial prosthetics are collected in real time using a National Instruments Data Acquisition device. **Results**: All the data stored in files are available for offline processing. The user has the possibility to analyse the signal by zooming or positioning the marker and window on different parts of signal. A complex analysis that involves the pressure and temperature for a location (where both sensors are placed) is available in time domain. **Conclusions**: Blunt-prosthesis interface is characterized by few parameters among the most important are pressure and friction. The action of these parameters during static and dynamic stage is very important because their actions can produce lesions of skin at the level of interface.Despite the advancements in surgical techniques and prostheses, much still needs to be done. We made certain that the sensors were in the same location by pressing on specific cells on the residual limb during various stages of the experimentation. The highest pressures recorded were during the stance phase of walking. The curve that shows the temperature evolution or pressure in one point could differ in different points from patient to patient.
Keywords: BLUNT,GRAFIC INTERFACE, TRANSTIBIAL PROSTHESIS, THERMISTOR, THERMAL LOAD.

The interface skin-liner has a distinctive achievement consisting in a comfortable prosthesis for a person with lower limb amputation. Amputation is a surgery that involves the section of anatomic parts: bones, muscles, blood vessels and nerves. A study of the interface-level pressures presents a particular interest in determining the patient's comfort and quality of life (1,2).In (3) the authors propose placement of six sensors in locations chosen based on experimental criteria to cover pressure

zones for two persons with transtibial amputation. One of the main purposes is to identify areas with maximum pressure variation of these values depending on the patient's activity. A performance investigation of the patient's comfort is proposed in (4). The authors used a four F-Socket sensors array 9811 and a Prosthetic Evaluation Questionnaire which investigates patient satisfaction in relation to the two liners used (4). But from the point of view of registration equipment and pressures of the software, this solution is expensive.

In the last years, few papers discussed the influence of temperature on patient's comfort. Temperature values at skin-prosthetic interface are recorded for different points on stump and the influence of ambient temperature is also discussed. The permanent contact of inorganic materials with skin can cause cutaneous pathology (1).Recent studies reveal the fact that a 2^0 C increase of skin temperature in residual limb can create discomfort (2). Thermal comfort satisfaction is strongly related with ambient temperature that has influence over skin temperature, perspiration and all thermal processes in stump, skin, liner and socket (3).This study reveals that from 38 studies published in PubMed and Web of Knowledge, at least 53% of persons with amputation faced discomfort due to heat, perspiration or both inside their prosthesis, most of them having transtibial amputation. A collection of 16 thermistors and a portable signal acquisition system to record temperature curves is proposed in (4). The thermistors are placed uniformly on the stump and the evaluation of temperature evolution is made using an activity protocol of 30-minute walk bordered by 60 minutes of rest (4). A map of temperatures is presented using thermal contour plots. A new approach to record the temperature on surface of the residual limb is proposed in (5). The protocol uses Gaussian Process for Machine Learning for predictive model that has as input the liner temperature and as output the temperature of the skin located on the residual limb (5).A simple method to describe the temperature on interface skin-prosthesis is proposed in (6). The authors used 16 thermistors placed in a regular grid on stump surface to collect data. One subject was selected for test in 1h protocol rest-walk-rest. Thermal plot contour type was deduced using Matlab in an offline application. An average value of temperature over all 16 thermistors has been calculated in order to deduce the influence of thermal environment on skin-prosthesis interface (6).The experimental studies revealed the fact that a lower temperature at skin level usually reduces the patient's discomfort both due to ambient temperature and wearing of prosthesis. Few researches oriented toward thermal conductivity of materials that are used for construction of prosthesis. Thermal conductivity of materials has been calculated using Fourier's law. One of the most important conclusions of the paper is that the thermal discomfort is reduced in the case of multilayer sockets that use materials having high thermal conductivity (7). A 3-D thermal finite element model is proposed in (8). Thermal characteristics of the tissues (muscle, fat, skin, bone) and prosthetic materials were taken from literature. The skin temperature was predicted using Penne' BHT equation of heat transfer (8). The thermal performance of prosthesis is one of the very important objectives in prosthetic design (9, 10). A socket modification, a cooling channel inserted in socket, is proposed in (9). A socket prototype was created in SolidWorks and implementation was made using a 3D printer

(9). A thermoregulatory system was proposed in (11). The authors verified the system using a phantom model, silicone liner and a thin layer on aluminium as transfer interface between thermal pump and different locations situated on phantom (11).A finite element method is used in (12). The authors propose to use finite element method in modelling temperature distribution at skin surface in order to predict it depending on external conditions. Some authors used the experimental results to design novel prostheses (13) or a complicate system for thermoregulation of temperature inside socket (14).

MATERIAL AND METHODS

A graphical interface is an interface located between the user and electronic devices such as computers, hand-held devices (mp3 players, portable media players), electronic appliances and some office equipment. To present all available information and actions, a GUI provides icons and visual indicators, in contrast to text-based user interfaces, which provide names of commands to be typed in or text navigation. This is intended to facilitate the user's work by eliminating the process of writing the software code. For recording purposes, pressure sensors were used on type CZN-CP6 (pressure sensors) and CZN-CP9 (pressure sensors) self-adhesive wiring diagram to measure resistive input in measuring plate. An analogue digital converter used precise 14-bit resolution, and six sensors were placed in locations determined experimentally in areas with the highest solicitations (and therefore a higher pressure) according to fig. 1.

Ten thermistors of MA100GG type were placed on the sink of the stump in an experiment including a group of three patients with transtibial amputation: A1 (67 Kg, 27 years, male), B3 (30 Kg, 10 years, male) and C4 (76 kg, 32 years) (fig. 2). The thermistors are validated before using the water-bath procedure. The other patients with other diseases, e.g. diabetes, were excluded from the study.

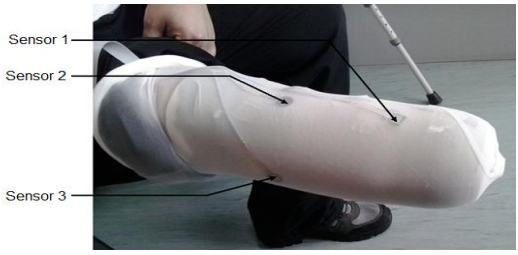

Fig. 1. Pressure sensors

Fig. 2. Thermistor locations

Experiments were conducted by using a protocol that began with a 30-minute walk at fixed speed (a trade off between the speed's options of the two patients) and a 30-minute rest before repeating the experiment. The sensors were placed on the areas known as being the most solicited pressure locations during walk (e.g. lateral side, medial side, distal, etc.). Also, other experiments used a 2D map of the stump split in approximated rectangles with an algorithm for sensors placement in order to identify the most solicited areas by temperature evolution during walk. Finally, all the shortcomings are reflected in the patient's sensation of discomfort. In time, a combination of pressure and temperature can lead to serious affections of skin and teguments

RESULTS

A Graphic User Interface is proposed to analyse offline data collected from pressure sensors and temperature sensors. After authentication, the user can select the two options: Force (pressure) data or Temperature data. Data are collected online using a National Instruments Data Acquisition device and the files are stored in ASCII format. Data acquisition is the process of measuring an electrical or physical phenomenon such as temperature, pressure ith a computer.Records for the same patient (pressure and temperature) are statistically processed. Outliers are removed and replaced by a median value, and the points outside value bordered by ± SD (standard deviation are excluded). The most probable curve is computed from the rest of the points using the LMS (Least Mean Square) method.

The interface has a module that allows calibrating the sensor, the curve being approximated by a polynomial model (a polynomial with maximum degree 7). Practically, the coefficients can be stored individually for each sensor or for all sensors for future purpose. The curve that shows the temperature evolution or pressure in one point could differ in different points from patient to patient.

Probably the most important factor in evaluating a patient's prosthesis is Quality of Life. The most common evaluation of this factor uses questionnaires, the Prosthetic Evaluation Questionnaire being one of the most used in practice (15). Prosthetic Evaluation Questionnaire was developed to provide quantitative measures for patient's satisfaction using 54 qualitative questions. One of the most common materials was used for all patients' prostheses: socket – PP/PE (90% Polypropylene, 10% ethylene), Young's module = 1.5 GPa, Poisson coefficient = 0.3 and liner - soft Pelite (is a polyethylene closed cell foam commonly used as an interface material in prosthetics), with Young's module = 0.38 MPa, Poisson coefficient = 0.39. In this stage of research, we want to measure the degree of comfort using Prosthetic Evaluation Questionnaire for all three patients. Average empiric coefficients were set for fused data, pressure and temperature (a = 0.9 for pressure and 0.1 for temperature). The final Prosthetic Evaluation Questionnaire was found to be 43, 56, and 38 for three patients, which suggests that it is possible for some pairs of socket-liner materials not to be very adequate for some patients. These values are suggested by the fast variation in force versus time (5-6 sec) and a very slow modification in temperature in the same time interval, constant in practice. Further investigation is needed, using new models which study how temperature can affect the patient's discomfort sensation caused by a pressure (force) on the skin at skin-liner interface.

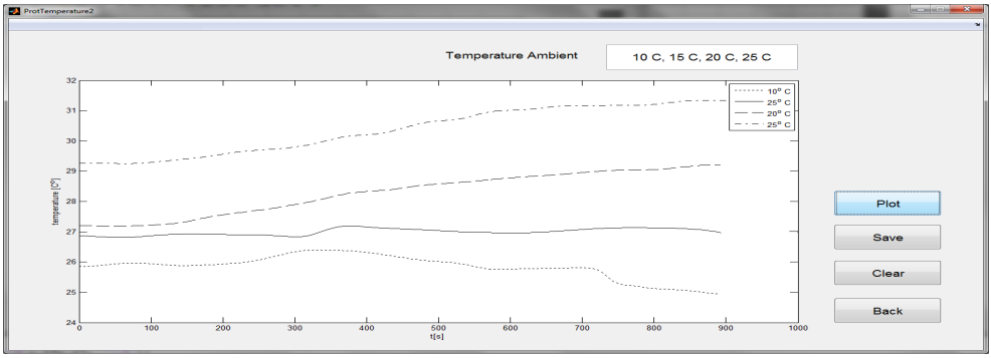

Fig. 5. Wave form temperatures, sensor 3, pos. 5, medial position for ambient temperature 10° C, 15° C, 20° C, and 25° C.

CONCLUSIONS

In this article, Graphic User Interface may contribute towards improvement in the quality of socket design for amputee patients. This interface has been the most common computer modelling method used to try to predict stresses at the socket interface. The contact zone between two

surfaces generates two types of friction, static friction and kinetic friction. The quality and comfort of a prosthetic socket can determine the daily duration for which patients use their artificial limbs. More studies are necessary to find a relationship between patient's comfort sensation and materials used in prosthetic. Beside a custom approach for each patient, statistic studies need to include other factors, such as age or sex. It is clear that a large group of subjects and medical validation are necessary before these preliminary results become applicable.

DIVALENT CATIONS PROFILE IN PATIENTS WITH LIVER CIRRHOSIS AND VARICEAL BLEEDING (Abstract): **Aim**: The objective of this study is to evaluate divalent cations serum levels (magnesium, zinc, copper) in liver cirrhossis and one of its major complication (variceal bleeding). **Material and methods**: A prospective case-control study including 60 patients with liver cirrhosis complicated with variceal bleeding admitted to the Emergency Department, and 35 subjects without liver cirrhosis which served as group control. Serum concentrations of zinc, copper and magnesium were determined using atomic absorption spectrophotometer. **Results**: The concentration of magnesium was significantly lower between patients with liver cirrhosis (11,6 ± 2,77mg/l) vs group control study (17,7 ± 3,86 mg/ l) ($p<0,001$), regarding decreased magnesium levels and the presence of complications as hepatic encephalopathy, ascites (Child C class). Serum concentrations of zinc were decreased (0, 77 ± 0, 35 mg/ l) compared to control group ($p< 0,001$) in patients with liver cirrhosis and variceal bleeding. Serum levels of copper were increased (1, 69 ± 0,722 mg/ l) compared to control group in patients with liver cirrhosis and variceal bleeding and are also correlated with serum albumin levels ($p<0,001$, Pearson coefficient r-0.631). **Conclusions**: Variceal bleeding in patients with liver cirrhosis is associated to important imbalances in blood concentrations of zinc, copper and magnesium. **Keywords**: LIVER CIRRHOSIS, ZINC, COPPER, MAGNESIUM.

Zinc, copper and magnesium are essential trace elements with role in the normal functioning of the liver. Zinc is associated with more than 300 enzymatic systems (1). Zinc augments the natural defense of reactive oxygen radicals by Zn-enzyme Cu-Zn superoxide dismutase (2). Zinc acts as an antioxidant, a membrane and cytosceletal stabilizator, an anti-apoptotic agens, an important co-factor in DNA synthesis, an anti-inflammatory agents etc (3).

Copper is an essential trace element which participates in many enzymatic reactions. Its most important role copper has in redox processes. Reactive copper can participate in liver damage directly or indirectly, through Kupfer cell's stimulation (4). Copper's toxic effects are related to oxidative stress(5).

Magnesium is important for the protein synthesis, enzyme activation, oxidative phosphorilation, renal potassium and hy-

drogen exchange. It is also involved in immunoglobulin synthesis, immune cell adherence, antibody- dependent cytolysis, IgM lymphocyte binding, T helper B-cell adherence and additional responses (6). Only 0.3% of total body magnesium exists in serum. Magnesium deficiency have been reported in various disorders: diabetes mellitus, malabsorption syndromes, chronic alcoholism bronchial asthma, epilepsy, and ischemic heart diseases. There are contrary reports about their serum concentrations in patients with liver cirrhosis**.**

Since zinc, copper, se and magnesium have a possible role in the pathogenesis of cirrhotic complications**,** the aim of this study was to investigate the serum concentrations of mentioned trace elements in patients with liver cirrhosis with variceal bleeding and compared them with concentrations in controls group patients.

MATERIAL AND METHODS

Material. This study is a prospective case-control, in which we determined serum concentrations of Mg, Zn, Cu in patients with liver cirrhosis complicated with variceal bleeding and compared with a control group of patients. The study included patients admitted to the Emergency Departement of "St.Spiridon" Hospital Iasi in the interval April 2013 – September 2014. The diagnosis of liver cirrhosis was established by detailed history of all such patients, positive findings on clinical examination, relevant biochemical tests, ultrasound and endoscopic findings. The diagnosis of variceal bleeding was established on anamnestic data with hematemesis and melena and gastrointestinal endoscopy. Exclusion criteria were malign disease, acute liver failure, renal failure, multiorganic failure, collagen disease, hypertension, heart failure, ischemic heart disease, psychiatric disorders. The control group included subjects with no history of liver disease, heart disease and renal disease, matched with patients with liver cirrhosis for gender and age, who were performed laboratory analysis as part of systematic medical examinations.

Ethical considerations

All the patients enrolled in the study signed an informed consent, through which they were given details on the aim of the study, its methodology, the risks and benefits incurred by the study, as well as information regarding the confidentiality of the results obtained. The study was approved by the local Ethics Committee and was in accordance with the Helsinki Declaration of 1975.

Methods. Blood samples were collected from the cubital vein with all aseptic precautions in glass tubes free from electrolytes. Serum was separated and serum concentrations of magnesium, zinc, copper were measured by spectrophotometer at 510-580 nm. The separation of serum for further analysis was performed by centrifugation at 4000 revs/min for 10 minutes. It was separated by 1 ml of serum in digestion tubes, over which were added 2 ml of concentrated nitric acid and 2 drops of concentrated per chloric acid. The tubes are placed on a plate heated to 130-150 ° C. Once the volume in the tube reached 1 ml, the temperature is brought to 180 ° C. The digestion is continued until per chloric acid will smoke. Subsequently 3 drops of nitric acid and heating is continued until the formation of dry salt. The tube walls are washed out and from top to bottom with deionized water (2-5 ml). Subsequently was added 1 drop of 8% aluminum chloride to remove the interference due to phos-

phate. The tubes were then placed in boiling water for 5 minutes. Then removed and cooled and diluted with 12.5 ml of distilled water. After centrifugation 2 ml of the supernatant will aliquots to each tube. The readings were made with a spectrophotometer absorbance 510-580 nm adjusted to room temperature.

To each patient with cirrhosis and upper gastrointestinal bleeding and to each patient in the control group were determined in addition hematological and biochemical profile.

For analysis data were expressed as mean ± standard deviation. When the data presented the Gaussian distribution, parametric tests were used (Student´s t- test for differentiating of avearages and Pearson´s test correlation coefficient). When data did not have the Gaussian distribution, nonparametric tests were used (Wilcoxon´s test for comparing populations and Spearman´s correlation coefficient) and *p* values less than 0,05 were regarded as statistically significant. Statistical analyses were performed using MedCalc software and SPSS 17.0.

RESULTS

Our study enrolled 60 patients with liver cirrhosis complicated by variceal bleeding presented in the emergency unit with mean age 57.32 ± 9,630 (SD), 41 (68,3%) male and 19 (31,7%) female. The control group included 35 patients with mean age 56.89 ± 11.177 (SD), 20 (57,1%) male and 15 (42,9%) female (tab. I).

In our study we assessed the severity of liver cirrhosis using Child-Pugh-Turcotte (CPT) classification. 30% (18 patients) of patients with liver cirrhosis and variceal bleeding were included in class A, 45% (27 patients) class B and 25% (15 patients) class C. 46,66% patients had alcoholic cirrhosis, 25% viral etiology of cirrhosis and 28,33% with both alcoholic and viral etiology. 73,33% patients was portal hypertension (tab. I).

Hematological and biochemical parameters of patients included in our study statistically significant ($p < 0,001$) (tab. II).

Normal values for divalent cations: $Cu2+$=0.8-1.5mg/l, $Zn2+$ =0.8-1.4mg/l, $Mg2+$ = 16-26 mg/l, $Ca2+$= 8.40-10.20mg/l.

The concentration of magnesium was significantly lower between patients with liver cirrhosis (11,682 mg/l ± 2,77) and group control study (14,614 mg/l ± 4,57) (fig.1). Statistical analysis showed correlation between serum levels of magnesium based on the Child-Pugh class (class C) ($p <0.01$, r-0.803) and the presence of other complications like ascites ($p <0.01$, r-0.557) (tab. III, fig. 2).

Serum concentrations of zinc were decreased (0,6815 mg/l ± 0,40 DS) in patients with liver cirrhosis and variceal bleeding, especially in patients with decreased levels of serum total protein ($p<0,01$, r +0.695) and serum albumin ($p<0,01$, r +0.895). Also, there was a statistically significant correlation between decreased levels of zinc and increased value of MCV (mean cell volume) ($p <0.05$, r – 0.323) and GGT (gamma glutamyl transpeptidase) ($p <0.05$, r – 0.285), this indicates a possible correlation between decreased serum levels of zinc and alcohol intake (tab. IV).

Serum levels of copper were increased (1,7365 mg/l ± 0,60 DS) in patients with liver cirrhosis and variceal bleeding and were statistically correlated with serum levels of total protein (r -.433) and albumin (r -.631) in cirrhotic patients with variceal bleeding ($p < 0,01$) (tab. V).

TABLE I

Demographic data of patients in both study groups.

Parameter	Cirrhosis and variceal bleeding	Control group
Age	57.32 ± 9.630	56.89 ± 11.177
Sex Male	 68,3%	 57,1%
Background Urban	 51,67%	 62,86%
Body Mass Index (BMI)	46,67% normal weight	48,15% normal weight
Smoker	53,33%	54,33%
Alcohol intake	70,27%	37,1%
Diabetes history	29,5%	22,9%
High BP history	41,33%	37,67%
Other diseases - Cardiovascular - Asthma	 21,33% 3,66%	 18,66 5,33%
Etiology - alcoholism - viral infection - alcoholism + viral infection	 46,66% 25% 28,33%	 -
Child-Pugh-Turcotte (CTP) Clasification Class A Class B Class C	 30% 45% 25%	-
Portal hypertension	73,33%	-

DISCUSSION

Mechanisms linked on ethanol metabolism, especially oxidative stress, redox potentials and acetaldehyde, participate in the emergence of liver damage. Trace elements play an important role in oxidative stress and redox potentials. A possible role of zinc, copper, and magnesium in pathogenesis of liver cirrhosis and its complications is still subject of researches.

Serum Mg levels were statistically significantly lower from the values of the control groups, the results were in contrast to Rahelić study (7). Studies by Kosch (8) showed decreases in Mg concentration in cirrhotic patients with encephalopathy manifests in relation to serum levels of Mg in patients with steatosis or control groups. Our data are in agreement with the results of Rochhi et al. (9) and Kar et al. (10) which showed a significantly lower level of magnesium in patients with cirrhosis. The same results were observed for Suzuki research (11). The study in our group of patients showed the presence of statistical correlation ($p < 0.01$) between decreased serum magnesium based on Child-Pugh class (Class C) results highlighted in the review by Wang (12) but without differences in the studies performed by Rahelić (7), Moscarella (13).

Our research showed statistically significant correlation between decreased serum zinc levels and decreased serum levels of total protein and albumin. Also, we showed statistically significant correlation ($p < 0.05$) between decreased levels of zinc and increased value of MCV and GGT, this indicated a possible correlation between decreased levels of zinc and alcohol intake. Thus, studies of Kugelmans explain the reduction of plasma levels of Zn due to protein restriction, gastrointestinal and urinary losses (14). Research by Celik noted decreased levels of zinc in serum and ascites fluid in cirrhotic patients (15). The reduction of zinc in serum in patients with liver cirrhosis induced by hepatitis B virus

has been reported by Gur et al. (16). Observations of Lin et al. (17) and of Grungreiff (18) show that serum zinc levels were lower in cirrhotic patients compared to subjects in the control group.

The interaction between zinc and copper in their intestinal absorption and their competition for binding sites on the carrier proteins and cellular uptake may be regulators of their homeostasis. Maybe this can explain inverse concentrations of zinc and copper**.** Zinc binds on albumin, transferrin and metalloproteins in the cell, so relative concentrations of these proteins might regulate the serum concentration of zinc (15).

CONCLUSIONS

Our data showed that in patients with liver cirrhosis and variceal bleeding occurs changes in serum concentrations of divalent cations such as magnesium, zinc, copper and these imbalances should be corrected.

The correction of trace elements concentrations might have a beneficial effect on complications and maybe progression of liver cirrhosis. It would be recommendable to provide analysis of trace elements as a routine. We propose that replacements of those trace elements at an early stage of cirrhosis can delay or prevent the severe outcome in this patients.

CLINICAL STUDY CONCERNING THE EVALUATION OF ANTI-INFLAMMATORY EFFETS OF *CURCUMIN GEL* AS AN ADJUNCT TO SCALING AND ROOT PLANING

The complete removal of irritants is not possible using the mechanical therapy alone. Adjunctive use of systemic administration of antibiotics results in the distribution of drug throughout the body, which can give rise to toxicity. *Curcumin* is a constituent of Curcuma longa plant and possess different properties (anti-oxidant, anti-inflammatory, anti-carcinogenic, anti-microbial, anti-hyper-algesic and hypo-cholesterolemic). A study realized by a group of indian researchers aimed to compare the effects of the *Curcumin* (diferuloylmethane) *gel* as an adjunct to subgingival scaling and root planning with the effect achieved using subgingival scaling and root planning alone. In the study were included thirty patients, either male or female, aged between 25-60 years, with chronic localized / generalized periodontitis, with pocket depth of 5-7 mm affecting at least two nonadjacent sites. In the experimental site scaling and root planning was performed, followed by placement of the *Curcumin gel* and periodontal pack application. In the control site, subgingival scaling alone was performed followed by periodontal pack application. The parameters (Plaque index, Gingival index, Probing depth and Clinical attachment loss) were recorded on day 0, 30 and 45 days. A significant reduction in mean was observed in Plaque index, Gingival index, Probing depth and gain in Clinical attachment level were demonstrated in both the groups from baseline to 45 days. Statistical significant reduction was observed in Plaque index at baseline and 30(th) day and Gingival index at 30(th) day. The conclusion of the study indicate that Curcumin can be effectively used along with scaling and root planning (Anuradha BR, Bai YD, Sailaja S, Sudhakar J, Priyanka M, Deepika V. Evaluation of Anti-Inflammatory Effects of Curcumin Gel as an Adjunct to Scaling and Root Planing: A Clinical Study. *J Int Oral Health.* 2015 ;7 (7) : 90-93).

ECOSOCIAL EPIDEMIOLOGY: MODERN TRENDS IN PREVENTIVE MEDICINE

ECOSOCIAL EPIDEMIOLOGY: MODERN TRENDS IN PREVENTIVE MEDICINE (Abstract) Each of the structural factors of the environment, national and social, interact with each other within the human ecosystem. The dynamic ecosystem changes and transformations determine the nature of the effect on the structures and functions of human body. Knowledge of these ecosystem-derived effect and their sanogenetic or nonsanogenetic particularities in the major objective of Healthy People Medicine (HPM) based on the interative concept of eco-socio-epidemiology. **Keywords**: ECOSOCIAL, ECOSYSTEM, TRANSFORMATIONS, ECO-SOCIO-EPIDEMIOLOGY

Throughout its existence, man directed efforts towards natural and social environmental change for the benefit of improving his life. In these circumstances, the issue of human and human-environment relationships has become increasingly complex, full of benefits but also of nonsanogenetic factors.

Each of the structural factors of the environment, natural and social, interact with each other within the human ecosystem. In this system, man is subjected to the action of various factors and at the same time he influences them so that the human ecosystem is in constant transformations.

The dynamic ecosystem changes and transformations determine the nature of the effects on the structures and functions of the human body.

Knowledge of these ecosystem-derived effects and their sanogenetic or nonsanogenetic peculiarities is the major objective of *Healthy People Medicine* (HPM) based on the integrative concept of eco-socio-epidemiology.

As humans became more numerous and advanced, the self-regulating mechanisms in the ecosystem began to record important failures, endangering human health and life. This lead to dangerous imbalances in the relationships between humans and their working and living environment and ecosystem structures.

The technical and scientific revolution, as well as civilization, is at first sight responsible for the human health hazards through biological, chemical and physical pollution. In reality, man is the true culprit, as in his relations with the ecosystem structures he ignored the rules governing the interrelations between them, their dynamic but very sensitive equilibrium.

The development of the concept and concerns of preventive medicine and later of HPM required population-based approaches to health and disease problems. Thus, an integrative approach to ecology, epidemiology and sociology became necessary.

HPM promotion cannot be conceived without resorting to ecological, socio-

logical and epidemiological methods and methodologies because health protection requires the detection and neutralization of aggression factors both from the natural and social environment. So HPM includes concerns of medical ecology, sociology and epidemiology. Thus HPM benefits from the contribution of a new discipline, eco-socio-epidemiology, born of interdisciplinarity.

The integrative approach of the three components of global human ecosystem (nature, society and people) is only possible by the associative use of the ecological, sociological and epidemio-logical methods and methodologies. To this is added, as a logical necessity, the cooperation of many other medical and non-medical scientific disciplines.

The activities promoted by *Ecosocial epidemiology* can ensure harmonious and balanced human relations with the ecosystem, with favorable consequences for population health promotion.

The epidemiological processes of diseases affecting human populations occur, develop and present features expressing the nature of human-natural environment and human-social environ-ment relationships.

The epidemiological process consists of factors derived from the natural, social and biological components of the human ecosystem, each representing a distinct category, with a particular role in producing morbid manifestations in population.

Ecosocial epidemiology determines which habitat types are health promoting so that in perspective to ensure human survival. It also highlights the risks at the level of habitats, sub-ecosystems and global human ecosystem through pollution, degradation of the quality of air, water, soil, food and lifestyle, including many non sanogenetic components (nutritional, sedentarism, smoking, alcoholism, drug addiction).

Ecosocial epidemiologic research showed that the changes in the human ecosystem due to technical and scientific revolution are reflected in the emergence of new and diverse sources of aggressive agents for health, ways and means of their spreading into the population and various behaviors of the human body.

In these circumstances, epidemiological processes, especially in non-communicable diseases, have become complex, heavily dependent on natural and social conditions and on changing human biology.

Ecosocial epidemiology plays a fundamental role in HPM as it identifies and capitalizes the factors that can contribute to health promotion, while detecting and neutralizing the non sanogenetic factors derived from the human ecosystem structures.

The complex analysis of the phenomena in the social and natural environment that condition health requires studies on the interconnections between health status and the assembly of human relations with the ecosystem, based on an integrative concept offered by ecology, sociology and epidemiology.

Population health status

Ecosocial epidemiology allows us to know all man-man, man-nature, man-society phenomena and connections, focusing on a global view on population health status as a vital whole integrated in a given society, in particular temporal and spatial conditions.

Integration of phenomena which influence the population health status among the social and natural phenomena is essential for successful disease prevention and control actions and promotion of mental and physical health.

Often, in disease prevention and control the socio-economic factors are decisive, and solving the health problems must overcome economic interests related to correction or even change of some technologies or location of economic units generating risk factors for health. In such situations, social epidemiology brings scientific arguments to support the development of prevention measures. Thus, epidemiology detects and evaluates the risk of some environmental factors, highlighting their effects on populations. It also elucidates the inter relationships between the adaptive capacity of human body and the intervention of some social and natural environmental factors.

As part of its main concerns, epidemiology seeks to discover and explain the incidence of diseases in different human ecosystems. To this end, it provides knowledge of the characteristics of factors that constitute the epidemiological process: factors-host (human-individual variables); factors-agent (disease-bearing variable), factors-natural and social environment (where host factor and agent interact).

The study of the structure and evolution of epidemiological processes by social epidemiology demonstrated the role of social factors. These factors can cause or favor a predisposition to disease, can directly cause a disease state, can transmit the disease causes and can influence the natural progression of disease.

Epidemiological research on the different structures of the human ecosystem reveal or suggest an etiological hypothesis, identify and rank the factors that may cause the emergence and evolution of disease at population level.

CONCLUSIONS

By the large arsenal of methods adequate for population-based studies epidemiology together with ecology and sociology can detect the significant correlations between health or disease status and the factors generated by intrapopulational relationships and between these and the human relationships with the natural and social environment.

In these circumstances, the contribution of *Ecosocial epidemiology* to the development and implementation of health promotion and disease prevention and control programs becomes essential.

These programs provide evidence of the epidemiological, ecological and sociological causal determinism of the health or disease status.

The complex mechanisms of action of biological,physico-chemical, technological, nutritional, educational, psycho-emotional and other factors acting on a determined genetic background are evaluated.

Epidemiology, promoting ecological and sociological concepts in the evaluation of health and disease phenomenon, demonstrates that disease prevention cannot be achieved solely by medical effort, but as a complex process with wide temporal and spatial extension, which should protect individuals from the prenatal period until the end of life.

ADVANCED AGE AND INCIDENCE OF ATRIAL FIBRILLATION IN THE POSTOPERATIVE PERIOD OF AORTIC VALVE REPLACEMENT

Postoperative atrial fibrillation (AF) is the most common complication after cardiac surgery and is associated with higher risks of cerebrovascular accident (CVA), hospital expenses and mortality as well as longer hospital and Intensive Care Unit (ICU) stay. In most cases, it spontaneously reverts to sinus rhythm, without the need for pharmacological intervention. Postoperative AF occurs in approximately 30% to 40% of patients who undergo coronary artery bypass grafting (CABG) and in up to about 60% of patients who undergo concomitant valve surgery. The incidence of this arrhythmia depends on the definitions adopted, the characteristics of the patients, the type of surgery performed, and the monitoring method. AF incidence has been increasing for the past few decades thanks to the higher percentage of elderly patients undergoing cardiac surgery. This arrhythmia occurs typically on the second or third postoperative day, with 70% of the events occurring by the fourth day. However, it can happen at any time after surgery, including after hospital discharge. In fact, AF is the leading cause of early hospital readmission after cardiac surgery. Indications for aortic valve surgery have been increasing due to an increase in population longevity. Even though AF is expected to be more frequent, there are few data on the prevalence of this condition in individuals aged 80 years or older and on its correlation to morbidity and mortality to offer guidance on the possible need for more aggressive prophylaxis during the preoperative period of more elderly patients. In this study was analyzed a sample of elderly patients and described the correlation between age and occurrence of acute postoperative AF after aortic valve stenosis surgery. Secondly, it set out to assess the influence of AF in the incidence of postoperative CVA, hospital length of stay, and hospital mortality (Fernando Pivatto Júnior1, MD; Guaracy Fernandes Teixeira Filho1, MD; João Ricardo Michelin et al. Advanced age and incidence of atrial fibrillation in the postoperative period of aortic valve replacement. *Rev Bras Cir Cardiovasc* 2014; 29(1): 45-50).

ETHICAL MODELS OF PHYSICIAN – PATIENT RELATIONSHIP REVISITED WITH REGARD TO PATIENT AUTONOMY, VALUES AND PATIENT EDUCATION

Liana Rada Borza[1*], Cristina Gavrilovici[1], René Stockman[2,3]

ETHICAL MODELS OF PHYSICIAN – PATIENT RELATIONSHIP REVISITED WITH REGARD TO PATIENT AUTONOMY, VALUES AND PATIENT EDUCATION (Abstract): The present paper revisits the ethical models of patient – physician relationship from the perspective of patient autonomy and values. It seems that the four traditional models of physician – patient relationship proposed by Emanuel & Emanuel in 1992 closely link patient values and patient autonomy. On the other hand, their reinterpretation provided by Agarwal & Murinson twenty years later emphasizes the independent expression of values and autonomy in individual patients. Additionally, patient education has been assumed to join patient values and patient autonomy. Moreover, several authors have noted that, over the past few decades, patient autonomy has gradually replaced the paternalistic approach based on the premise that the physician knows what is best for the patient. Neither the paternalistic model of physician – patient relationship, nor the informative model is considered to be satisfactory, as the paternalistic model excludes patient values from decision making, while the informative model excludes physician values from decision making. However, the deliberative model of patient – physician interaction represents an adequate alternative to the two unsatisfactory approaches by promoting shared decision making between the physician and the patient. It has also been suggested that the deliberative model would be ideal for exercising patient autonomy in chronic care and that the ethical role of patient education would be to make the deliberative model applicable to chronic care. In this regard, studies have indicated that the use of decision support interventions might increase the deliberative capacity of chronic patients. **Keywords**: PATIENT AUTONOMY, PHYSICIAN – PATIENT RELATIONSHIP, PATIENT EDUCATION, CHRONIC DISEASES

Autonomy has emerged as a central concept in contemporary health care ethics (1, 2).

In 1981, Miller (3) proposed four senses of autonomy in medical ethics, as follows: autonomy as free action – an action that is voluntary and intentional; autonomy as authenticity – an action is consistent with the person's dispositions, values and life plans; autonomy as effective deliberation – the person is aware of and evaluates both the alternatives and their consequences,

choosing an action based on this evaluation; autonomy as moral reflection – acceptance of the moral values one acts on, as one has reflected on these values and accepts them as his/her own.

Studies have regarded patient autonomy and values to be key variables in the ethical models of patient – physician interaction. Values can be defined as the beliefs or principles of a person, which are used to guide decisions and way of life (4, 5).

It has also been highlighted the importance of good patient – clinician relationships for the ethical principle of respect for autonomy, as supportive relationships can be more facilitative with regard to patient capability for autonomy than concern to allow patient independence (6). Moreover, cancer research has indicated that constructive patient – physician relationships are considered to be essential to minimize disease – related stress and anxiety (7). Additionally, patient education has been increasingly recognized as a method for optimizing treatment of chronic diseases (8).

Thus, the objective of the present paper would be to revisit the ethical models of patient – physician relationship from the perspective of patient autonomy, values and patient education.

PATIENT AUTONOMY, VALUES AND PATIENT EDUCATION IN PATIENT – PHYSICIAN INTERACTION

In 1992, Emanuel & Emanuel (4) outlined the four traditional models of physician – patient relationship. The paternalistic model, where the physician independently decides, assumes that the patient has low health – related values formation, the model being characterized by low patient autonomy and low information disclosure by the physician. In the interpretive model, the physician provides patients with pertinent information and helps them to elucidate their values, but it is the patient who ultimately decides. The deliberative model allows the physician to guide the patient's decision making and the patient to deliberate on the differences between his or her preferences and the ones of the physician. The informative model, where the patient alone takes on decision making responsibilities, presupposes that the patient possesses well known and fixed values, this model being characterized by high patient autonomy and high medical information delivery to the patient (5, 9).

It has been noticed that the models described by Emanuel & Emanuel tightly link patient values and patient autonomy by assuming that, as patient autonomy increases, the strength and formation of patient values should increase as well. However, twenty years after the publication of the paper of Emanuel & Emanuel on the four models of the physician – patient relationship, Agarwal & Murinson (5) proposed a reinterpretation of these traditional models. The reinterpretation draws attention to the independent expression of values and autonomy in individual patients (e.g. the patient with high autonomy, but low formation of health – related values) and adds patient medical knowledge as a new dimension in the patient – physician interaction. In this regard, while the traditional models of patient – physician relationship involve a unidirectional flow of medical information from physician to patient, the reinterpretation of these models also takes into consideration the growing availability of medical information accessible to the general public via the internet.

In addition, patient medical knowledge is supposed to join patient values and patient autonomy.

Furthermore, several papers underline that, over the past few decades, there has been a shift from a paternalistic approach to patients towards an emphasis on patient autonomy (10, 11, 12, 13).

However, it has been suggested that good patient care might involve a closer look at some remaining aspects of paternalism (11). In this regard, it has been revealed that paternalism should still have a role in decision making, if we consider that there are physicians who avoid making difficult medical decisions by hiding behind the respect for patient autonomy (14). On the other hand, studies indicate that the number of physicians who believe in paternalism as a form of beneficence is still significant (15). Moreover, even though patient expectations and desire to be implicated in treatment decisions are increasing, some patients still prefer to leave decision making to their physician (7). Another study has also noted that there are many patients who would prefer a paternalistic approach (16). In addition, there has been outlined that the so-called modern paternalism takes into account patient values and interests, but considers these values as only one factor among others, whereas autonomy refers to patient values as decisive (17). In any case, several authors indicate that the balance between autonomy and paternalism needs reassessment in such a way that beneficence and autonomy would be mutually reinforcing rather than competing (14, 18, 19, 20).

If the four traditional models of the physician – patient relationship would be represented as a single linear axis, the paternalistic model and the informative one would be the two extremes of the axis, neither of the two being satisfactory with regard to decision making approach (4, 5, 10, 21). The informative model, also known in the literature as the independent choice model, reflects a defective understanding of patient autonomy, as it sacrifices physician competence for patient control. In this model, physicians withhold their recommendations and experience and carry out patients' decisions. Such a model presumes that if the patient is to gain power to make autonomous choices, the physician has to lose power (4, 10). Nevertheless, it is suggested that such overemphasis on patient autonomy may suppress beneficent intervention (19).

Therefore, the paternalistic model leaves the patient outside the decision making process, while the informative model leaves the physician outside by reducing the role of the physician to that of a technician providing the chosen service (2, 4, 22).

The deliberative model offers a better alternative to these unsatisfactory approaches, because, in this model, both physician and patient engage in moral deliberation and the patient considers through open dialogue alternative health – related values. Thus, the deliberative model promotes shared decision making and negotiation between the physician, who has a caring attitude, and the patient, being recommended as the best model for the physician – patient relationship and for exercising patient autonomy (2, 4, 9). Shared decision making has also been increasingly regarded as an ideal model of physician – patient interaction, in which both the patient and the physician make active and essential contributions through open dialogue, joint deliberation and mutual understanding (4, 22, 23). An analogous model based on

mutual understanding, described in the scientific literature as an authentic interaction between physician and patient, is the dynamic and genuine dialogue – based model of autonomy, which also reflects a care giving relationship and overcomes the imbalance of power that is present in both paternalistic and informative models with regard to decision making (11). Additionally, the enhanced autonomy model underlines that the physician guides the decisions of the patients in a way that allows patients to exercise autonomy more powerfully if they make decisions that integrate the experience of the physician with their own. Hence, this model promotes, similarly to the deliberative model, to the shared decision making model and to the dialogue – based model, a physician – patient relationship characterized by open dialogue and mutual influence and understanding, where patient and physician share power, negotiate differences and actively exchange ideas (10).

Moreover, in 2014, by revisiting the four traditional models of patient – physician relationship, Reach (9) proposes a model of care in chronic diseases based on patient education, pointing out that the ethical role of patient education would be to make the deliberative model applicable to chronic care and, thus, to give patients the opportunity to exercise autonomy in an ideal situation. In this regard, patient education is referred to as an ethical pathway that links three of the four models of physician – patient relationship, as follows: the physician first gives the facts (the informative model), helps the patients to elucidate their preferences (the interpretive model) and finally gives them the opportunity to choose between their preferences and the ones of the physician, so that the deliberative model can be reached at the end of this pathway.

Studies on decision making in cancer patients have emphasized that the distress experienced during the time of diagnosis might diminish the deliberative capacity of a patient (24). In this regard, it has been pointed out the contribution of decision aids in cancer care, as decision aids are described to be decision support interventions designed to teach patients the deliberative skills needed to negotiate their way through relevant information, to clarify their values and to guide them in the steps of decision making and communicating with others (25, 26).

In order to promote respect for autonomy of patients with chronic life-threatening diseases, it has been revealed that such patients should be encouraged to have a values discussion with their physician and to document the values and goals that should guide future decisions. As values can change, values discussions should be revisited occasionally, especially when patient condition changes significantly. In this regard, it has been emphasized that the physician should recommend the medical means to honor those values and achieve those goals (27).

CONCLUSIONS

To conclude, patient autonomy, patient values and patient education are referred to as central variables in the models of physician – patient interaction.

The deliberative model, the shared decision making model, the dialogue – based model of autonomy and the enhanced autonomy model are recommended to be the best for the physician – patient relationship and for exercising patient autonomy, and, in our opinion, they appear to express, under different names, the same model of

physician – patient relationship. Such a model, which is based on open dialogue, joint deliberation and mutual understanding, would be the balanced alternative between the two extremes represented by the paternalism and the informative model, as it overcomes the imbalance of decision making power between patient and physician.

Moreover, the deliberative model has been suggested to be ideal for exercising patient autonomy in chronic care. Studies have indicated that the use of decision aids could increase the deliberative capacity of chronic patients. In addition, it has been pointed out that, in order to promote respect for autonomy of chronic patients, discussions that elucidate patient values should be occasionally revisited.

NEWS

FIBROMUSCULAR DYSPLASIA OF CARDIAC CONDUCTION SYSTEM ARTERIES IN TRAUMATIC AND NONNATURAL SUDDEN DEATH VICTIMS

In several reports, luminal narrowing by fibromuscular dysplasia of the sinus and/or AV-node artery was found in examinations of unexplained deaths and, in many cases, was considered as the cause of death. These reported cases were aged between 0 and 49 years; both sexes were affected. However, there are no data on the frequency of fibromuscular proliferations of arterial walls in heart healthy control groups. But, the exact cause of these fibromuscular vessel alterations is still unclear. Possible hypotheses might be either the consequence of the impact of the bloodstream on small vessel branches or a protective mechanism against luminal extension. Since fibromuscular proliferations of arteries of the cardiac conduction system and small coronary arteries occur in 84% in an obviously heart-healthy control group, these findings should be known to every (forensic) pathologist and anatomist. This might reduce the risk of misdiagnosis. In the same time, the reported results demonstrate that microscopically detectable findings of the cardiac conduction system arteries similar to fibromuscular dysplasia do not indicate a defined disease and should not be considered as a cause of death when there are no macroscopic findings in the coronary arteries (Zack F, Kutter G, Blaas V, et al. Fibromuscular dysplasia of cardiac conduction system arteries in traumatic and non-natural sudden death victims aged 0 to 40 years: a histological analysis of 100 cases. Cardiovascular Pathology 2014, 23: 12–16).

IMIDAZOLINE RECEPTOR ANTAGONISTS IDAZOXAN AND EFAROXAN ENHANCE LOCOMOTOR FUNCTIONS IN RATS (Abstract) Discovered in 1984, imidazoline receptors (I_1, I_2, I_3) are located centrally and peripherally being involved in various physiologic and pathophysiologic processes in the body. Experimental and clinical investigations have suggested the interrelations between imidazoline, adrenergic, dopaminergic, glutamatergic and opioid systems, which may explain the influence of different substances acting on imidazoline receptors in cognitive disorders, behavioral disturbances and motor diseases pathways. **Aim:** To investigate the effects of two imidazoline receptor antagonists on locomotor activity and endurance capacity in rats. **Material and methods:** The experiment was carried out with white male Wistar rats (200-250g) divided into 3 groups of 7 animals each, treated intraperitonealy with the same volume of solution as follows: Group I (Control): distilled water 0.3ml/100 g body weight; Group II (IDZ): idazoxan 3 mg/kbw; Group III (EFR): efaroxan 1 mg/kbw. Exercise capacity was evaluated using a locomotor PanLAB treadmill test. The data were presented as mean +/- standard deviation and significance was tested by SPSS Statistics for Windows version 17.0 and ANOVA method. Experimental protocol was implemented according to recommendations of the Gr.T. Popa" University Committee for Research and Ethical Issues. **Results:** Intraperitoneal administration of idazoxan and efaroxan resulted in a significant increase in running distance compared with the control group ($p<0.05$). At the same time a reduction in the number and time of electric shocks delivered to motivate the animal to keep running was observed. In this experimental behavioral model the effects of idazoxan on the evaluated parameters were more intense than those of efaroxan. **Conclusions:** In our experimental conditions we demonstrated the ability of imidazoline receptor antagonists idazoxan and efaroxan to improve fatigue resistance during forced running in rats. **Keywords:** IDAZOXAN, EFAROXAN, TREADMILL, LOCOMOTOR.

Imidazoline receptors were identified for the first time in 1984, three types being known today: I_1, I_2 and I_3. I_2 imidazoline receptors have been subdivided into two subtypes according to their affinity for amiloride: I_2A subtype is amiloride-

sensitive and I_2B subtype is amiloride-insensitive (1).

Literature data revealed that imidazoline receptors are located centrally and peripherally, being involved in numerous physiological and pathophysiological processes, but the mechanisms are not yet fully understood (2).

Until now four endogenous imidazoline receptors ligands have been characterized, of which agmatine (decarboxylated arginine) is the most known and studied. The others are: two varieties of beta-carbolines: harmine and harmaline and imidazoleacetic acid robotide (3).

Imidazoline receptors have a great affinity for binding to various compounds with imidazolinic structure. Most of the ligands with affinity for imidazoline receptors also bind to alpha-2 adrenergic receptors, these two types of imidazoline receptors being difficult to differentiate (4). Modern methods, such as autoradiography and radio-ligation techniques, offer only indirect evidence regarding the presence of distinct binding sites for alpha-2 and imidazoline receptors (2).

Numerous experimental studies and clinical trials have showed the involvement of imidazoline receptors in different physiologic and pathophysiologic conditions in the body.

- I_1 imidazoline receptors mediate sympathetic inhibitory actions of imidazoline derivatives associated with the decrease of blood pressure (5);
- I_2 imidazoline receptors modulate the level of central monoamines and activate hypothalamic adrenal pituitary axis with a potential antidepressant activity (6);
- I_3 imidazoline receptors regulate insulin secretion in the beta Langerhans pancreatic cells (7).

The potent neurotransmitter agmatine is involved in the mediation of stress response, analgesia, drug addiction, withdrawal syndrome, and in the modulation of seizures development and in neuroprotection (1, 6).

Various experimental and clinical studies suggested the interrelations between imidazolinic, adrenergic, dopaminergic, glutamatergic and opioid systems; thus they might explain the influence of different substances acting on imidazoline receptors on cognitive disorders, behaviour disturbances and in motor diseases pathways. (8, 9) The results reported in the literature are inconsistent and some of them controversial.

The investigations regarding the involvement of substances acting on imidazoline receptors in behaviour, memory, and locomotor activity might lead to new data on the pathophysiological mechanisms of spontaneous behaviour alterations and cognitive disturbances (6, 9).

Idazoxan is a 2-(2,3-dihydro-1,4-benzodioxine-2-yl)-4,5-dihydro-1H-imidazole derivative that selectively blocks alpha-2 adrenergic and imidazoline receptors. Various studies have been performed to investigate its effects in depression, schizophrenia and different types of psychosis, but the results are not yet validated (10, 11). Some recent researches demonstrated the neuroprotective activity of idazoxan with a reduction of blood brain barrier damage during experimental autoimmune encephalomyelitis in mouse (12).

Efaroxan, 2-(2-Ethyl-2,3-dihydro-1-benzofuran-2-yl)-4,5-dihydro-1H-imidazole derivative is an alpha-2 adrenergic receptor antagonist and also an imidazoline receptor ligand (2, 5). In the last few years investigations on the involvement of this imidazo-

line receptor antagonist in the regulation of blood pressure, pancreatic insulin secretion and also in depressive conditions have been conducted (2, 5, 13).

The aim of this study was to investigate the effects of imidazoline receptor antagonists idazoxan and efaroxan on locomotor activity and endurance capacity in rats.

MATERIAL AND METHODS

The experiment was carried on white Wistar rats (200-250g). Animals were housed in plastic cages in an animal room maintained at 23 ± 1°C on a 12-hour dark cycle (light period, 07:00 – 19:00). Standard laboratory food and tap water were freely available, except during the time of the experiments.

Rats were divided randomly into four groups 7 animals each, treated intraperitoneally with a single dose as follows: Group I (Control): distilled water 0.3 ml/100g weight; Group II (IDZ): idazoxan 3 mg/kbw; Group III (EFR): efaroxan 1 mg/kbw.

Idazoxan and efaroxan (purchased from Sigma Aldrich Chemical Co, Germany) were diluted in distilled water and prepared extemporaneously.

Exercise capacity was assessed using a PanLAB treadmill for locomotor-fatigue. This apparatus consists of a rolling belt (driven by a servo-controlled motor) with an adaptable speed and angle profiles, enabling forced exercise training and accurate testing of fatigue in laboratory animals (13, 14). Treadmill System is a fully computerized automatically controlled device designed to assess rodent exercise capacity when forced to run. It is provided with a grid that administers an electric shock (power 700 V Dc at a maximum current of 0.4 mA) that forces the animal to run when it stops and two counters to record the parameters necessary to investigate the physical performance. One counter records the distances and the other the number of electrical shocks received by the animals during the experiment.

In our experiment, rats were trained at a speed of 40 cm/second on a 5 degree tilting of the belt, having run as forced exercise on motorized treadmill 10 minutes sessions.

The locomotors performance of rats was quantitatively evaluated by recording the following parameters: distance run, number of electrical shocks and time of delivering the stimulatory shocks (16).

In this behavioral model of forced exercise, the decreasing of time interval of delivering the electric shocks or the reduction of the number of shocks necessary to motivate the animal corresponds to the endurance-enhancing effect induced by the investigated substance (16, 17). Opposite to this, the increase of time interval for stimulating shock delivery or the number of electric shocks may be correlated with the diminution of physical endurance (17).

On the other hand, the increasing of distance run on the rolling belt may be related to an enhancing of endurance to effort and also to a stimulation of motor activity after substances administration (18, 19). In contrast, the reduction of distance run at the same time interval of the experiment signifies the alteration of animal physical performance in the forced locomotion test (18).

The data were presented as +/- standard deviation and significance was tested using the *SPSS Statistics 17.0* for windows software. Analysis of variance (ANOVA one-way method) and *post hoc* Newman-Keuls and Tukey independent tests were used to determine statistical differences between

the investigated groups. P-values less than 0.05 were considered statistically significant compared to control group.

Experimental protocols were implemented according to the recommendations of the"Gr. T. Popa" University Committee for Research and Ethical Issues. Each animal was used once only and the duration of the experiments was kept as short as possible. For ethical reasons, all the animals were sacrificed at the end of the experiment (20).

RESULTS AND DISCUSSION

The treadmill running test is one of the most frequently used behavioral valuable non-invasive method for assessing the effects of imidazoline receptor antagonists on the locomotor activity and endurance capacity of laboratory animals during physical effort. In addition, the treadmill test was used to clarify the movement motivation of rats (21).

Using the behavioral experimental model of forced locomotion we obtained three types of information regarding the animal physical ability. The following parameters recorded during the 10 minute sessions (distance run, number and delivery time of electric shocks) represent essential tools used to estimate the endurance capacity, and an important modality to corroborate and validate the biological significance of data (14, 22).

During habituation to monitorized treadmill, rats treated with idazoxan (3 mg/kbw) showed a significant increase ($p<0.05$) of distance run (248.17±27.25 meters) compared to the control group (205.75±39.60 meters) (fig. 1).

Intraperitoneal administration of efaroxan 1 mg/kbw lead to an increase in distance run (220.00±19.09 meters), statistically significant ($p<0.05$) compared to the control group (205.75±39.60 meters) in the same behavioral model (fig. 1).

The mean distance run by rats treated with efaroxan was shorter than of rats treated with idazoxan, in the same time interval in the experiment (tab. I).

These results proved the ability of imidazoline receptor antagonists idazoxan and efaroxan to improve fatigue resistance during forced running on this behavioral experimental model.

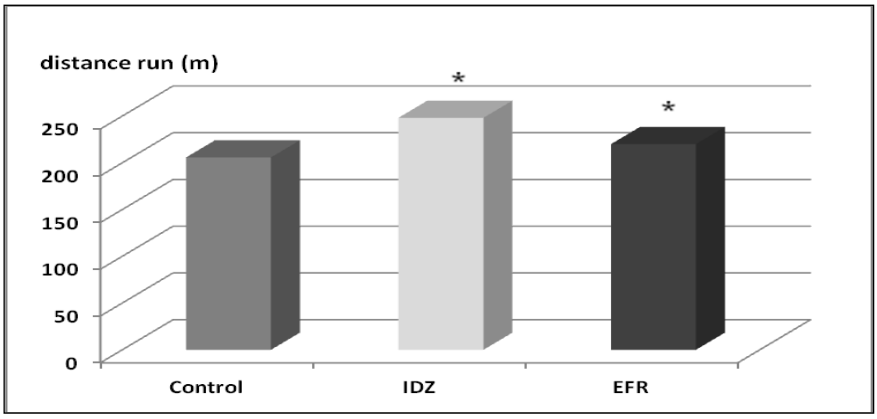

Fig. 1. The effects of idazoxan and efaroxan on distance run in the treadmill exercise test. Each value is the mean ± SEM of distance run (meters) for seven rats. *$p<0.05$, **$p<0.01$ *vs.* control group.

TABLE I
Descriptive statistics – distance run

	N	Mean	Std. Deviation	Std. Error	Min	Max	Sig
Control	8	205.75	39.60	14.00	116.00	233.00	
IDZ	8	248.17	27.25	9.23	163.00	252.00	**0.031***
EFR	8	220.00	19.09	6.75	179.00	239.00	**0.046***

* Mean difference significant at .05 level; ** Mean difference significant at .01 level.

TABLE II
Descriptive statistics – number of electric shocks

	N	Mean	Std. Deviation	Std. Error	Min	Max	Sig
Control	8	96.88	79.90	28.25	26.00	273.00	
IDZ	8	78.36	61.65	31.35	11.00	216.00	**0.039***
EFR	8	85.38	84.59	29.91	6.00	279.00	**0.047***

* Mean difference significant at .05 level; ** Mean difference significant at .01 level.

The administration of idazoxan (3 mg/kbw) was associated with a significant reduction ($p<0.05$) in the number of electric shocks (78.36±61.65) and also in delivery time of shocks (25.28±19.23 seconds) compared to control group (96.88±79.90, 32.64±25.57 seconds respectively) (fig. 2.).

The treatment with efaroxan 1 mg/kbw resulted in a significant ($p<0.05$) decreasing of both electric shocks number (85.38±84.59) and delivery time of shocks (28.59±25.35 seconds) compared to control group (96.88±79.90, 32.64±25.57 seconds respectively) (fig. 2, 3).

The effects of idazoxan on these parameters were more intense than those of efaroxan in the forced exercise test (tab. II, III).

CONCLUSIONS

Our experimental investigation demonstrated clear beneficial effects of both imidazoline receptor antagonists idazoxan and efaroxan on endurance exercise performance.

The intraperitoneal administration of idazoxan and efaroxan resulted in an improvement of physical performance and also of endurance capacity in the forced locomotion experimental model in rats.

These findings prove the ability of imidazoline receptor antagonists idazoxan and efaroxan to improve locomotor abilities and to delay fatigue in rats during forced running on this behavioral experimental model. The effects of idazoxan on the recovery of locomotor activity of rats were more intense than those of efaroxan in the treadmill test.

Much more, using this behavioral experimental model, we demonstrated the valuable effect of idazoxan and efaroxan on the improvement of depression-like behavior in rats.

NEWS

IL-10 AND ET-1 AS BIOMARKERS OF RHEUMATIC VALVE DISEASE

Rheumatic fever (RF) represents a serious public health problem. It is a rheumatic and inflammatory disease of autoimmune origin, which occurs in response to an infection by group A streptococcus. On a global scale, this agent is responsible for approximately 15.6 million annual cases of rheumatic heart disease, with 282,000 new cases and 233,000 deaths each year. From this perspective, health systems face higher expenses with clinical exams, surgeries and frequent hospitalizations due to congestive heart failure. The pathogenesis of RF involves a complex network of genetic, environmental and immunological interactions. Genetic factors predispose individuals to developing autoimmune reactions. Cytokines are proteic molecules, glycosylated or not, that send a range of stimulatory, modulatory or inhibitory signals to the various cells of the immune system. Studies indicate that the inflammatory response in acute RF on cardiac tissues is generated by antigenic mimicry of the protein M leading to an abundant infiltration of CD4+ T cells. This leads to production of inflammatory cytokines (e.g., TNF-α, IL-2, and IL-10), which have a decisive influence on the immune response of patients with rheumatic fever. It is also known that increased levels of Th1 inflammatory cytokines (TNF-α and IFN-γ) and lower levels of Th2 and regulatory cytokine IL-4 lead to maintenance and progression of rheumatic valvulopathy. Endothelin is a highly potent vasoconstrictor peptide. This peptide is composed of 21 amino acids and has three isoforms. The three isoforms are called endothelin-1 (ET-1), endothelin-2 (ET-2) and endothelin-3 (ET-3). Endothelin-1 is the subtype predominantly produced by cardiac endothelium. Some studies show gene expression of endothelin in heart valves of patients who underwent surgical valve replacement. Cardiac involvement in acute RF characterizes the most serious and most important of all manifestations of the disease because of the possibility of progressing to chronic rheumatic valvular disease or death. The most common rheumatic mitral valvulopathy is a dual unbalanced dysfunction, i.e, insufficiency and stenosis in different stages of development, which may lead to an indication of surgical repair or replacement of the damaged valve in children and young people in productive age. In this study were compared the levels of some interleukins (TNF-alpha, IL-4 and IL-10) among different patients with RF. In addition, was assessed gene expression of endothelin-1 in native replaced mitral valves (Leão SC, MD; Menezes Lima MR, Menezes do Nascimento H, et al. IL-10 and ET-1 as biomarkers of rheumatic valve disease. Rev Bras Cir Cardiovasc 2014; 29 (1): 25-30).

GC-MS ANALYSIS OF *MALUS DOMESTICA* BARK AND LEAF EXTRACTS IN PESTICIDE NON-EXPOSED AND EXPOSED MATRICES (Abstract): **Aim:** Research on phytochemical constituents' existent in *Malus domestica* leaves and bark is a nowadays topic of interest especially due to the presence of various secondary metabolites with potential pharmacological characteristics. Quantifying the residual levels of singular pesticides, e.g. tebuconazole, and/or of chemicals in clearly stated combinational formulations is also of great interest especially due to all negative effects induced by pesticides on human health. **Material and methods:** The strategy within the present study corroborates field activities (i.e. clear treatment scheme, leaf and bark samples collection from the *Golden Delicious* and *Jonathan* apple varieties from an orchard in Miroslava, Iasi, Romania, before and after treatments spread) with sample analysis by gas chromatographic methods. Ultrasound-assisted techniques and clean-up procedures were used during the preparative steps. All methanol (MeOH) extracts were analyzed using a gas chromatograph, Agilent 7890A, in tandem with a mass spectrometer, Agilent 5975C, Agilent Technologies, United States of America. **Results:** Analysis of the chromatographic profiles obtained for the investigated pesticide non-exposed matrices revealed the existence of many potential therapeutic bioactive compounds with positive benefits on human health (e.g., lupeol, friedelin, α-tocopherol known also as vitamin E, mellein). Chromatographic run profiles of methanol extracts associated to sample matrices collected at different periods within the treatment scheme revealed the existence of the chromatographic peak corresponding to tebuconazole at a retention time of 13.75 minutes. Pesticides existent in the in-use clearly stated combinational formulations have been as well identified. **Conclusions:** A preliminary characterization of the secondary metabolites existent in *Golden Delicious* and *Jonathan* apple leaves and bark was achieved for the first time for samples collected from an orchard in Miroslava, Iasi, Northeastern Romania. In pesticide non-exposed matrix compounds of pharmacological interest have been identified. Clear evidence has been obtained about the existence of tebuconazole and of other pesticides from the in-use clearly stated combinational formulations, in all samples collected in a well-established time span from the treatment spread. Samples containing residual pesticides might induce possible negative consequences for human health. **Keywords:** TEBUCONAZOLE, *JONATHAN*, *GOLDEN DELICIOUS*, LEAF, BARK.

In temperate geographic areas apple tree is one of the most widely cultivated fruit trees (1). Apples, as rich sources of phytochemicals, are the fruits extensively used worldwide (2).

Minerals such as nitrogen, phosphorus, potassium, calcium, magnesium, iron, copper, manganese, zinc are present in important amounts in apple leaves (3). Apple leaves and bark are often assigned as potential sources of antioxidant compounds (4,5,6). Flavonoids and other phenols from plants, such as phenolic acids, stilbene, tannins, lignans and lignin, are particularly common in leaves, flowers and woody tissues, such as stems and bark (7).

Nowadays, tebuconazole (TEB) which is a systemic triazole fungicide is intensively used to combat foliar diseases in fruit trees (8). This triazole fungicide group inhibits lanosterol 14∝-demethylase (CYP51) activity by disrupting pathogen's membrane and by inhibiting pest's cells growth. It has been already shown that tebuconazole is highly efficient against pathogenic fungi from various plants and that it is widely used for controlling white rot disease. Important quantities of apple are exported from China (9) to Europe (10), and studies performed in field on Chinese crops have shown that tebuconazole is an excellent fungicide for controlling white apple rot (9). There are studies suggesting that tebuconazole is highly efficient in combating mold and rust in fruit, and that once these tebuconazole-containing fruits are consumed they can exert serious health consequences (11).

MATERIAL AND METHODS

Treatment and sampling. Clearly stated combinational pesticide formulations, containing mainly tebuconazole, were used during sample treatments. The interest products have been sequential sprayed (4 times) in full agreement with the producer's recommendation (Bayer) and the samples (leaves, bark) have been collected by following an own developed strategy in the April 9, 2016 – October 6, 2016. No significant precipitation events have been recorded during treatments and sampling steps, Iasi region facing mainly drought throughout the period of interest.

Sample preparation. Samples collected from two varieties of apple, i.e. *Golden Delicious* and *Jonathan*, were subjected to several preparative steps for further analysis by GC-MS technique. Accurately weighted amounts from each matrix of interest, whether or not previously subjected to field treatment with tebuconazole and clearly stated combinational pesticide formulations, each in normal and double dose, were passed through ultrasound assisted extraction process in two different solvents.

To increase extraction efficiency and the requested accuracy for a specific study on pesticide dynamics in the field, each sampled matrix was well shredded with a scalpel. This step was immediately followed by mass weighing on an analytical balance Adam PW254 with an accuracy of 10^{-4} g. For each matrix ~ 0.2 g of sample was weighed (i.e. *Golden Delicious* and *Jonathan* matrices, two modes of treatment, singular tebuconazole and with clearly stated combinational pesticide formulations, each at normal dose and double dose, at each collection point).

Each weighed sample mass placed in an Eppendorf tube was treated with 3 mL of solvent. For the ultrasound assisted extraction procedure two solvents were initially used, i.e. methanol (MeOH) and acetoni-

trile (ACN). Later, MeOH was preferred due to its higher extraction efficacy. After adding the solvent, the samples were subjected to the ultrasound-assisted extraction process in an Elmasonic S70H ultrasonic bath for 45 minutes (3 cycles × 15 minutes), which has been proven to suffice a good extraction yield and not to aggressively degrade the chemical composition of the extract (12). After this step, the Eppendorff units containing the samples extracted into methanol (MeOH) were coated with aluminum foil and allowed to stand in the dark for 24 hours. Immediately after, the Eppendorff units containing the samples were centrifuged for 5 minutes at 5000 rpm at a temperature of 40°C using a Hettich Universal 320R centrifuge. Each generated supernatant was transferred with dedicated Pasteur pipette into new Eppendorf tubes. The obtained extracts were subjected to specific drying procedures using the principle of solid phase extraction (SPE). Homemade cartridges filled with anhydrous sodium sulphate (Na_2SO_4 anh.) and glass wool as stopper were used to dry each obtained extract. The extracts thus generated were passed through Pall Acrodisc PSF, G×F/GHP filters of 0.2 μm porosity. Volumes in the 1-2 mL range were transferred into brown vials and then stored in the refrigerator (4^oC) until the analysis.

Sample analysis. Analysis of the entire set of samples was performed on the GC-MS system at the CERNESIM Center, Integrated Center of Environmental Science Studies in the Northeastern Region, at the "Alexandru Ioan Cuza" University of Iasi, Faculty of Chemistry, Analytical Chemistry Laboratory. Samples were manually injected with a micro syringe into a gas chromatograph, 7890A GC model from Agilent Technologies, equipped with flame ionization detector (FID) and a mass spectrometer 5975C MS model from Agilent Technologies, USA.

For sample analysis the optimized working conditions of the equipment were: 1) helium as mobile phase; 2) capillary column HP-5ms type (30 m length, 0.25 mm internal diameter and 0.25 μm film thickness) as a stationary phase; 3) 270 °C operating temperature of the injector; 4) 0.003 mL injected volume under spitless conditions; 5) temperature gradient with the following steps: 60 ˚C for 1 minute, ramp with 30 ˚C/min. up to 220 ˚C (0 min.), followed by a ramp of 2 ˚C/min to 240 ˚C, constantly 4 minutes, followed by a ramp of 10 ˚C/min to 290 ˚C (constant 10 min.) 6) 230 °C MSD temperature; 7) 150 ˚C quadrupole unit temperature; 8) full scan mode for acquisition of mass spectra; 9) scanned mass range m/z 60-650 atomic mass units; 10) ChemStation, Agilent Technologies soft keys and NIST database for data analysis.

RESULTS

Gas chromatography tandem mass spectrometry (GC-MS) has been used for the analysis of the non-exposed and exposed pesticide matrices. In the phytochemical constituents of both *Golden Delicious* and *Jonathan* matrices, tebuconazole and pesticides present in clearly stated combinational pesticide formulations have been identified upon the sample state, i.e., pesticides non-exposed and exposed matrices.

Attempts have been made to derive chromatographic fingerprints of the investigated samples following the GC-MS analysis of *Golden Delicious* and *Jonathan* leaf and bark extracts from pesticide non-exposed and exposed matrices.

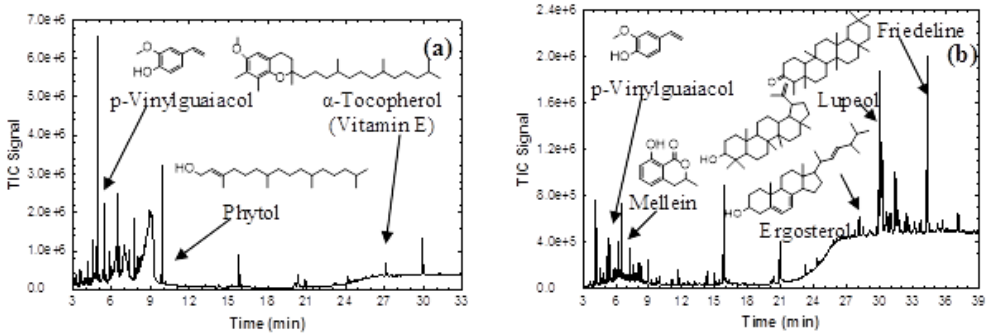

Fig. 1.a,b: Total ion chromatogram (TIC) profiles for pesticides non-exposed *Golden Delicious* matrices: (a) – leaves and (b) – bark methanol extracts.

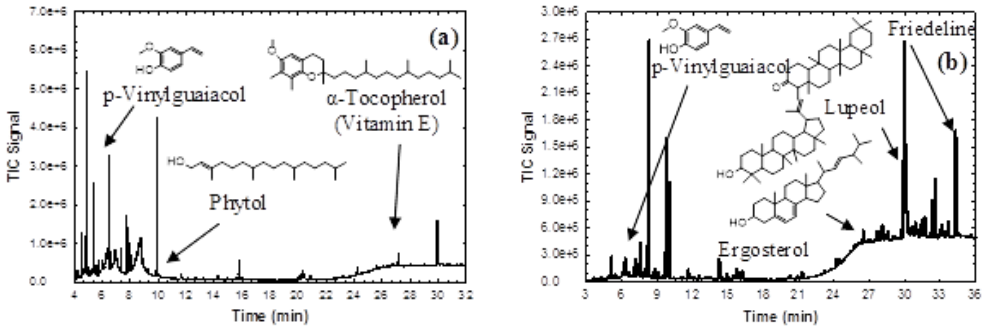

Fig. 2.a,b: Total ion chromatogram (TIC) profiles for pesticides non-exposed *Jonathan* matrices: (a) – leaves and (b) – bark methanol extracts.

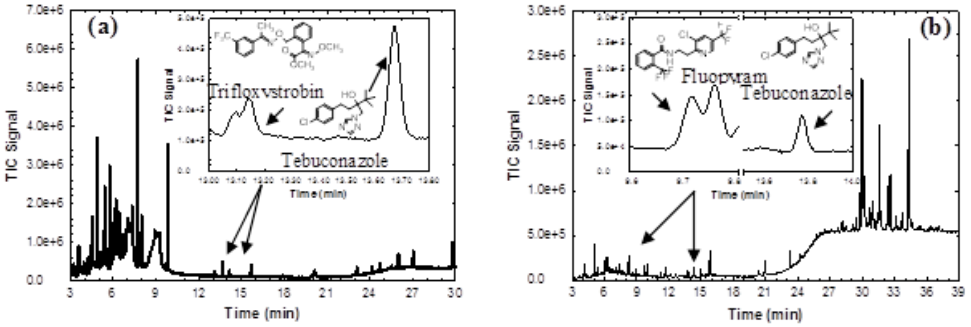

Fig. 3.a,b: Total ion chromatogram frame of methanol extract from pesticides exposed *Golden Delicious* variety: (a) - leaves, (b) - bark. The inset figures highlight in details the chromatographic peaks associated with tebuconazole, trifloxystrobin and fluopyram.

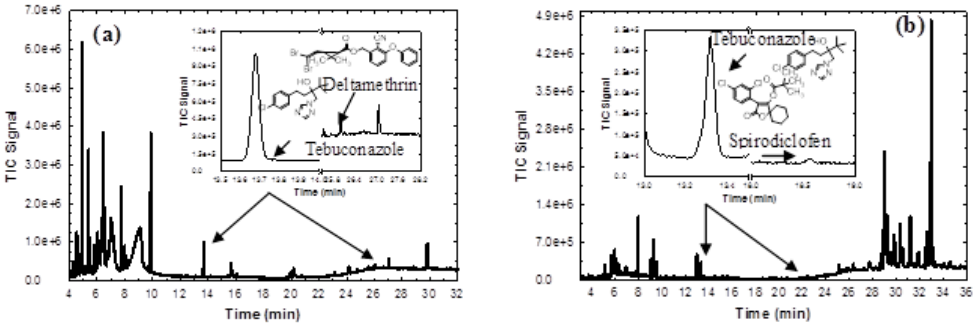

Fig. 4.a,b: Total ion chromatogram frame of methanol extract from pesticides exposed *Jonathan* variety: (a) - leaves, (b) - bark. The inset figures highlight in details the chromatographic peaks associated with tebuconazole, deltamethrin and spirodiclofen.

DISCUSSION

In the present study attempts have been made to derive chromatographic fingerprints of the investigated samples following the GC-MS analysis of *Golden Delicious* and *Jonathan* leaf and bark extracts from pesticide non-exposed and exposed matrices. Figures 1.a,b show some of the main phytochemical constituents (phytol, p-vinyl guaiacol, α-tocopherol/vitamin E) identified in pesticide non-exposed *Golden Delicious* apple leaf (fig.1.a.) and, bark, respectively (fig.1.b.) matrices where compounds such as p-viny guaiacol, lupeol, friedelin, ergosterol, mellein have been identified.

Analysis of the obtained chromatographic profiles highlighted the existence of an important number of bioactive compounds in methanol extracts from both leaves and bark of *Golden Delicious* variety (pesticide non-exposed and exposed matrices) and leaves/bark extracts of *Jonathan* apple variety from pesticide non-exposed and exposed matrices. For sample GC-MS analysis total ion chromatogram (TIC) acquisition mode was preferred to single ion monitoring (SIM) mode and this procedure allowed us to identify a larger array of chemicals. In the investigated pesticide non-exposed matrices several important phytochemical constituents such as methoxyphenol compounds, terpene, tocopherols (α-tocopherol or Vitamin E), phytol, sterols, etc. have been identified.

Chromatographic profiles presented in Figures. 1. a, b and 2. a, b, respectively, clearly highlight features of methanol (MeOH) leave (fig.1.a and fig.2a) and bark extracts (fig. 1.b and fig. 2.b) from pesticide non-exposed *Golden Delicious* and *Jonathan* apple varieties. Regarding the metabolites present in the investigated matrices quite similar information was generated by the investigated samples. However, the abundance of secondary metabolites identified in the analyzed matrices varied from one apple sort to another, i.e. *Golden Delicious* and *Jonathan*. Abundances were determined based on the relationship between the area of each integrated chromatographic pick and the total area of all existent and identified chromatographic peaks (via the NIST database) in a processed signal.

Phytol was identified as one of the most abundant secondary metabolite in both

Golden Delicious and *Jonathan* leaf extracts. Phytol is a secondary metabolite obtained during chlorophylls degradation. It plays an important role in tocopherol synthesis, which is one of the most abundant chloroplast liposoluble antioxidant groups. Analysis of the entire data-base generated by the present study allowed us suggesting the idea about the existence of different metabolic processes in the investigated trees compartments, in full agreement with information from the literature. Phytol is a widespread diterpenoid compound, and recent studies have shown that phytol can act as an excellent immunostimulant with antioxidant, anti-inflammatory and anti-allergic properties (13). Moreover, phytol exhibits also antimicrobial activity against *Mycobacterium tuberculosis* (14) and *Staphylococcus aureus* (15).

α-Tocopherol known also as vitamin E is another important secondary metabolite identified in leaves but not in bark extracts. Vitamin E is the name of all known varieties, referring to a group of compounds exhibiting biological activity, and an example of such a compound is α-tocopherol. It is an active chemical ingredient with one of the highest biological activity in most biological systems. However, the results of recent research studies indicate that there are other vitamin E compounds that can be even more efficient in specific biological mechanisms. Due to its solubility in fat, α-tocopherol has a unique function of protecting cell membranes made of fatty acids against damage by the action of Reactive Oxygen Species (ROS) and is also involved in the photosynthesis process (16).

Another important metabolite identified in leaf and bark extracts of pesticides non-exposed and exposed *Golden Delicious* and *Jonathan* matrices is p-vinyl guaiacol (PVG). It is an important metabolite generated during ferulic acid degradation and is an abundant phytochemical compound found in plant cell wall compartments. The presence of p-vinylguaiacol in the investigated matrices could suggest its potential importance as a phenolic compound existent in various plants' compartments usually known for their high content of antioxidant potential components (17).

In pesticides non-exposed leaves and bark methanol extracts from *Golden Delicious* and *Jonathan* apple varieties, compounds of pharmacological interest, i.e. lupeol, friedelin, α-tocopherol/vitamin E, methoxyphenols, mellein, have also been identified. Introspection of the recorded chromatograms revealed that good separation resolution was achieved for most identified compounds. Although now the information is only of a qualitative nature, the results can then be exploited in establishing strategies for appropriate scientific approaches to elucidate aspects related to the role and implications induced by the presence of pharmacologically relevant metabolites in the investigated matrices.

Lupeol is another secondary metabolite identified in *Golden Delicious* (fig. 1.b) and *Jonathan* (fig. 2.b) bark. It is a triterpene known mainly as fagarsterol and is a compound for which there are suggestions that it would have beneficial effects as a therapeutic and preventive agent for various diseases. Over the past 15 years, much improvement has been made regarding development of this very important molecule for clinical use in the treatment of various disorders. Various studies, focusing on investigating lupeol's action mechanism or its anti-inflammatory potential, have also proven that effective therapeutic doses do not present toxicity to normal cells and

tissues (18). In a research study on lupeol's ester effects it has been shown that this compound posess higher anti-inflammatory properties than indomethacin, with stronger effects in reducing arthritis foot inflammation in rats (19).

In *Golden Delicious* (fig. 1.b) and *Jonathan* (fig. 2.b) bark matrices friedelin was another important secondary metabolite identified. The results of various research studies reported in the literature have indicated that friedelin is very efficient in the treatment of inflammatory diseases, and that it can act as a potential drug with analgesic and antipyretic effect. Synthesis process inhibition and inhibition in the release of inflammatory mediators are considered as important action mechanism for this compound. Due to friedelin's remarkable biological activity presently is strongly believed that it would be imperiously necessary to carry out further research to develop a drug containing this active ingredient (20). In another research study it has been shown that friedelin has also antidiarrheal activity due to its anti-secretory and intestinal anti-motility properties (21).

In the methanol extract of *Golden Delicious* bark (Fig. 1.b) mellein appears as another identified compound. It is an active compound assigned as hepatitis C inhibitor. Mellein compounds are well-known dihydroisocoumarins that are widely distributed in fungi. According to the details in Pontius et al., 2008 (22), mellein was firstly described as a metabolite from *Aspergillus melleus* in 1933. The *Aspergillus ochraceus* extract was found to inhibit the final polyprotein processing step in the hepatitis C virus replication time interval and this fractional bioassay process resulted in the isolation of mellein as an active component of the extract (23).

Vitamin E was identified in *Golden Delicious* (fig. 1.a) and *Jonathan* (fig. 2.a) leaves extracts. Vitamin E antioxidant properties are well known, but in recent years the research interests switch to the potential of this vitamin to be used in pediatrics. It seems that vitamin E supplementation during pregnancy is required especially for α-tocopherol concentration in the colostrum (24) while after a high-risk pregnancy it would be necessary (25).

Analysis of the chromatograms presented in Figure 3.a,b and Figure 4.a,b, respectively, presenting TIC signals of *Golden Delicious* and *Jonathan* methanol (MeOH) leave (fig. 3.a and fig. 4.a) and bark (fig. 3.b and fig. 4.b) extracts clearly revealed the presence of the pesticides of interest in the investigated matrices. Use of an optimized analysis method for the investigation of the matrices of interest by the GC-MS technique has resulted in the identification of tebuconazole at a retention time of 13.75 minutes. In the chromatograms associated with pesticide exposed matrices it was also possible to detect other pesticides present in the in-use clearly stated combinational pesticides formulations. In any case, while for the chromatographic peak associated with tebuconazole the analytical aspects were very clear, it seems that for other compounds the method should be optimized.

Analysis of the chromatographic details specific for *Golden Delicious* bark extracts in pesticide non-exposed and exposed matrices (fig. 1.b and fig. 3.b) allowed us to identify the fact that peak intensity associated with mellein (fungus) gradually diminished after pesticides treatments spread. It is believed that such behavior clearly underlines the potential aggressive effect of treatment components on various promising phytochemical constituent existent in

plant compartments.

CONCLUSIONS

In our study methanol extracts from *Golden Delicious* and *Jonathan* leave, and bark matrices collected from an orchard in Iasi, northeastern Romania were obtained, and a systematic investigation of the existing secondary metabolites was conducted for the first time. Compounds of pharmacological interest, i.e. lupeol, friedelin, α-tocopherol/vitamin E, mellein, have been identified with output creating premises for subsequent scientific approaches in the topic of interest. In the pesticide exposed matrices subjected to GC-MS analyses, there was clear evidence of the presence of tebuconazole and other pesticides in the in-use clearly stated combinational pesticides formulations, containing trifloxistrobin, deltamethrin, fluopiram and spirodiclofen. By monitoring the behavior of mellein metabolite (fungus), mainly existent in the bark of *Golden Delicious* variety, it was possible to highlight the potential aggressive action of the in-use clearly stated combinational pesticides formulations on promising phytochemical constituent existent in various plant compartments.

DESCRIPTIVE STUDY ON ACUTE GASTROENTERITIS IN 3883 PATIENTS ADMITTED IN "SF. MARIA" CHILDREN HOSPITAL FROM IASI, ROMANIA, BETWEEN 2008 AND 2013 (Abstract): The **aim** of study was to assess some population characteristics in children of acute gastroenteritis (AGE) admitted in a regional pediatric hospital. **Material and methods**: For the present transversal descriptive study we considered a group of subjects hospitalized for AGE in 2008-2013 (2013 – only 6 months) in "Sf. Maria" Emergency Hospital for Children Iasi, Romania. Consultations in the Emergency Unit of this hospital did not take into consideration. **Results**: Number of AGE cases admitted to “St. Maria” Emergency Hospital for Children Iasi between 2008 and 2013 has seen a steady decline. Male subjects are better represented (54.1%); largest age group 1-4 years, with 1,827 cases, immediately followed by group 0-1 year (1789 cases); together, the two age groups account for 93.1% of admissions for AGE. Distribution of cases by seasons showed balanced values, with higher percentages in summer (29.7%) and spring (25.5%). The number of cases is relatively constant and lower in winter, affecting predominantly younger groups (0-5 years) compared to the summer when cases aged 5 to 14 years were admitted more frequent. Most cases presented at admission vomiting (41.2%) and fever (40.7%); the presence of bacterial flora was identified in 82.2% of stool specimens, and blood in 13.4% of cases. **Conclusions**: A higher number of education measures should be implemented in urban and rural areas in order to decrease the contamination with pathogenic agents involved in infectious acute gastroenteritis in children. **Keywords:** ACUTE GASTROENTERITIS, PEDIATRICS, DIARRHEA, EPIDEMIOLOGY

Acute diarrheal disease (acute gastroenteritis - AGE) has a high prevalence worldwide and the information came as a result of epidemiological surveillance are of great practical importance. In order to intervene appropriately in situations affecting public health, surveillance systems need to provide correct and complete data about AGE often under diagnosed and underreported, particularly parasitic and viral etiologies (1, 2).

“Sf. Maria” Emergency Hospital for Children Iasi is the largest children's hospital in Moldova, assisting the Iasi County

and the other seven districts of Moldova, Romania. The number of children hospitalized annually range from 28,680 in 2012 to almost 34,000 (2009) of which 5.2% are cases with a diagnosis of AGE (primary or secondary).

MATERIAL AND METHODS

For the present transversal descriptive study we considered a group of subjects hospitalized for AGE in 2008-2013 (2013 – only 6 months) in "Sf. Maria" Emergency Hospital for Children Iasi, Romania. Consultations in the Emergency Unit of this hospital did not take into consideration.

The criterion for inclusion in the study was the main diagnosis of AGE at discharge, so that only 3,883 cases (2.2% of all admissions) were selected from all cases of AGE recorded between 2008-2013 (8,986 cases - 5.2% of all admissions).

The following variables on the characteristics were studied: distribution by years, gender, age group, area of residence, number of hospitalization days, by seasons, and some clinical aspects.

Database was performed in MS-Excel 2010 software. Statistical analysis was performed with *SPSS 20.00*. For comparison, we used the χ^2 test (chi-square). The value of p (significance level) which reflects the probability that the difference between the analyzed variables are random, was considered greater than 0.05.

RESULTS

Of the total admissions between 2008 and 2013 (174,490 cases), 8986 cases (5.2%) were diagnosed with AGE, and 3,883 of those (2.2% of all hospitalized patients) were selected for our study, suffering from AGE as main diagnosis.

Number of cases with AGE, admitted to "Sf. Maria" Emergency Hospital for Children Iasi has seen a steady decline, higher in 2010, 2011, 2012 (from 1057 and 1016 cases in 2008 and 2009 to 672 in 2010, 571 in 2011, and 448 in 2012) (fig. 1).

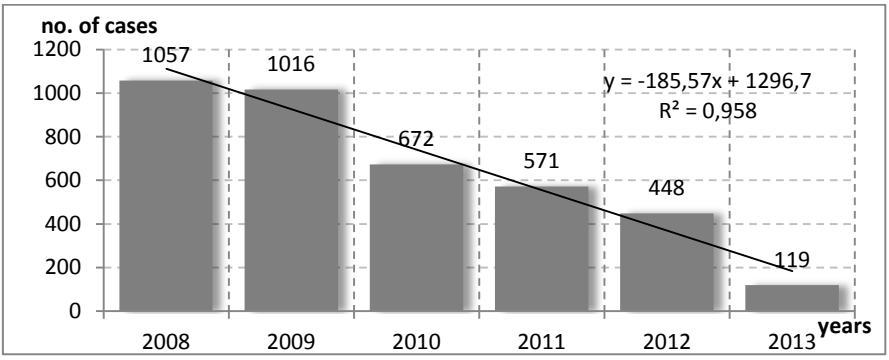

Fig. 1 Distribution by years

Distribution of cases by sex has a higher value in males (54.1%), and the best represented age group was 1-4 years old, with 1827 cases, immediately followed by group 0-1 year (1789 cases); together, the two age groups accounted for 93.1% of admissions for AGE. The mean age of the entire group of 3383 children was 1.29 years. In males and children from rural areas, the mean age is below that of the entire group of study (1.26 or 0.99) (tab. I).

TABLE I
Mean age of cases by sex and residence area

Age	Total of group	Comparative values – by sex		Comparative values – by residence area	
		Female	Male	Rural	Urban
Mean	**1.29**	**1.32**	**1.26**	**0.99**	**1.50**
Standard error of the mean	0.036	0.055	0.047	0.054	0.047
Standard deviation	2.226	2.308	2.154	2.148	2.256
Minimum	0	0	0	0	0
Maximum	14	14	14	14	14

In the 0-1 age group, most cases were recorded in 2008 then the frequency of admissions decreased, reaching 56 cases in 2013. From group 1-4 years, 5-9 and 10-14, most children were admitted in 2009 (517, 53 and 25 cases, respectively) and the fewest in 2013 (49, 7, and 7 cases, respectively) (fig. 2).

Distribution by age and sex showed that only in the 10-14 age group, the girls were sick more often than boys (55.7% *vs* 44.3%; in the other age group, AGE affected predominantly males, but statistically not significant (p=0.071) (fig. 3).

Most children with AGE were from urban areas, regardless of age, this distribution was statistically significant (p <0.0001) (fig. 4).

Distribution of AGE cases by seasons was relatively uniform, only in summer, there were more cases (29.7% of total), with a cumulative maximum in July (403 cases) and a minimum of 250 cases in November, with a moderate statistical significance (p=0.038) (tab. II).

N of Valid Cases	3883		

a. Test distribution is normal/*SS - statistically significant

In all age groups, the fewer cases were recorded in the winter, and most of the summer, except for children 10-15 years old, who presented more AGE admissions in fall season (31.6%) than in summer (24.1%), that situation might be due to start school in September (fig. 5).

The reported frequency of clinical signs at admission (other than diarrhea which was the criterion for inclusion) was: vomiting (41.2%), fever (40.7%), loss of appetite (17.1%), and abdominal pain (9.9%). Results of cytograms from stool specimens on admission showed bacterial flora present in 82.2% of cases, the mucus in 48.8%, PMN leukocytes in 27.7%, and enterocytes in 14.6%. 13.4% of samples were positive for blood, and this was highly significant statistic in the age group 0-1 years and 1-4 years (tab. III).

Number of hospitalization days had a mean of 5.04 for children of 0-1 age group, with a maximum of 30 and a minumum of 1 day. The mean was 3.92 days in cases from 1-4 age group, 3.17 in cases of 5-9 years old and 3.41 in 10-14 age group, being statistically significant ($p<0.0001$) at Kruskal-Wallis test and Kolmogorov-Smirnov test (tab. IV, fig. 6).

DISCUSSION

Acute gastroenteritis is a common cause of significant morbidity and mortality worldwide, despite the successful introduction of oral rehydration solutions in the 1980s (3, 4). In financial developed regions, AGE is rarely fatal, but in others, more than 1.5 million children die annually. In Europe, it was estimated that 16% of children presentation in emergency rooms are for AGE with any etiology, so that AGE becomes the second most common cause of hospital admission after acute respiratory tract infections (3, 5). AGE accounted for 7-10% of all admissions in children under 5 years old in the developed countries (3).

Wiegering V. et al, in a study conducted in a University Hospital (Würzburg) reported a different number of hospitalization days according to etiologic spectrum, from 4.9 +/- 0.1 days for viral etiology at 5.7 +/- 0.4, respectively bacterial etiology *Salmonella* infection (6). Clinical signs with statistical significance in viral and bacterial AGE were bloody diarrhea and fever in a study conducted over a period of 14 years in Spain, by Alcalde et al. (7).

CONCLUSIONS

Number of AGE cases admitted to "Sf. Maria" Emergency Hospital for Children Iasi between 2008 and 2013 has seen a steady decline. Male subjects are better represented (54.1%); largest age group 1-4 years old, with 1,827 cases, immediately followed by group 0-1 year (1,789 cases); together, the two age groups account for 93.1% of admissions for AGE. In fact, studies of AGE in children could be performed just by the 0-5 age group, but in order to assess the number of hospitalizations and their frequency should be considered the whole group of 0-14. The mean age of the entire group of 3,383 children is 1.29 years, which reflects a concentration of cases in younger age groups.

Distribution of cases by seasons showed balanced values, with higher percentages in summer (29.7%) and spring (25.5%). The number of cases is relatively constant and lower in winter, affecting predominantly younger groups (0-5 years) compared to the summer when cases aged 5 to 14 years were admitted more frequent.

The study was considered only cases with acute diarrhea on admission. Most cases presented at admission vomiting (41.2%) and fever (40.7%).

The presence of bacterial flora was identified in 82.2% of stool specimens, and blood in 13.4% of cases.

Bacterial etiology can be suspected in most cases.

IN VITRO EVALUATION OF ANTIBACTERIAL EFFICACY OF PINEAPPLE EXTRACT (BROMELAIN) ON PERIODONTAL PATHOGENS

Periodontitis represents an inflammatory disease resulting in the destruction of periodontal tissues. Various treatment modalities (mechanical and surgical therapy) have been tried. Antimicrobial agents have been used as a monotherapy and as an adjunct with mechanical debridement. As antibacterial agents have been used different plant extracts. Pineapple extract (Bromelian) is one such agent. The aim of the study was to assess the antibacterial efficacy of Bromelain on aerobic and anaerobic periodontal microorganisms. Minimum inhibitory concentration (MIC) of Bromelain was tested on isolated strains of *Streptococcus mutans*, *Enterococcus fecalis, Aggregatibacter actinomycetemcomitans* (Aa), and *Porphyromonas gingivalis* (Pg) using serial dilution broth method. The results of the study showed that *S. mutans* showed sensitivity at the lowest concentration of 2 mg/ml as compared to *E fecalis* (31.25 mg/ml) while *P gingivalis* showed sensitivity at the lowest concentration of 4.15 mg/ml as compared to *Aggregatibacter actinomycetemcomitans* (16.6 mg/ml). In conclusion Bromelain exerts an antibacterial effect against potent periodontal pathogens; hence, it may be used as an antibacterial agent. To validate this result further trial has to be conducted. (Praveen NC, Rajesh A, Madan M, Chaurasia VR, Hiremath NV, Sharma AM. In vitro Evaluation of Antibacterial Efficacy of Pineapple Extract (Bromelain) on Periodontal Pathogens. *J Int Oral Health*, 2014; 6 (5): 96-98).

Department of Vascular Surgery

CLINICAL AND EPIDEMIOLOGICAL ASSESSMENT CONCERNING HYBRID REVASCULARIZATION TECHNIQUES IN THE TREATMENT OF MULTILEVEL PERIPHERAL ARTERIAL OCCLUSIVE DISEASE (Abstract): **Aim** of the study was to report a novel hybrid technique for multilevel arterial lesions of the lower extremities and to evaluate the clinical outcomes. In patients with multilevel arterial disease, the combined (hybrid) treatment, consisting of endovascular intervention and classical surgical intervention on the same vascular axis seems to be the most indicated treatment in order to obtain an adequate inflow and outflow. **Material and methods**: we have performed a non-randomized study during a 44-month period (January 2010 – September 2013) in a number of 94 patients treated by hybrid revascularization techniques. All the patients included in the study have been post-surgically surveyed at well established intervals (1, 3, 6, 9, 12, 24 and 36 months) by: clinical examination, laboratory tests, Duplex ultrasound, and, as needed, CT or MR Angiography. **Results**: the 6 months primary patency in each studied group (corresponding to the years of 2010, 2011 and 2012) was 58.69%, 68.42%, and 62.06%, respectively; the 12 months primary patency was 45.65%, 57.89%, and 34.48%, respectively. Clinical improvement has been noticed in 83 patients (88.29%). There have been registered 19 amputations (20.21% of the cases): 11 majors (thigh and below the knee), representing 11.7% of the total number of cases and 8 minors (toe or transmetatarsal), representing 8.51% of the total number of cases. The amputation-free survival period ranged between 7 days and 24 months, with an average of 7.66 months. **Conclusions**: the hybrid techniques are a feasible option for the multilevel arterial disease, with favorable patency and limb salvage rates. **Keywords**: MULTILEVEL ARTERIAL DISEASE, HIBRID REVASCULARIZATION

Multilevel involvement is typically observed in peripheral arterial occlusive disease (PAOD). A staged approach to multilevel occlusive disease was the standard for numerous years, consisting of balloon angioplasty of the iliac artery followed by interval infrainguinal surgery (1, 2). This approach was a rational strategy at a time when open and endovascular surgical techniques were only performed in separate settings.

Multilevel revascularization, using a combination of endovascular and open techniques, was first reported in the early

1990s (3). Hybrid surgery is ideal for multilevel lesions, as it allows the application of minimally invasive treatment on complex anatomy in high-risk patients. Usually, the procedures are performed simultaneously, although individual patient anatomy plays a part in the decision of whether to perform the two procedures simultaneously or not. The aim of the treatment is to obtain an improvement of both the inflow and the outflow (4, 5).

The rate of hybrid interventions has progressively increased during the last decade and it is estimated to be around 5-20% of all vascular reconstructions (6).

In the hybrid technique, the endovascular stage can be an inflow procedure, an outflow procedure, a combination of the two, or a bypass revision.

The open techniques consisted of an autologous or synthetic bypass graft and/or endarterectomy.

MATERIAL AND METHODS

We have performed a non-randomized study in two centers. The data was gathered retrospectively for a 20-month period (January 2010 – September 2011), and prospectively for a 24-month period (September 2011 – September 2013) for a number of 94 patients treated by hybrid revascularization techniques at the Cardiovascular and Thoracic Surgery Clinic, "Imelda" Hospital, Bonheiden, Belgium.

The including criteria for the patients were: aged 18 and over, multilevel peripheral arterial disease in any of the Leriche-Fontaine stages, with uni- or bilateral pathology, and had an indication of hybrid revascularization by both endovascular therapy (either balloon angioplasty, stenting or endoprosthesis insertion), and an open technique (bypass or endarterectomy, with or without angioplasty). The study included 94 patients (female 35.1%, male 64.9%, mean age 70,68 years).

The patients were divided into two groups: 1 – included patients who had the hybrid techniques done in one procedure; 2 – included patients treated in two succesive procedures.

The second group was divided into two sub-groups of patients: one for which the open revascularization technique was done first, followed by an endovascular procedure; and the second, for which the initial procedure was the endovascular one, followed by the open technique.

Peripheral arterial disease was localized at a minimum of two levels on the same vascular axis: aortic, iliac, inguinal (involving the common, deep femoral artery and the origin of the superficial femoral artery), or infrainguinal (supra- or infragenicular).

All patients were pre-operatively evaluated by physical examination, blood tests, Duplex scan, CT or MR Angiography. Also, the risk factors and associated co morbidities were noted.

Postoperative surveillance at well established time intervals (1, 3, 6, 9, 12, 24 and 36 months), consisted of: blood tests and Duplex scans, clinical examination (improvement of the claudication distance, amelioration of rest pain, healing of trophic lesions).

We evaluated the primary patency, assisted primary patency and secondary patency of all procedures, initial technical success, complication rate, morbidity and mortality associated with each technique, amputation-free survival rate, symptomatic improvement, and the risk factors that influenced the postoperative outcome and recovery period.

The *statistic analysis* and *epidemiologi-*

cal data were performed in *SPSS 15.0* (SPSS Inc., Chicago, IL, USA). A p value of less than 0.005 was considered statistically significant.

During the study, the primary and secondary patency were analyzed using the Kaplan-Meier estimator.

RESULTS

Thirty-three patients (35.10%) were revascularized by simultaneous hybrid procedures and 61 patients (64.89%) by succesive hybrid procedures: the open technique of 42 patients (44.68%) was followed by an endovascular procedure and in 19 patients (20.21%) the endovascular technique was followed by an open procedure (fig. 1).

The majority of patients treated by simultaneous hybrid procedures were classified as stage II Leriche-Fontaine (fig. 2).

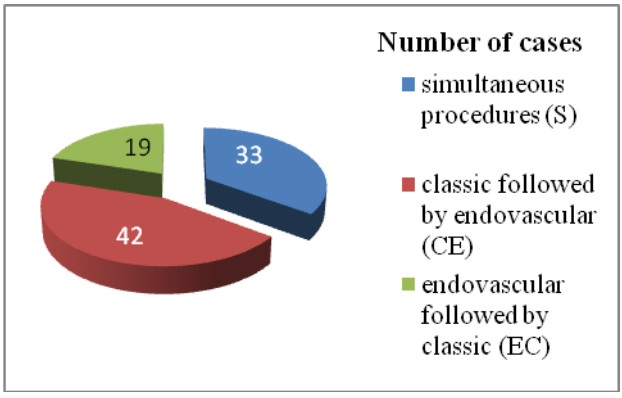

Fig. 1. The distribution of cases according to the revascularization procedure sequence

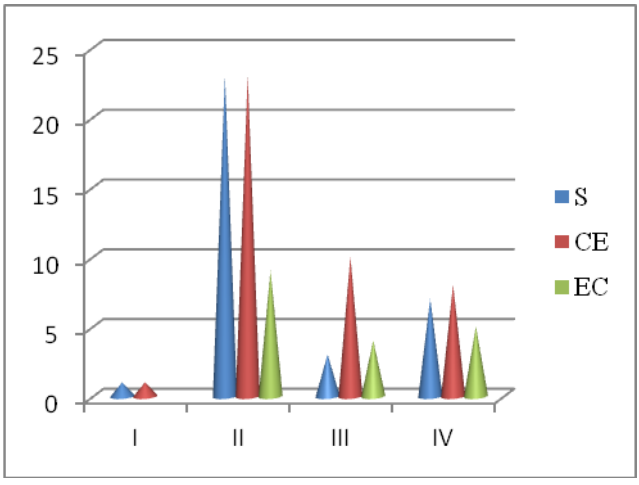

Fig. 2. The distribution of hybrid procedures according to the disease stage.

For the studied period of time, there were 49 bypass procedures performed, 37 common femoral artery endarterectomies and angioplasties, 23 desobstructions using the Fogarty catheter, 97 thrombolysis procedures, 164 endovascular angioplasties

and 100 endovascular angioplasties followed by stenting.

Elective procedures were performed for 61.7% of the patients and emergency procedures for the rest of 38.3% of the patients, with acute or subacute ischemia. Emergency procedures consisted of thrombolysis, bypass, or native artery thrombectomies, with or without a bypass or supra/subjacent percutaneous angioplasties (PTA) on the same arterial axis.

The initial technical success for all procedures was 100%.

We had 19 early artery or bypass occlusions (less than 30 days) and one case with a postoperative local haematoma which required a reintervention for haemostasis and evacuation.

We had one severe graft infection (for which a myoplasty was performed, with favorable postoperative recovery) and 78 late occlusions (after more than 30 days), which entailed follow-up procedures for reestablishing the patency.

We had 7 intra-stent stenoses at the level of the superficial femoral artery, which were solved by angioplasty and restenting or femoro-popliteal bypass.

There were19 (20.21%) amputations recorded :11 majors (thigh or below-knee), representing a rate of 11.7% of the total number of cases and 8 minors (toe or transmetatarsal), representing a rate of 8.51% of all cases. The major amputations were 10 unilateral and one bilateral (successive). Limb salvage rate for the patients in stage III and IV Leriche-Fontaine was 73.17%. Clinical improvements was noticed in 83 (88.29%) patients. After six months primary patency in each studied group (corresponding to the years of 2010, 2011, and 2012) was 58.69%, 68.42%, and 62.06% respectively, comparable with those published in the literature. After twelve months primary patency was 45.65% in the 2010 studied group, 57.89% in the 2011 group of patients, and 34.48% for the 2012 group (fig. 3, 4, 5).

We did not find statistically significant differences between the averages of the primary patency of various disease stages. The mortality rate for the entire period studied was 0% .

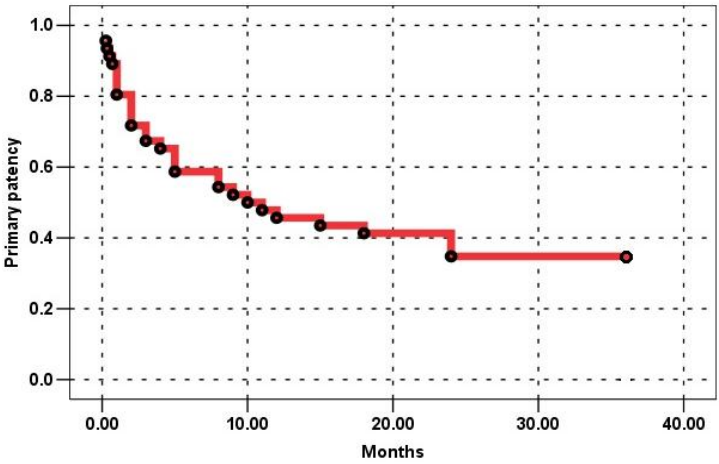

Fig. 3. The Kaplan-Meyer diagram of primary patency for the 2010 patient group

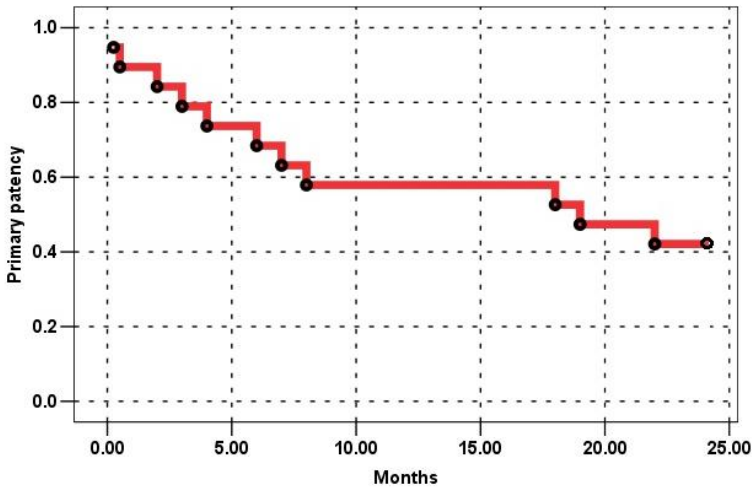

Fig. 4. The Kaplan-Meyer diagram of primary patency for the 2011 patient group

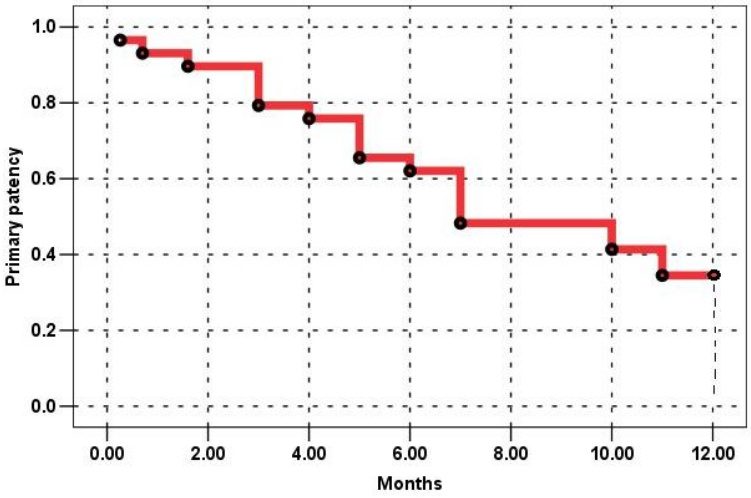

Fig. 5. The Kaplan-Meyer diagram of primary patency for the 2012 patient group

In regards to the influence of the hybrid procedure type on the primary patency (PP), we found that in the case of succesive endovascular and open procedures, the average PP is significantly higher compared to the PP of open technique followed by an endovascular procedure (Fig. 6).

The statistic analysis identified the only risk factors which significantly influenced the primary patency in the studied group: *obesity* and *renal insufficiency*.

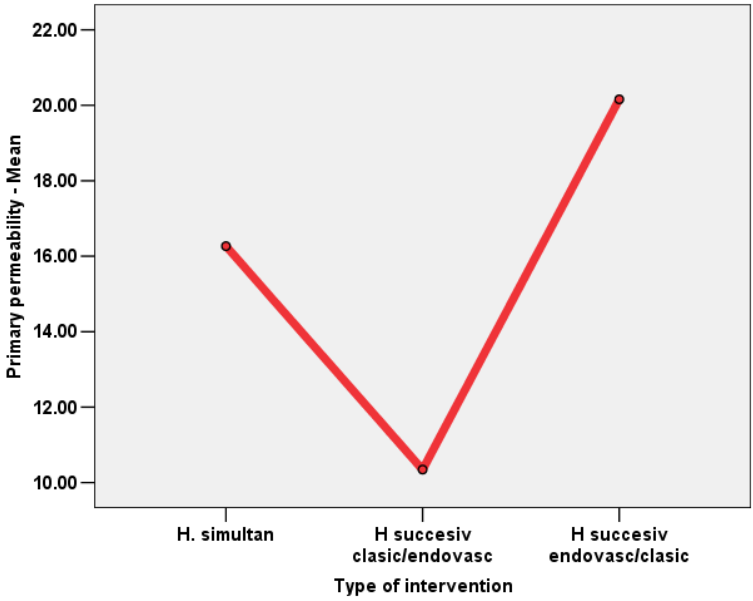

Fig. 6. The influence of the type of hybrid procedure on the primary patency

DISCUSSION

Implementing hybrid techniques in the vascular surgery practice and the possibility of performing them in hybrid operating rooms offer therapeutic options that come to meet the needs of the patients with multilevel lesions and high surgical risk.

For the cases treated in a simultaneous hybrid manner, the main role was played by the common femoral artery (CFA), and its suitability for supra- or subjacent endovascular angioplasty. Endarterectomy, with or without patch angioplasty has been performed on this artery in 28 cases.

The most common endovascular procedure user was baloon angioplasty followed by stenting. Combined open and endovascular revascularization may be performed with either a staged or simultaneous approach. Endovascular surgery has been enthusiastically embraced by a large number of vascular surgeons, leading to increased experience with these types of procedures. In numerous hospitals, hybrid operating rooms have been constructed, making it possible to use both open and endovascular techniques. It is both easy and comfortable to perform simultaneous hybrid surgery in this environment. The hybrid approach has several advantages (7). Firstly, there is no delay in providing complete revascularization to the ischemic limb. Secondly, the length of hospital stay is reduced and finally, puncture-site complications are eliminated since the target artery is accessed through the surgical field and the access site becomes the location of proximal anastomosis.

Cotroneo *et al* (8) reported on 2-year results of hybrid revascularization. The technical success rate was 100% whilst the primary patency rate was 86.2% at 6 months and 79.1% at 24 months. Hybrid surgery has a theoretical advantage com-

pared with open or endovascular revascularization performed separately, in terms of patency rate. With hybrid surgery, inflow or outflow arteries may be revascularized, which may affect the patency rate.

Antoniou *et al* (9) also reported on 3-year results of hybrid revascularization. The technical success rate was 100%. Primary patency rate was 71%.

The annual number of hybrid procedures is increasing. Aho and Venermo (10) reported that this number ranges between 4, in 2004, and 73, in 2011. Out of this total number of hybrid procedures, the proportion performed by vascular surgeons increased from 0% in 2004 to 86.3% in 2011. Relatively young vascular surgeons have adopted endovascular surgery and became familiar with it. According to a survey conducted by the Society for Vascular Surgery (11), younger vascular surgeons (aged <50 years) frequently reported that >50% of their workload is endovascular, compared with older vascular surgeons (aged ≥50 years) ($P<0.001$). The endovascular skills of vascular surgeons have improved through education and simulator-based endovascular skills training (12, 13, 14, 15).

CONCLUSIONS

Hybrid interventions have become a well-accepted strategy for revascularization in patients with critical limb ischemia due to multilevel arterial occlusive disease. Technical success and short- and long-term limb salvage outcomes of hybrid interventions have been shown to be at least comparable to the conventional endovascular and surgical revascularization procedures. Hybrid revascularization offers the efficiency and convenience of a single-stage therapy without added risks for those with lower extremity ischemia.

In our study hybrid procedures are a feasible option for multilevel peripheral arterial occlusive disease, with favorable patency and limb salvage rates. The observations of the current study indicate that femoral endarterectomy plays an important role in hybrid surgery.

ROLE OF OSTEOPROTEGERIN CGA HAPLOTYPE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Osteoprotegerin (OPG) has been associated with increased risk of atherosclerotic disease in the general population and have been described several polymorphisms in the OPG gene with functional effects on cardiovascular disease in non-rheumatic individuals. A group of researchers from Spain aimed to analyze the effect of three of functional OPG polymorphisms on the risk of cardiovascular disease in a large and well-characterized cohort of patients with rheumatoid arthritis. Three OPG gene variants (rs3134063, rs2073618 and rs3134069) were genotyped by TaqMan assays in 2027 patients with rheumatoid arthritis. Anti-cyclic citrullinated peptide (anti-CCP) antibody testing was positive in 997 of 1714 tested. Also, 18.3% of the whole series had experienced cardiovascular events, including 5.4% with cerebrovascular accidents. The relationship between OPG variants and cardiovascular events was assessed using Cox regression.No association between OPG gene variants and cardiovascular disease was observed in the whole group of rheumatoid arthritis patients or in anti-CCP positive patients. Nevertheless, a protective effect of CGA haplotype on the risk of cardiovascular disease in general, and specifically in the risk of cerebrovascular complications after adjusting for sex, age at disease diagnosis and traditional cardiovascular risk factors was disclosed in anti-CCP negative patients. They concluded that their results indicated a protective effect of the OPG CGA haplotype on cardiovascular risk, mainly due to a protective effect against cerebrovascular events in anti-CCP negative rheumatoid arthritis patients. (Genre F, López-Mejías R, García-Bermúdez M et al. Osteoprotegerin CGA Haplotype Protection against Cerebrovascular Complications in Anti-CCP Negative Patients with Rheumatoid Arthritis. *PLoS One.* 2014 Sep 3; PMID:25184828).

EPIDEMIOLOGICAL AND LABORATORY FEATURES OF CHRONIC HEPATITIS B CASES IN THE INTERVAL 2010-2013 (Abstract): HBV virus infection is an important public health problem because of its huge transmission potential, and severe evolution to cirrhosis or liver cancer. **Aim**: Analysis of the epidemiological and laboratory features of chronic hepatitis B virus infection. **Material and methods**: The patients with chronic hepatitis B admitted to the "Sf. Parascheva" University Hospital for Infectious Diseases in the interval: January 1st, 2010 – December 31st were analyzed. **Results**: Patients age was 18 to 66 years with a prevalence of middle-aged males. Most patients came from urban areas. Alanine aminotransferase (ALAT) levels were elevated, without significant differences between HBeAg-positive and HBeAg-negative patients, the elevated ALAT levels being associated with the increased prevalence of fibrosis. HBeAg-positive patients had viral loads above the threshold of 2,000/l in 34 cases (89.5%), and below 2,000 IU/l in only 10.5% of cases, and the majority (88%) of HBeAg-negative patients presented high viral load levels. The prevalence of stage F2-F4 liver fibrosis was 63.4% in the HBeAg-negative patients with viremia > 25,000 IU/l compared to 55.2% in the HBeAg-positive patients. The correlation between the level of viral load and fibrosis shows that there are significant differences between viremia and the status of HBeAg-positive or negative patients. Increased viral load was correlated with increasing prevalence of fibrosis, significant in HBeAg-negative patients, and the increasing fibrosis prevalence was correlated with low viral load. **Conclusions:** The correlation between viral load and fibrosis shows that there are significant differences between viral load and the status of HBAg-positive or negative patients. **Keywords**: VIRAL LOAD, FIBROSIS, SEROLOGICAL MARKERS

Infection with hepatitis B virus (HBV) is a major public health problem due to the great number of people affected nationally and worldwide. Although in most adults acute symptomatic hepatitis B virus infection is clinically curable, the factors contributing to infection persistence and chronic evolution are not fully known yet. The current importance of acute hepatitis caused by HBV is due to its worldwide spread, high potential of chronicization, especially in newborns, and slow, possibly severe progression to cirrhosis or hepatocellular carcinoma; despite vaccination, the

disease is the 10th leading cause of death worldwide. This paper presents the results of an analysis of epidemiological and laboratory features of chronic hepatitis B cases admitted to the Iasi "Sf. Parascheva" University Hospital for Infectious Diseases during a four year interval, 2010-2013.

MATERIAL AND METHODS

The medical records of 401 adult patients (over 18 years) diagnosed with chronic hepatitis B admitted to the Iasi "Sf. Parascheva" University Hospital for Infectious Diseases between January 1st, 2010 and December 31st, 2013 were reviewed in view of describing the demographic, epidemiologic and virologic characteristics. The following laboratory variables (blood counts, liver samples, HBV-DNA and viral load determinations) were analyzed and correlations were made between the serological and biochemical markers according to area of residence (urban/rural), age, and sex of patients. Serological tests were done to determine HBsAg, HBeAg, total anti-HBe, anti-HBe, and antibodies to HDV in view of detecting HBV-HDV co-infection, and quantitative virologic tests were used as a guide mark for assessing progression severity in relation with the fibrosis grade. The patients in which HBsAg was present for over 6 months, regardless of hepatocytolysis level and viral load were considered to have chronic infection. Statistical analysis data was performed with the help of *SPSS* software, using confidence intervals, statistical significance tests, variations, dispersion, and correlation.

Descriptive analysis of the cases showed that the annual number of chronic hepatitis B cases was 150 (37.40%) in 2010, 88 (21.94%) in 2011, and 93 (23.19%) in 2013, with a male predominance (64.83%). The mean age of the study group was 41.61 years (range 18-66 years), most patients belonging to the 51-60 (26.93%) and 31-40 (25.68%) age groups (fig. 1).

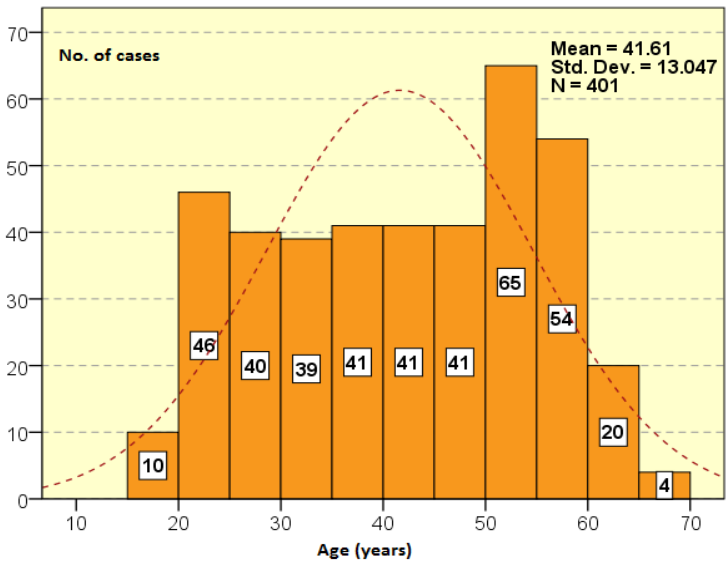

Fig. 1. Age distribution of study cases

The fewest cases were recorded among elderly and young adults, indicating the prevalence of middle-aged patients. Distribution by area of residence showed the prevalence of urban areas (284 cases - 70.8%); sex ratio was in favor of males, with 272 cases (64.83%). Serum transaminase levels ranged from normal to 520 IU, 35% of patients having ALAT levels within normal ranges. Transaminase levels were high, without significant differences between HBeAg-positive and HBeAg-negative patients (average 118 IU/l), slightly higher in HBeAg-positive patients. In HBeAg-positive cases, transaminase levels ranged from 75 to 290 IU/l, average 118.5 IU/l, with a standard deviation of 324.36, while in HBeAg-negative cases transaminase levels were lower (< 150 IU/l), standard deviation 184.23, but without significant statistical differences. Increased ALAT level was associated with increasing prevalence of fibrosis, in both HBeAg-positive and HBeAg-negative patients. Serological marker analysis showed that 38 patients were HBeAg-positive (9.5%) and 363 patients (90.5%) were HVeAg-negative. Of all patients, 87.57% had a viral load > 2000 IU/L. Thirty-four (89.5%) HBeAg-positive patients had viral loads above the threshold of 2000IU/l and only 4 (10.5%) below 2000 IU/l. Most HBeAg-negative patients (88%) presented high viral load, in only 12% being below 2,000 IU/L (tab. I).

The prevalence of HBeAg-negative patients with viral load > 25,000 IU/l was 59.3%, compared to 63.4% of those with viral load <25,000 IU/l. There was a relationship between HBeAg antigen status and fibrosis. The fibrosis grade was correlated with viral load value (tab. II).

Fibrosis stages F2-F4 was found in 19 (50%) HBeAg-positive patients and 215 (59.3%) HBeAg-negative patients.

The prevalence of F2-F4 fibrosis in HBeAg-negative patients with viral load > 25000IU/la was 63.4% compared to 55.8% in those with viral load below this level. The prevalence of F2-F4 fibrosis in HBeAg-positive patients with viral load > 25000IU/la was 55.2%, compared to 33.5% in those with viral load below this level.

To cover all data variations in the study groups we present a Box Plot chart (fig. 2)

TABLE I

Association AgHBe – Viral load / (2000IU/l)

HbeAg			Viremia IU (2,000)		Total
			< 2,000 No/%	2,000 + No/%	No/%
HBeAg	Positive	Count	4	34	38
		% within HBeAg	10.5%	89.5%	100.0%
	Negative	Count	43	315	358
		% within HBeAg	12.0%	88.0%	100.0%
Total		Count	47	349	396
		% within HBeAg	11.9%	88.1%	100.0%

TABLE II:
Prevalence of HBeAg in the studied group according with fibrosis grade

			Fibrosis					Total
			F0 No./%	F1 No./%	F2 No./%	F3 No./%	F4 No./%	No./%
HBeAg	Positive	Count	0	19	16	3	0	38
		% within HBeAg	0.0%	50.0%	42.1%	7.9%	0.0%	100.0%
	Negative	Count	6	142	131	67	17	363
		% within HBeAg	1.7%	39.1%	36.1%	18.5%	4.7%	100.0%
Total		Count	6	161	147	70	17	401
		% within HBeAg	1.5%	40.1%	36.7%	17.5%	4.2%	100.0%

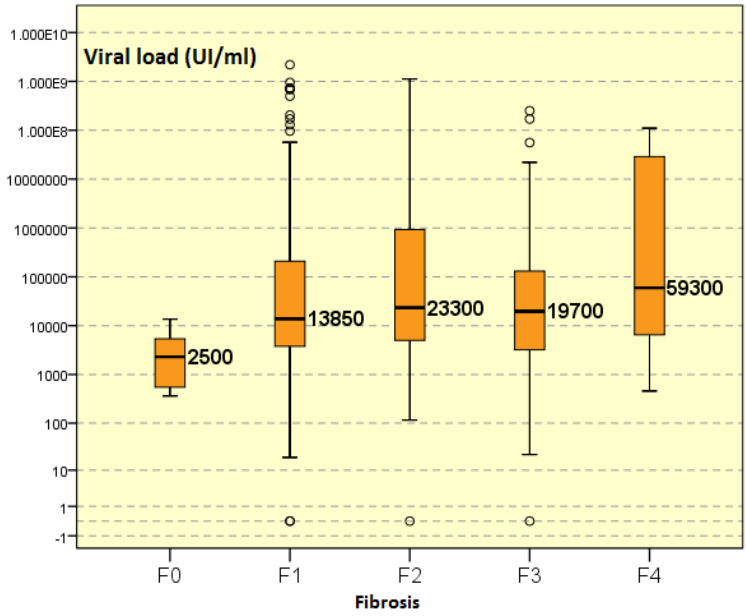

Fig. 2: Box Plot analysis for association between fibrosis and viral load.

We used the logarithmic scale because viral load had very wide variations. By Kruskal Wallis test we found statistically significant differences (p=0.027). Patients with advanced fibrosis (F4) had a significantly higher plasma viral load compared to those with early fibrosis (F0). Twenty-one patients (9.98%) had an associated hepatitis D virus infection. Of these, 17 (81%) had detectable HBV-DNA, and 9 of the (52.9%), viral load > 2000; in the remaining cases viral load was below this level. Fibrosis grade varied as follows: 9 patients (42.9%) had F1 fibrosis, 6 (28.7%) F2 fibrosis, 5 (23.8%) F3 fibrosis and one case (4.8%) F4 fibrosis. A small percentage of patients (4.98%) presented liver cirrhosis.

DISCUSSION

Previous studies (1) have demonstrated the presence in our area of Mediterranean strains characterized by the absence of HBeAg in parallel with the presence of HBV/DNA, which by the mutations in the pre-core region induce this particular profile. The presence of HBeAg in only 38 patients of our study group (9.5%), along with viral loads above the threshold of 25,000/l in 88% of the patients seem to provide evidence of this mutation which in the future needs to be certified by molecular biology studies and its genotype identified, because it is widely recognized that infections caused by genotype C are predictive for a more severe progression, with active replication and higher risk of progression to cirrhosis compared with genotype B (2, 3, 4). The prognosis of HBeAg-negative patients was better than that of HBeAg-positive patients (5).

Immune status at the time of acute infection influences the risk of chronicization. In people with impaired immune status (e.g., malignant diseases, Down syndrome, hemodialysis, transplant, HIV-positive) the risk of chronicization is significantly higher. Determination of viral load (HBV-DNA) was an important factor for assessing the stage of the disease and for monitoring the therapeutic response in chronic hepatitis B (6). Under similar conditions of exposure to HBV activity, the male sex shows a stronger tendency for HBV infection progression to persistent infection.

HBeAg-positive patients, although presenting high rates of viral replication can develop pre-core mutations (1, 3, 4). HBV viral load influences the development of liver fibrosis (7, 8). The correlation between the level of viremia and fibrosis showed that there were significant differences in viral load between patients with F0 and F4 fibrosis (on average 2500 IU/ml *vs.* 59300 IU/ml). Previously published studies show that HBV level monitoring is a better predictive indicator of infectivity than monitoring HBeAg status alone (7, 8, 9). In our study the mean values of fibrosis, F1, F2, F3 and F4 were: 6.5, 7.1, 9.1 and 19.8 kPa, respectively, similar to those obtained by Marcellin (10).

CONCLUSIONS

Chronic hepatitis B virus infection was diagnosed more frequently in young adult males. Hepatocytolisis syndrome was present with an average value of 115 IU/L. ALAT level elevation was associated with increasing prevalence of fibrosis in both HBeAg positive and HBeAg negative patients. Only a minority of patients were HBeAg-positive at the time of diagnosis. 9.98% of patients were co-infected with HDV. The correlation between the level of viral load and fibrosis showed that viral load of patients with F0 fibrosis was significantly lower than of those with F4 fibrosis. HBV viral load influenced the development of liver fibrosis. The correlation between the level of viral load and fibrosis showed significant differences between viral load and the status of HBeAg-positive or negative patients. Increased viral load levels were correlated with an increased prevalence of fibrosis, significant in HBeAg-negative patients, and in HBeAg-positive patients increased fibrosis was correlated with low viral load. The risk to of advanced fibrosis begins to increase when ALAT value is 5-times higher than normal, but it is not influenced by the high viral load value. In the future, a better monitoring of the HBV-induced chronic hepatitis cases,

alone or in association with VHD is needed in view of establishment and implementing new strategies for the prevention and treatment of HBV infection.

YOUNG PATIENTS' PERCEPTION ON DIFFERENT SURGICAL MANAGEMENT OF THE DISTO-OCLUSAL GINGIVAL OPERCULUM IN SECOND MANDIBULAR MOLARS (Abstract) **Aim**: This baseline study aims to find out the young patients' perception on different surgical management of the disto-oclusal gingival operculum in second mandibular molars: the conventional technique and the laser assisted one. **Material and Methods:** The current study included a batch of 20 patients who needed surgical bilateral removal of the disto-oclusal operculum in second mandibular molars order for them to receive conservative treatment. Each patient benefited of two different surgical techniques (laser assisted and conventional). Patients' perception towards these procedures was evaluated with a simple questionnaire. **Results:** The questionnaires were evaluated by a specialized team and the results were illustrated in the specific charts. On one hand the conventional technique wasn't perceived as very comfortable and on the other hand the laser assisted technique was very well perceived by the patients. **Conclusions:** The overall perception of young patients towards laser assisted periodontal surgery was very high and this is a means of reducing operating time and anxiety caused by the surgery itself. **Keywords**: DISTO-OCLUSAL OPERCULUM, PERCEPTION, DIODE LASER.

After Caranzza et al (1) the space between the crown of the tooth and the overlying gingival flap called operculum is an ideal area for the accumulation of food debris and bacterial growth. Although in some cases there are no clinical signs or symptoms, the gingival flap is often chronically inflamed and infected and has varying degrees of ulceration along its inner surface.

In general the acute inflammatory involvement is a constant possibility and may be exacerbated by trauma, occlusion, or a foreign body trapped underneath the tissue flap.

This is a reason why the surgical management of this soft tissue in young patients should be a contemporary preoccupation both for the periodontist and for the pediatric dentist.This baseline study aims to find out the young patients' perception on different surgical management of the disto-oclusal gingival operculum in second mandibular molars: the conventional technique and the laser assisted one.

MATERIAL AND METHODS

The current research included a sample population of 20 patients with ages between 13 and 16 years old. The patients were selected from the Department of Pediatric Dentistry and the Department of Periodontology in the University of Medicine and Pharmacy "Grigore T. Popa" from Iasi.

All the patients needed bilateral surgical removal of disto-oclusal operculum on the second mandibular molar (fig. 1, 2). This periodontal surgical procedure was needed in order to treat the cause of local inflammation and to provide proper access to the pediatric dentist for the restorative procedures on these teeth.

Every patient was surgically treated bilaterally but using different techniques. In one quadrant the patient received conventional surgical treatment and in the opposite quadrant the surgery was done using a diode laser with a 940 nm wave length and a 1.5 W energy. The surgeries were done separately, first the conventional technique and afterwards the laser assisted surgery. For safety reasons both surgeries were done under local anesthesia (fig. 3).

After the healing period of both surgeries the youngsters were asked to complete an easy questionnaire evaluating their perception regarding the two different periodontal surgical procedures and the postoperative recovery. The questionnaire was containing five questions both for the first and for the second surgery (fig. 4).

Fig. 1. Initial clinical aspect

Fig. 2. Marking of the incision line

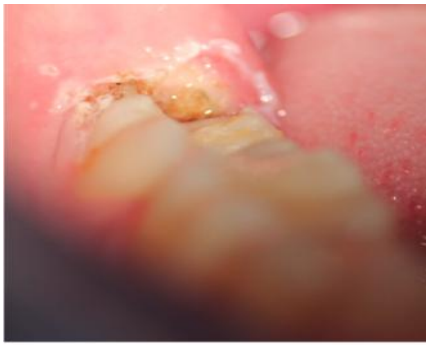

Fig. 3. Immediate post op aspect

Fig. 4. Clinical aspect 7 days after the surgery

RESULTS AND DISCUSSION

The questionnaires were evaluated by a specialized team and the results were illustrated with the help of the specific charts.

On one hand the conventional surgical technique (fig. 5) proved not to be very comfortable for the young patients and also was perceived as a source of great anxiety. Other authors claimed as well in their works that traditional gingivectomy procedures have been a challenge for dentists who confront issues of patient cooperation and discomfort (2).

On the other hand 90% of the patients reported that they felt well and excellent during the laser assisted surgery (fig. 6) which is a significantly better perception of the surgery compared to the conventional one. Other published research showed that laser soft-tissue surgery is very well accepted by children (2).

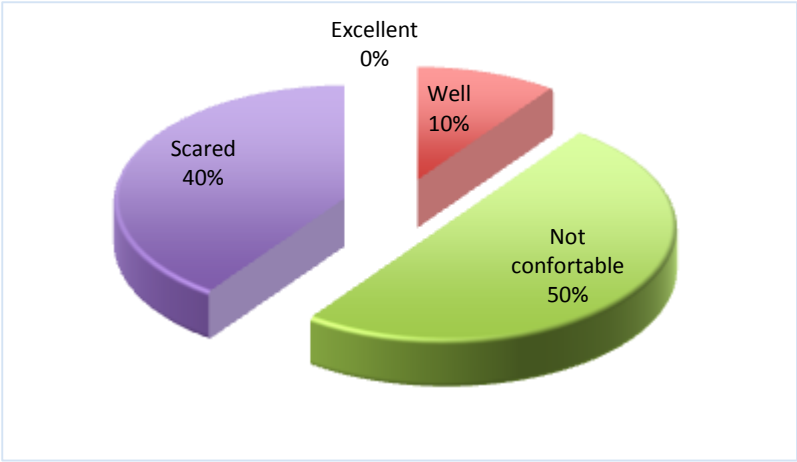

Fig. 5. Perception of comfort after the conventional surgery

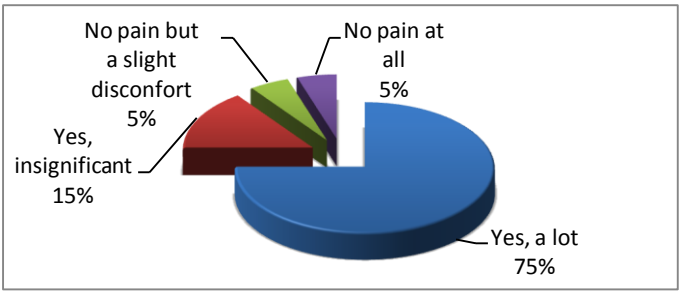

Fig.7. Perception of pain after the conventional surgery

A large majority of 75% of the patients reported that the felt a lot of pain (fig. 7) during their post operative period after the classical surgery due to the inflamed area that was removed and the scalpel cut.

The recovery period after the laser sur-

gery was perceived far better by the patients where most of them didn't experience pain but only a slight discomfort (fig. 8). The ones that reported that they felt pain said that the intensity of it was insignificant. The absence of pain can be justified by fundamental research which proved that the morphological differences identified at the gingival epithelium level and subjacent *lamina propria* support the value of laser therapy, stimulating an improved healing of the damaged tissues (3).

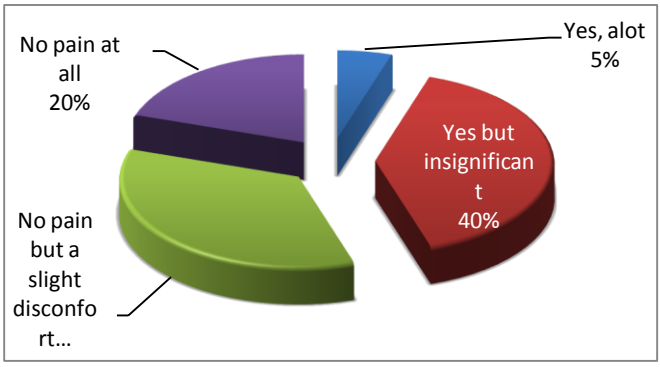

Fig. 8. Perception of pain after the second surgery

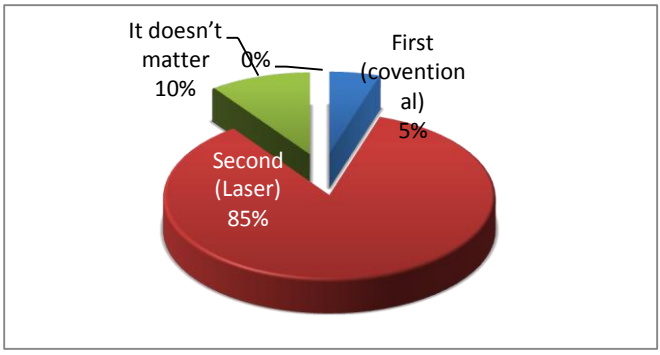

Fig. 9. Preferred treatment if the patients had to choose

If the patients had to choose between the two techniques it was shown (fig. 9) that a significant percentage of 85% would choose the laser surgery rather than the classical technique.

We do not subscribe to other authors' opinion regarding the low level of appropriateness of using diode lasers in different dental specialties (4) and we encourage this minimally invasive approach.

From the training point of view, although a diode laser was the most common type of laser used, of the eight postgraduate orthodontic programs in USA and Canada (22 percent) not offering laser training, four indicated having no plans to begin using lasers or training on their use (5).

We should focus more on implementing

the lasers in the postgraduate departments of the universities especially because of the high level of patients' perception.

CONCLUSIONS

This study confirmed that the conventional technique took the periodontist more time than the laser assisted one and this was due also to the poor cooperation of the young patients when they saw the surgical instruments. The laser assisted technique was faster and with a better cooperation from the patient's side.

The overall perception of young patients towards laser assisted periodontal surgery was very high and this is a means of reducing operating time and anxiety caused by the surgery itself.

It can be concluded that a tight cooperation should be established between the periodontist and the pediatric dentist in order to achieve optimal results both from the clinical and from the patient's perception point of view.

MICROGLIA: SCAPEGOAT, SABOTEUR, OR SOMETHING ELSE ?

Microglia is normally composed of cells which are distributed in brain and also in spinal cord, displaying a distinct immune potential. They can be mobilized and efficiently involved in a specific cellular immune monitoring activity, in case of tissular injuries or specific neurological diseases. The common opinion that the activation of microglia is neurotoxic is widely accepted, but it seems that the most dramatic instance of activation is represented by prion disease. Every failure to destroy prions can transform microglia in a real saboteur which spread the disease.On the other hand, aged or sick microglial cells can not perform an adequate synaptic remodeling-these dysfunctions contribute to neurodevelopmental or psychiatric disorders. Experimental studies sustain now that microglia has distinct actions in distinct circumstances.The understanding of its role in health and disease requires new tools to explore microglia, based on fact that the CNS and the immune system are intimately connected. COMMUNICATION IN DENTAL MEDICINE: IMPORTANCE IN MOTIVATING ELDERLY DENTAL PATIENTS

Mihaela Monica Scutariu[1], Norina Forna[2]
University of Medicine and Pharmacy – "Grigore T. Popa"-Iasi
Faculty of Dental Medicine
1. Discipline of Oro-dental Diagnosis and Gerontostomatology
2. Department of Implants and Prosthetics

COMMUNICATION IN DENTAL MEDICINE: IMPORTANCE IN MOTIVATING ELDERLY DENTAL PATIENTS (Abstract). Dental services for elderly patients are characterized by a series of particularities related to the vulnerability of this age group, which is affected by various co morbidities, and the diminished physical, cognitive and financial capacities. Finding ways to keep elderly patients coming to a dental office is possible by improving the dentist-patient relationship and implicitly the quality of care by increasing the self-esteem of the elderly and their place in society, by increasing the role of oral health in the quality of life, and here we refer to the pleasure of eating, the pleasant physical aspect and normal diction. The present paper presents the psychological aspects that interfere in the communication process between the dentist and the elderly patient and the changes motivation undergoes when people are in pain. These data can sometimes change the reticent attitude of the dentist towards the elderly patient which is often considered to be a risk patient.
Keywords: DENTIST-PATIENT DIALOGUE, MEDICAL CONSULTATION, COMMUNICATION, MOTIVATION, ELDERLY

Ageing is a continuous, gradual process which begins at birth and continues over the lifespan. It represents the irreversible inherent progressive alteration of many body functions which cannot be eliminated and which increases the individual vulnerability. Ageing presents both positive and negative aspects. These is not a specific age to clearly mark the beginning of old age, but the phenomena related to ageing are widely presented in the literature dealing with this subject, although the mechanism by which the human body is getting older is not clearly known, yet.

Generally, the ageing processes affect differently the structure and the functions of various organs and tissues. The modifications refer to either the degradation of anatomic structures accompanied by the survival of others which are provided with a compensatory activity, as it is the case of nephrons or muscle fibers, or by the continuous loss of neurons, followed by the gradual decrease of sensitive-sensory and behavioral abilities.

The particularities of the third age have lead to the necessity of organizing departments of Gerontostomatology within the schools of dentistry. This way, dentists will become familiar with the specific features of the dental services for seniors. Moreover, it appears that dental care for other age

groups has a certain impact on the elderly patient too; it is considered that if teeth are properly cared from childhood the better the oral hygiene will be later on in life, because the lack of dental hygiene affects teeth more than the process of ageing (1).

The fall out of teeth is more frequent at the level of the upper jaw, consequence of dental caries or periodontal disease. Water fluoridation and better oral hygiene, reducing the frequency of caries and buccodental infections can avoid or delay edentation in the elderly. The process of dental degradation affects both the enamel, which becomes pigmented and gradually lost through attrition, and the dentine, whose odontoblastic activity reduces the pulp cavity up to complete obstruction. To these, the weakened periodontal ligaments, gingival atrophy and bone resorption at the level of the alveolar area are added.

The oral mucosa presents a certain degree of atrophy and dryness due to the low quantity of mucin and saliva. The filiform and circumvallate papillae on the surface of atrophic tongue decrease taste sensibility by almost 30% by the age of 70.

If we refer to the elderly, during the process of oral care, the patients are not the only ones who must be motivated, but the dentists as well since their attitude towards the elderly often reflects the negative stereotypes society has in their respects (2). This attitude is represented by the refuse to treat the elderly patient, seen as a high risk patient due to the numerous co morbidities, or because the various dental procedures have to do more with removing than with preserving, extraction, with its mutilating effects, being chosen over treatment. In the young population, edentation is the oral affection with the highest impact on self-esteem, and it plays an important role in patient motivation. If dentists were familiarized with the physical and psychological features of ageing, they would no longer consider third age patients as part of the less important cases.

The dentist has the moral and professional duty to create, from the first contact and during the entire process of examination and care, the best climate for cooperation, based on transmitting a feeling of confidence regarding the positive evolution of the disease, patient's healing and his family and social reintegration. Self-esteem (behavior and attitude) stands at the base of the doctor-patient relationship and it represents the first condition for therapeutic success.

For humans, communication represents the main mean of socializing, his personality being structured in his own communication area.

The purpose of communication is that of making the interlocutor feel, think or act in a certain way. The purpose exists even if the partners of communication are not conscious of it (3).

Within the doctor-patient communication relationship, the doctor must be able to recognize and properly decipher the patient's verbal and nonverbal messages; to use the proper verbal and nonverbal communication means for transmitting information to the patient, depending on the nature of the message and context (severity of the disease, type of patient, emergency etc.) (4).

The essence of communication consists in eliminating patient's and doctor's uncertainty regarding the nature of the disease; clinical uncertainties (when there is clear uncertainty regarding the diagnosis and its prognosis) and functional uncertainties (when the doctor knows both the diagnosis

and the prognosis, but he keeps the patient and his family in a state of uncertainty for not being forced to reveal unpleasant information to the patient).

Dental medicine must become an active part in knowing the oral involutive physiological and pathological processes for being capable of creating geriatric prevention programs.

PATIENT MOTIVATION

Patient motivation is one of the least understood aspects of treatment but also one of most importance.

The components of the motivational system are numerous and vary in their origin, way of satisfaction, and functions. Human motivation includes needs, reasons, interests, convictions, tendencies, intentions, desires, and aspirations. The elements indicating a state of physiological or psychological unbalance are the tendencies. They are experienced as states of agitation, inner alert, tension (5).

If an obstacle prevents a need from being satisfied, then a state of tension appears; this is called frustration. The answers to frustration are different, the most frequent one being represented by aggressiveness. Frustration is unavoidable in psychic life; when moderated, it has positive effects on the development of personality. Thus, the impossibility of fulfilling love due to social status differences can stimulate the fight for climbing the social hierarchy. Given the unavoidable nature of frustration, balanced personalities manifest tolerance to frustration, supporting, within certain limits, states of intense tension without developing pathological behaviors.

Quite often, patient motivation is wrongly understood as the technique which changes patient behavior and not a change in patient perception of treatment importance and impact. The main idea is to reach that phase in which after becoming aware, the patient manages to motivate himself; this can be achieved if the clinician uses and stresses the right words in order to achieve a dramatic impact on patient's psychic.

One of the difficulties encountered in motivating the patient is that certain words mean different things depending on the person, and many times patients in need of motivation are those who do not need many instructions. What they need is not motivation, but the reason for which the doctor has given them those instructions.

THE BASIC STRUCTURE OF MOTIVATION

For achieving the desired result of a certain action, it is compulsory for that action to be determined by a reason. The patient must be aware that the action is right for achieving the desired result. Although the patient may be aware of these things, inner feelings may interfere with the motivational process, attitudes which influence the decision of taking action or not, so that in the end the decision will depend on inner or environmental factors.

Failure of motivation can rely on the existence of various aspects with weak structure and which can be disintegrated (6). For example, patients who do not want to change the way they perform their oral hygiene but who pretend to do it.

The positive influence on the patient could be obtained by advising him about the correct oral hygiene, identifying the reasons for which the patient is reticent, and the transformation of the doctor into a psychologist who understands the patient.

The doctor, as a good psychologist, will

get close to the patient in the latter's best interest. The doctor's affective openness towards the patient eliminates anxiety and uncertainty and humanizes the medical act.

Each patient has his own personal reasons for performing a correct brushing, and the doctor can make sure the patient maintains a correct oral hygiene. The confidence in diagnosis can be reached using a large variety of methods, from the simplest to the most complex, but in general, the diagnosis is set after a good relationship is created between the doctor and his patient.

The internal influences which affect motivation include the patient's feelings and attitude. If the patient has tried and managed to improve his oral hygiene, then the patient is more confident in the concept of oral hygiene. If the patient realizes that he plays an important part in any type of communication with the doctor, he will provide positive feed-back. Generally speaking, the patient's attitude is the result of other frequently underestimated experiences and which can influence motivation.

External influences are probably the most important, and the patient's motivation in maintaining the action or modifying the behavior depends of life style, inner pressure and the influence of the external environment.

There are three key concepts which will be taken into consideration for the best result possible: communication, environment and attitude.

Communication plays an important role in motivating the patient. It represents the ability of communicating with the patient for stimulating behavioral changes. If the patient initiates a change in his behavior, he must be helped by the clinician to obtain the expected effect. In fewer words, communication requires knowing personal attitudes and also the ability of listening to others.

The importance of the environment - apart from the feelings of both parties there is the physical situation of the patient in the dental chair frequently in decubitus, a position seen as uncomfortable and stressful. A consequence of this uncomfortable position is the fact that the patient is no longer interested in listening and understanding the advices received.

The position at the same level will give the possibility to achieve a positive result in motivating the patient. The non-verbal language will be considered as well: body language, smell, noise.

Attitude. Improving the motivational aspect is a job of the entire medical team, the purpose being sometimes difficult or even impossible to achieve. One monitoring method could be represented by the use of forms and indices systems. Thus, the patient is informed about the necessity of these measurements and the need of maintaining their values. After recording the indices, they are presented to the patient at each visit having thus the possibility to analyze the patient's effort and the results achieved.

In case the patient does not respect the indications provided, in time he will notice the appearance of complications and he will be interested in remedying the situation. Because the indices used are highly sensitive, the patient will notice the situation improves and he will be more confident with the treatment and the positive solution of his disorder.

The "self-assessment" *concept* implies encouraging the patient to monitor himself at home.

State of mind is an important element as far as quality of life is considered. Elderly

people, although they don't recognize it, are unhappy because they have lost their social status, are no longer important and respected. Elderly people realize that with the passage of time they lose the importance they once had in their social relations, due to the fact that they are no longer that active in fulfilling their role in society. Slowly, they lose the role of parents, they withdraw, suffer from chronic diseases and they must deal with the conditions imposes by their new status of pensioners.

Sadness can easily be considered a characteristic of old age. Nevertheless, this does not mean it has to be ignored. Many times elderly people are so sad that they no longer take care of themselves and thus they hurry their end; some of them even decide to commit suicide. Deficitary oral health for the elderly patient can be due to the anxiety caused by painful medical interventions, uncertainty regarding their physical aspect but also to the social isolation in which elderly people often live (7).

Another aspect of the elderly patient's motivation in improving the communication with the dentist is represented by the need of maintaining the integrity of his oral health, determined by social and psychological factors. At more advanced ages, when the work volume decreases, eating becomes one of the few pleasures of life (8). At the same time, contemporary society promotes youth, prolonged also through plastic surgery. Apart from the aesthetic consequences, oral rehabilitation facilitates a clear pronunciation, far from the nasal incomprehensible speech which is maliciously associated to old age. That is why, the number of remaining teeth, the use of prostheses or not, the level of education, social status and rural or urban native environment influence the frequency with which elderly people come to the dentist's office.

CONCLUSIONS

Motivation is an inner process and not an imperative which can be imposed from the outside, and communication creates the bridge between the two, doctor and patient.

Unlike the young patient, elderly patients tend to avoid discussing with the doctor subjects related to their emotional states as they consider a consultation to be referring strictly to solving medical problems; they do not see the doctor willing to approach this kind of subjects or they consider these discussions as a violation of their privacy. The increased severity of oral affections and the difficult access to medical services, caused by either health issues or difficult financial condition which came along with retirement, turn the elderly patient into a vulnerable category. Hence, the psychological aspects become key elements in the medical act addressed to elderly patients.

TOPICAL XYLITOL ADMINISTRATION BY PARENTS FOR THE PROMOTION OF ORAL HEALTH IN INFANTS: A CARIES PREVENTION EXPERIMENT AT A FINNISH PUBLIC HEALTH CENTRE

Xylitol has been shown to be an effective tooth decay preventive agent. Clinical studies of xylitol have almost exclusively involved chewing gum or lozenges and evaluated school age children and tooth decay in permanent teeth. This demonstration programme tested topical use of xylitol as a possible oral health promoting regimen in infants at a Finnish Public Health Centre in 2002-2011. Parents (usually mothers) began once- or twice-daily administration of a 45% solution of xylitol (2.96 m) onto all available deciduous teeth of their children at the age of approximately 6-8 months. The treatment (xylitol swabbing), which continued till the age of approximately 36 months (total duration 26-28 months), was carried out using cotton swabs or a children's toothbrush; the approximate daily xylitol usage was 13.5 mg per each deciduous tooth. At the age of 7 years, caries data on the deciduous dentition of 80 children were compared with those obtained from similar, untreated children (n = 90). Xylitol swabbing resulted in a significant ($P < 0.001$) reduction in the incidence of enamel and dentine caries compared with the comparison subjects (relative risk 2.1 and 4.0, respectively; 95% confidence intervals 1.42-3.09 and 2.01-7.98, respectively). Similar findings were obtained when the children were 5 or 6 years old. The treatment reduced the need of tooth filling relative risk and 95% confidence intervals at 7 years: 11.86 and 6.36-22.10, respectively; $P < 0.001$). Compared with untreated subjects, the oral counts of mutans streptococci were reduced significantly ($P < 0.001$). Considerable improvement in dental health was accomplished in infants participating in a topical at-home xylitol administration experiment, which was offered to families in the area by the Public Health Centre as a supplement to standard oral health care. This study is the first to demonstrate that xylitol topical syrup at 8 g per day divided into two or three doses given during primary tooth eruption in children 15 to 25 months of age reduces tooth decay and could prevent up to 70 percent of decayed teeth. Caregiver assessment of the programme was mostly rated as high or satisfactory (Mäkinen KK, Järvinen KL, Anttila CH, Luntamo LM, Vahlberg T. Topical xylitol administration by parents for the promotion of oral health in infants: a caries prevention experiment at a Finnish Public Health Centre. *Int Dent J* 2013; 63(4): 210-224).

PREDICTORS OF QUANTITATIVE MICROBIOLOGICAL ANALYSIS OF SPATTER AND AEROSOLIZATION DURING SCALING

D. Şerban[1], Ancuţa Banu[2], Costela Şerban[3], Ioana Tuţă-Sas[4], Brigitha Vlaicu[4]

Predictors of quantitative microbiological analysis of spatter and aerosolization during scaling (Abstract): **The aim** of this study is to analyze the infection risk through spatter and aerosolization during scaling and to create a prediction model of the total number of hemolytic bacteria. **Material and methods:** Air samples were collected prior to patient's arrival and spatter and aerosol samples were collected during scaling procedure in 80 patients of 4 different dental clinics. The dentists calculated DI, CI, DMFT. Only patients with CI>=1 were included. The bacteriological results (CFU/m^3) were correlated with clinical indicators. Patients were divided into 2 groups: one that rinse with sterile water and the other with chlohexidinemouthrinse 0.1%. **Results and conclusions:** Medium size effect positive correlations were found between the number of decayed teeth and the total number of bacteria and the total number of hemolytic bacteria that grew on plate attached to the dentist's mask. The mean number of bacteria and the mean number of hemolytic bacteria that grew on plate attached to the dentist's mask were significantly lower in the group that rinse with chlorhexidine 0.1%, when compared to the group that rinsed with sterile water. When controlling for the total number of bacteria and the total number of hemolytic bacteria from air sampling, the total number of hemolytic bacteria that grew on the plate attached to the dentist's mask can be predicted by CI, group membership and DMFT score. **Keywords:** SPATER, AEROSOLS, HEMOLYTIC BACTERIA.

For dentists and oral health personnel there is a high risk of contamination with several communicable diseases, due to particularities of their work. Ultrasonic scalers are being used extensive in dental practice for the removing of dental plaque and calculus. Several authors have confirmed presence of bacteria in dental calculus (1, 2, 3, 4). Microbial aerosols are produced by ultrasonic scalers have a high risk of infection because they can contain microorganisms of oral cavity, including microbes from calculus, respiratory tract and blood, that can be carried through the aerosolisation and can contaminate skin, oral, nasal and eye membranes (5, 6). The microorganisms incriminated to be transmitted from patients through aerosolization could be Gram positive and Gram negative bacteria (7), viruses such as hepatitis B virus (HBV), hepatitis C virus (HCV), Herpes B virus, human immunodeficiency

virus (HIV), fungi and prions (8).

Regarding the exposure of dentists to aerosols, studies conducted in 1980-1995 had found higher concentrations of antigen and antibodies of HBV (9, 10) and HCV (11) than in general population. More recently other authors (12) had found significant increases in CFU/m^3 in air samples taken before the procedure and after the procedure in patient proximity. Rautemaa et al. (13) had found significant contamination at all distances sampled when high-speed instruments were used. They did not find higher densities in patient's close proximity. Gram-positive cocci, namely viridans streptococci and staphylococci, were the most common findings.

The aim of this study is to analyze the infection risk through spatter and aerosolization during scaling and to create a prediction model of the total number of hemolytic bacteria using patient's clinical features.

MATERIAL AND METHODS

The study included 4 dental practices and in the analysis were included 80 patients with a Calculus Index >=1. The patients were selected in a prior visit. These patients represented the first patient of the working day, after 12 hours lack of activity.

Air samples were taken before the patient arrived on different Petri plates that contained three different culture media: agar, blood agar and Sabouraud. For air sampling we used M.A.Q.S (Microbiological air quality sampler - Oxoid). The air is sucked by the turbine through a perforated filter. Air flow is directed to the Petri plate, situated under the grill. The air volume is 100 l/minute and for each sample is recommended the sampling of maximum 1.000 liters of air. Exciding this quantity will dehydrate the surface of Petri plate.

Another sample was taken during scaling on a blood agar culture plate attached to the dentist's mask.

Patients were divided into 2 groups and were randomized by order of arrival in the practice: one group that rinse with sterile water, and a group of patients that rinsed with an alcohol-free clorhexidine 0.1% mouth-rinse.

The DMFT, DI and CI were calculated by the dentist, respecting the WHO indication from 1997 (14, 15), after the patient sat on the dental chair. After this procedure, the dentist placed the mask that had a Petri plate attached and begun the intervention. When the intervention was over, the Petri plate was detached, and then covered. All plates were labeled and transported to the Microbiology laboratory. All plates were incubated 24 hours at 37°C. We used the following bacteriological indicators: the total number of bacteria (UFC/m^3), and the total number of hemolytic bacteria (UFC/m^3). The intervention consisted of scaling with an ultrasonic scaler.

Data were processed using IMB SPSS version 18 (2010). For the parametric correlation of data, Pearson's correlation was used. T-Tests were used in order to compare between study groups the number of CFU/m^3 (total and hemolytic) that grew on the plate placed on the operator's mask. For the prediction of the number of hemolytic CFU/m^3 that grew on the plate placed on the operator's mask we used the multiple hierarchal regression.

RESULTS AND DISCUSSION

Females represented 52.5% of total study population. Age range was between 20 and 65 years. Mean group age is 42.74 +/- 12.38 years, with median at 45 years. Mean DMFT score for the whole group was

21.3 +/- 4.94, with a minimum of 9 and a maximum of 28. We have found a significant positive correlation between DMFT score and the total number of bacteria ($r=0.37$, $p<0.01$), and between DMFT score and the number of hemolytic bacteria ($r=0.39$, $p<0.01$) that grew on the Petri plate that was attached to the operator's mask. Size effect of both correlation is small ($r^2=0.14$, respective $r^2=0.15$). Stronger correlations were found when using the decayed number of teeth with the total number of bacteria ($r=0.62$, $p<0.01$) and the total number of hemolytic bacteria ($r=0.57$, $p<0.01$) and the size effect of latter correlations is medium.

In accordance to our results, Korean researchers (16) found that the reduced glutathione level, a major endogenous antioxidant produced by the cells, showed a significant linear relationship with the salivary Lactobacilli level ($p=0.016$), DMFT score ($p=0.005$). In contrary to our results, Mannaa et al. (17) used a pooled supragingival plaque sample per participant, obtained from posterior approximal sites and analyzed it for 15 bacterial species using the checkerboard DNA-DNA hybridization technique, did not find significant relationships between the bacterial scores and DMFT/dmft nor D/d groups.

Mean DI score for the whole group was 0.28 +/- 0.27 with a minimum of 0 and a maximum of 1.0. Mean CI score for the whole group was 2.02 +/- 0.71 with a minimum of 1.0 and a maximum of 3.0.

The results of air sampling prior to intervention indicated that the mean number of bacteria that grew on the plate was 118.01 +/- 25.07 CFU/m^3 and the mean number of hemolytic bacteria that grew on the plate was 10.68 +/- 4.75 CFU/m^3.

Similar results were published by Azari et al. (18), that the total bacterial counts in the air of dental surgery rooms and in non-surgery rooms without direct involvements with dental operations were in the range of 120-280 CFU/m^3 and 49-128 CFU/m^3 respectively. Other Romanian researchers (19) had published similar results for the mean value for the total number of germs at the beginning of the day in the air was 129 CFU/m^3.

We have found that the mean total number of bacteria on the mask attached Petri plate were significantly lower in the group of patients that rinsed with chlorhexidine0.1% ($M=66.25$), when compared with the group that rinsed with sterile water ($M=121.35$ CFU/m^3) $t(78)=-5.37$, $p<0.001$ and size effect $\varepsilon=0.26$ is considered large according to Cohen. The mean number of hemolytic bacteria on the mask attached Petri plate were significantly lower in the group of patients that rinsed with chlorhexidine ($M=9.03$), when compared with the group that rinsed with sterile water ($M=15.78$ CFU/m^3) $t(78)=-6,75$, $p<0.001$ and size effect $\varepsilon=0.36$ is considered large according to Cohen.

In agreement to our study, Reddy et al. (20) when investigated the reduction of bacterial aerosol contamination during use of ultrasonic scaler comparing the efficacy of sterile water rinse with non-tempered chlorhexidine rinse and with a tempered chlorhexidine mouth rinse and found significant reductions in CFU in the group that used non-tempered chlorhexidine rinse when compared to the group that rise with sterile water. Similar results were obtained by Konig et al. (21) when they used cold (18°C) rinse versus wormed rinse (37°C), with better results for wormed solution of chlorhexidine. In a study by Rosin (22), that compared the effects in bacterial re-

duction of placebo *vs.* a chlorhexidine 0.12% rinse, the authors obtained significant reduction in bacterial count in the chlorhexidine 0.12% rinse group.

Multiple hierarchical regression was used to assess the ability of 4 measures (the group membership, the Debris Index and the Calculus Index, DMFT) to predict the number of hemolytic bacteria that grew on the plate attached to the dentist's mask, after controlling for the influence of total number of bacteria and the number of hemolytic bacteria cultivated from aerosols of the dental office, prior to intervention. Preliminary analyses were conducted in order to ensure no violation of the assumptions of normality, multicollinearity, homoscedasticity. In the first step, total number of bacteria and the number of hemolytic bacteria were included and the model containing these variables was not statistically significant. In the second step, besides total number of bacteria and the number of hemolytic bacteria we introduced the group membership, the Debris Index and the Calculus Index, DMFT. This model as a whole explains 69. 7% of the variance of total number of hemolytic bacteria $F(6.79)=27.9$, $p<0.001$. CI has the highest beta value (beta=0.71, $p<0.001$), followed by the membership to the group that rinsed with sterile water before the intervention with beta=0.19, $p<0.05$ and DMFT with beta=0.18, $p<0.05$. The unique variance explained by the significant predictors was 61.1% for CI, 15.8% for group membership and 15.7 for the DMFT score.

DI, total number of bacteria and the total number of hemolytic bacteria from air sampling did not contribute significantly to the model.

Prediction equation:Number of hemolytic bacteria that grew on the plate attached to the dentist's mask = -8.71 + 2.85 x sterile water group + 7.51 x CI + 0.28 x DMFT.

TABLE I

Regression coefficients for the prediction of predict the total number of hemolytic bacteria that grew on the plate attached to the dentist's mask

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	17.847	4.268		4.181	.000
	Total number of hemolytic bacteria from air initial	-.065	.181	-.041	-.360	.720
	Total number of bacteria initial from air	-.040	.034	-.134	-1.169	.246
2	(Constant)	-8.711	3.663		-2.378	.020
	Total number of hemolytic bacteria initial	-.082	.104	-.052	-.788	.433
	Total number of bacteria initial	-.025	.020	-.082	-1.247	.216
	Sterile water group	2.851	1.162	.190	2.452	.017
	DI	-2.155	2.444	-.079	-.882	.381
	CI	7.517	.793	.709	9.473	.000
	DMFT	.281	.115	.185	2.435	.017

CONCLUSIONS

Small size effect positive correlations were found between DMFT score and the total number of bacteria and the number of hemolytic bacteria that grew on plate attached to the dentist's mask. Medium size effect positive correlations were found between the number of decayed teeth and the total number of bacteria and the total number of hemolytic bacteria that grew on plate attached to the dentist's mask.

The mean number of bacteria and of hemolytic bacteria that grew on plate attached to the dentist's mask were significantly lower in the group that rinse with chlorhexidine 0.1%, when compared to the group that rinsed with sterile water.

When controlling for the total number of bacteria and the total number of hemolytic bacteria from air sampling, the total number of hemolytic bacteria that grew on the plate attached to the dentist's mask can be predicted by CI, group membership and DMFT score.

Simple measures like the prior rinse with a chlorhexidine 0.1% mouth rinse reduces bacterial counts in the mouth and implicit the number of aerosolized microbes. The level of calculus is also a predictor of the quantity of aerosolized bacteria. Decayed teeth maintain a higher level of microbial flora that translates to a higher quantity of aerosolized microbes.

ANTICANCER ACTIVITY OF *SCLEROCARYA BIRREA*

Sclerocarya birrea is used in traditional medicine for the treatment of many diseases. A study performed by Tanih *et al.* aimed to scientifically prove its therapeutic properties. For this reason, water and acetone extracts of *S. birrea* were evaluated in terms of their anti-cancer activity on HT-29, HeLa and MCF-7 cell lines. The methods used included: cell titre blue viability assay in 96-well plates was used, acridine orange and propidium iodide staining for evaluation of apoptosis, and scanning electron microscopy for morphological examination of the treated cells. The study showed remarkable antiproliferative activities of the acetone extract of *S. birrea.* Also, the extract exerted apoptotic potential against MCF-7-treated cells. The study concludes that *S. birrea* could be very useful in anticancer therapy (Tanih NF, Ndip RN.The Acetone Extract of *Sclerocarya birrea* (Anacardiaceae) Possesses Antiproliferative and Apoptotic Potential against Human Breast Cancer Cell Lines (MCF-7). *ScientificWorldJournal* 2013; 2013: 956206 doi: 10.1155/2013/956206).

INCIDENCE AND PREVALENCE OF DENTAL-PERIODONTAL CONDITIONS AND EDENTATION IN MOLDAVIA (Abstract): The proper rehabilitation of the partially extended edentulous patient should lead to a state of balance between the components of the stomatognathic system and the therapeutic option selected for an as long as possible. **Aim:** To outline the importance of a holistic biological perspective on the body-stomatognathic system relationships and the need for complex rehabilitation in view of obtaining a long lasting balance. **Material and methods:** 3340 individuals from urban and rural areas of Iasi County were evaluated. The evaluation was based on the correlation of physical exam with data from a specially drafted questionnaire aimed at determining oral health behavior pattern, a sine-qua-non condition for a clear identification of oral conditions specific to the study area. **Results:** General health status was poor in 72.1% of the subjects from rural areas as compared to 27.9% in those from rural areas, with cardiovascular diseases ranking first but with higher rates in urban than in rural areas. In urban areas, odontal lesions were the most common and had a higher prevalence in 2012 than in the previous years, followed by the periodontal lesions with the same ascending trend in 2012. **Conclusions: C**ontinuity with regard to the prophylaxis of general and oral conditions in the Iasi County in both rural and urban areas is a must, health education being essential for improving population health.
Keywords: POPULATIONAL SCREENING, EDENTULOUS RATE, GENERAL STATUS, ORAL PATOLOGY.

The treatment of edentulous patient involves the application in his/her oral cavity of certain artificial substitutes for restoring the morphological continuity of the dento-alveolar ridges and the functions of the stomatognathic system affected by edentation (1).

The tolerance of the components of the stomatognathic system to the contact with artificial substitutes – prostheses is a complex challenge (2).

The proper rehabilitation of the partially extended edentulous patient should lead to a state of balance between the elements of the stomatognathic system and the therapeutic option selected for as long as possible (3).

This study aimed at outlining the importance of a holistic biological perspective on relationships between the body and the stomatognathic system and the necessity of a complex rehabilitation in view of reaching a long lasting balance.

This study was focused on determining

the incidence and prevalence of odonto-periodontal conditions and edentation accompanied by various complications in the Moldavian territory.

MATERIAL AND METHODS

The 4th Edition of the Oral and General Diseases Prophylaxis Caravan, an already traditional event that started in 2009, took place in Iasi and other towns on May 22, 2012.

On this occasion, 3,340 individuals from urban and rural areas of Iasi County were evaluated. The female gender was prevalent (62% from urban and 55.4% from rural areas). Most subjects from urban areas (54.3%) were retired, while school-going population (43.9%) was prevalent in rural areas.

The evaluation consisted in the correlation of physical exam findings with the data from a specially drafted questionnaire aimed at determining the oral health behavior pattern, a sine-qua-non condition for a clear reflection of oral conditions specific to the study areas (4, 5).

RESULTS

General health status was poor in 72.1% of the subjects from urban areas as compared to 27.9% in the rural areas (fig. 1).

Cardiovascular diseases ranked first but with higher rates in urban than in rural areas.

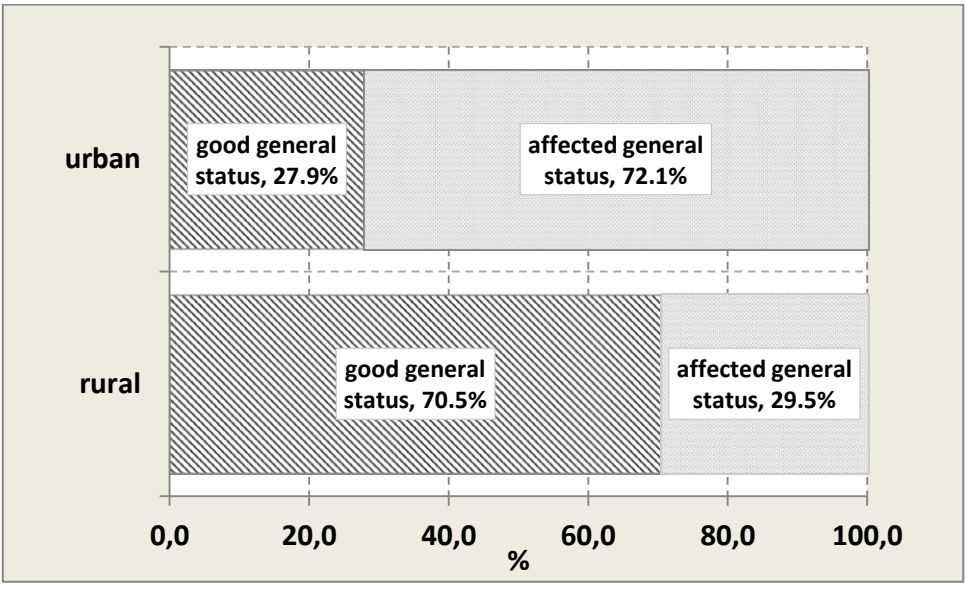

Fig. 1. General health status of the study population

Following the dynamic evolution during the whole time span of the caravan, an increase in the incidence of cardiovascular diseases starting from 19.1% in 2009, to 21.3% in 2010, 37.4% in 2011 and 42.2% in 2012 was found (fig. 2).

In the rural areas (fig. 2), further deterioration of the general health status from 2010 to 2012 was also noticed, cardiovascular diseases being the most common, followed by liver and neurologic diseases and diabetes.

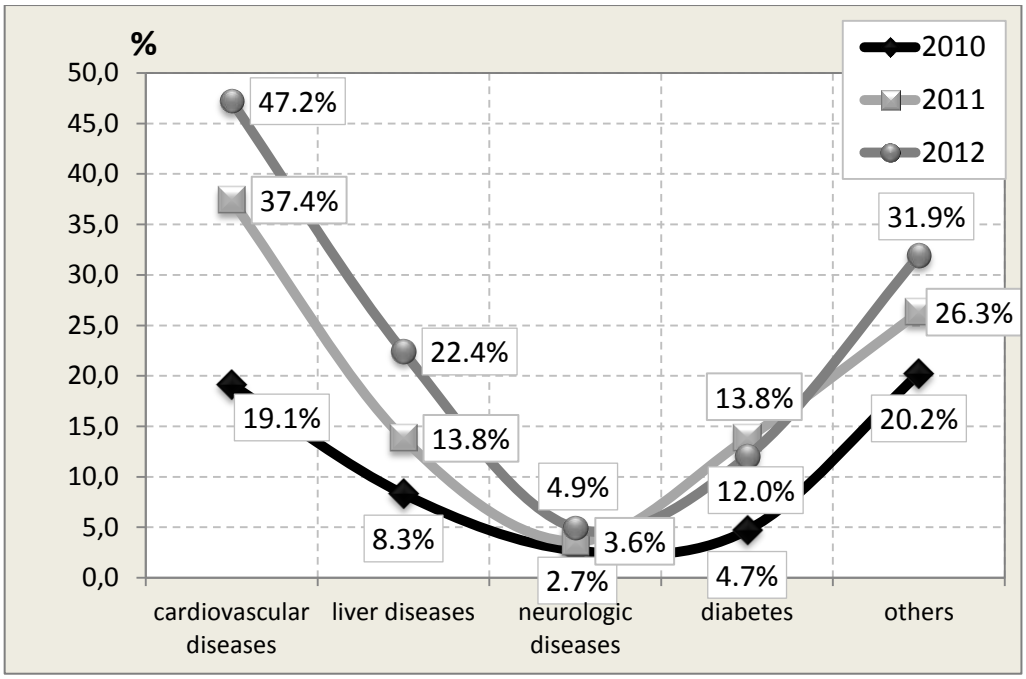

Fig. 2. City of IASI - General Pathology 2010 - 2012

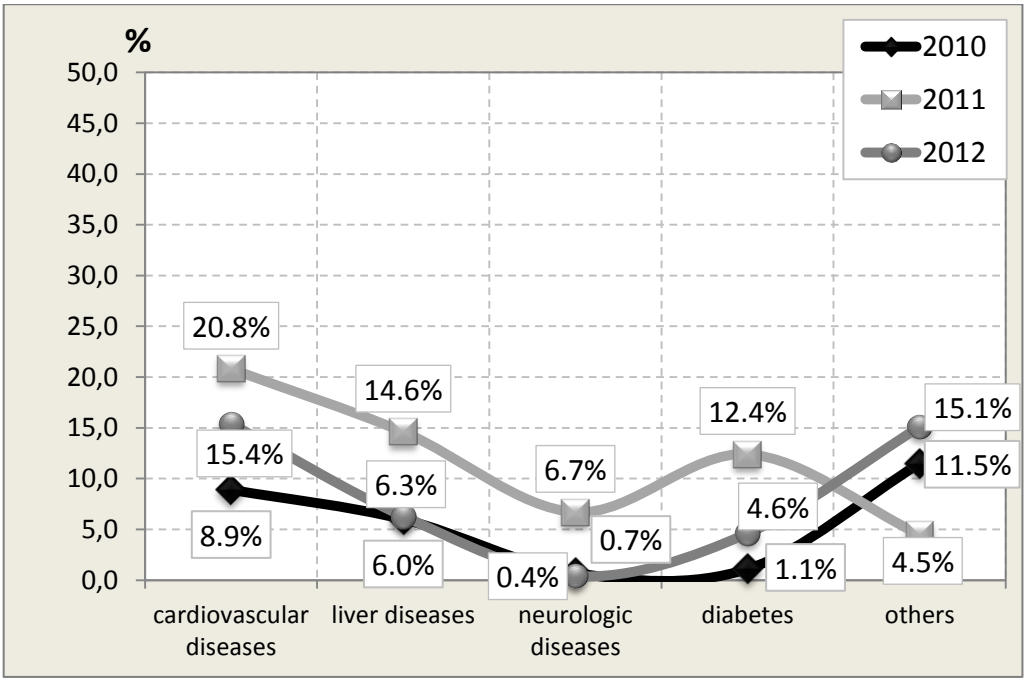

Fig. 3. Rural Area - General Pathology 2010 - 2012

The year 2012 gives a clear image on the prevalence of local oral pathology in the Iasi county (urban and rural areas), the odontal and periodontal lesions reaching significant prevalence rates of 74.7% in rural areas and 67,2% in the urban ones (fig. 4, 5).

In 2012, the prevalence of oral conditions in the urban areas of Iasi County was high, odontal lesions followed by periodontal lesions being the most common and sharing the same ascending trend.

In rural areas, the prevalence of oral conditions fluctuated, with a highest of 74.7% in 2012 for odontal lesions, while fistulas were found in small percentages, relatively equal for the 3 study years (fig. 5).

As to the type of edentation, the partially reduced edentation was prevalent, both in the urban and rural areas, 43.7%, and 22.1%, respectively. Following the dynamic of edentation during the 3 study years, the incidence of partially reduced edentation is increasing, calling attention to the need of treatment for this clinical entity.

In rural areas an obvious increase in the incidence of partially reduced and extended edentation was found in 2012 as compared to the previous years, so the need for both fixed and removable dentures will increase.

As to the therapy of edentation, in 2012 there was an increased prevalence of fixed restorations, followed by removable dentures, reaching 40.8% in urban areas as compared to 18.9% in rural areas. We also need to underline that 74.7% of the rural population does not need prosthetic therapy, while the same applies to only 39.9% of the urban population.

Regarding the use of oral hygiene products, in rural areas toothpaste is used by 94.0%, mouthwash by 18.9% and dental floss by 3.9% as compared to 97.2%, 41.4% and 11%, respectively in urban areas (fig. 6).

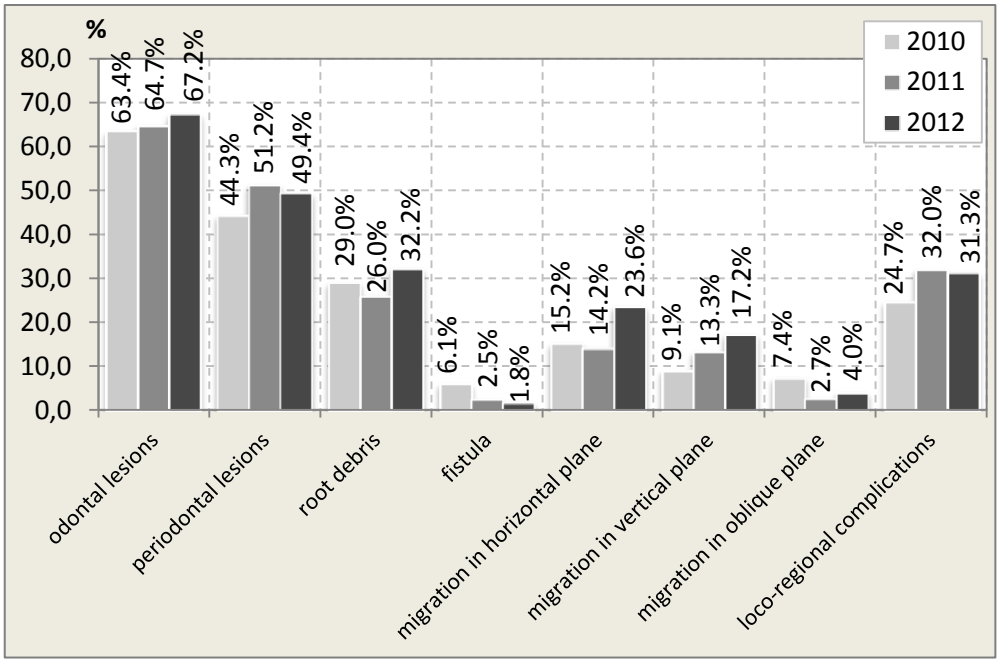

Fig. 4. Local pathology - City of Iasi 2010-2012

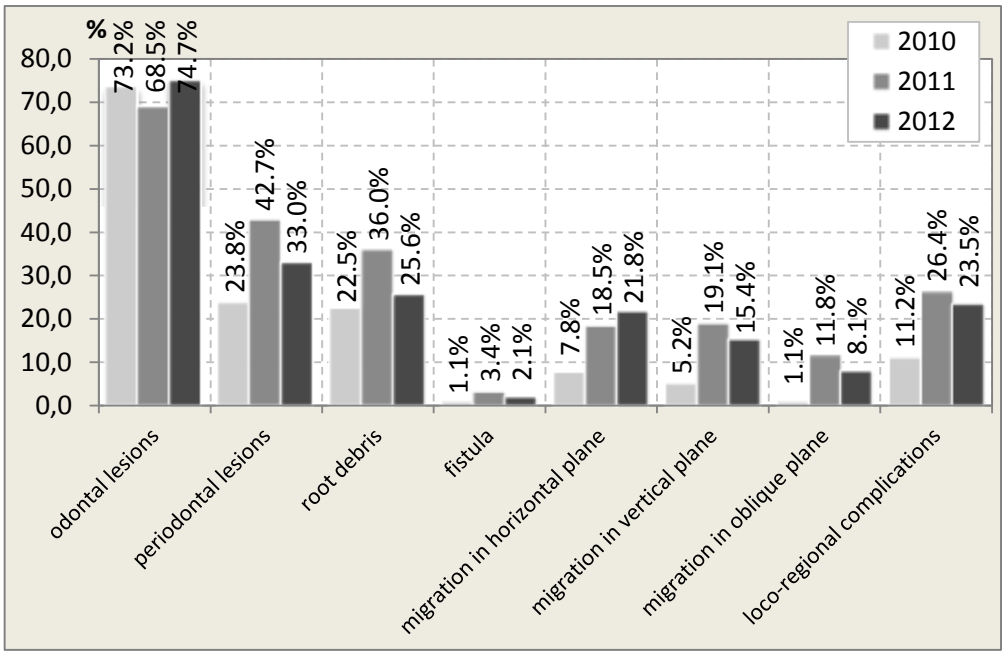

Fig. 5. Local pathology - Rural Area 2010-2012

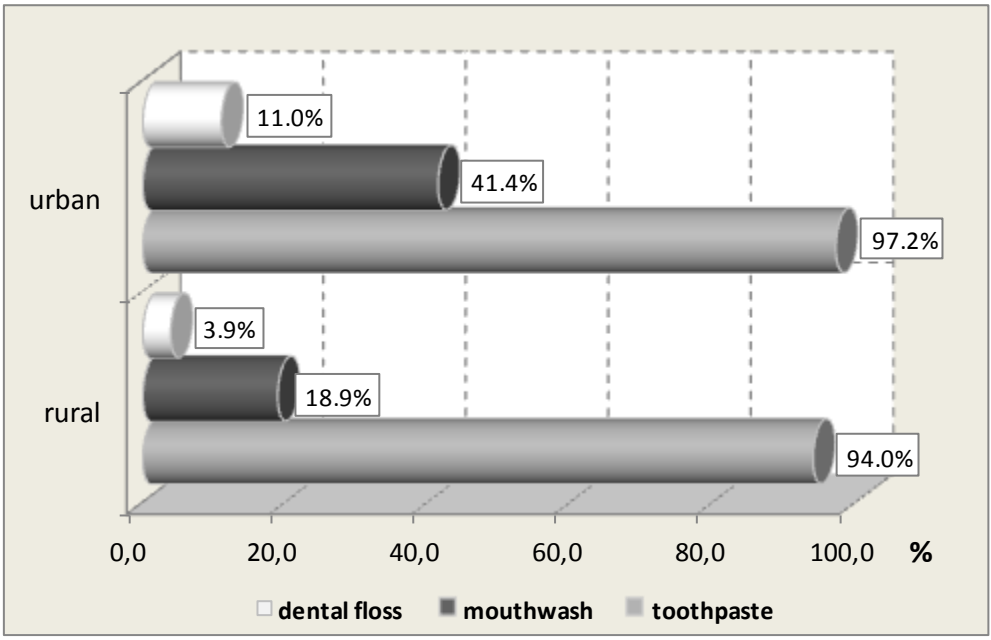

Fig. 6. The use of oral hygiene products in urban and rural areas

As to oral hygiene, 50.9% of the urban population and 42.1% of the rural one clean their teeth twice a day (fig. 7). Toothbrush is changed by 22.8% of the rural population of Iasi County once a year, while 31.6% of the urban population does so 4 times a year (fig. 8).

Following the dynamics of oral hygiene in the study population, the improvement in health education resulted in that more and more people brush their teeth more than once a day and use auxiliary oral products, but toothbrushes are replaced less often in both rural and urban areas.

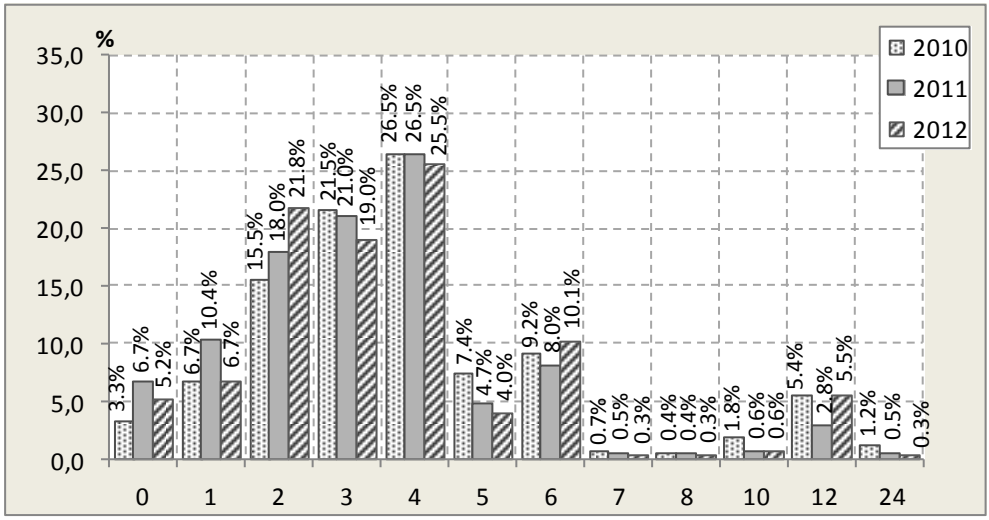

Fig. 7. City of Iasi – Number of toothbrush replacements per year (2010 – 2012)

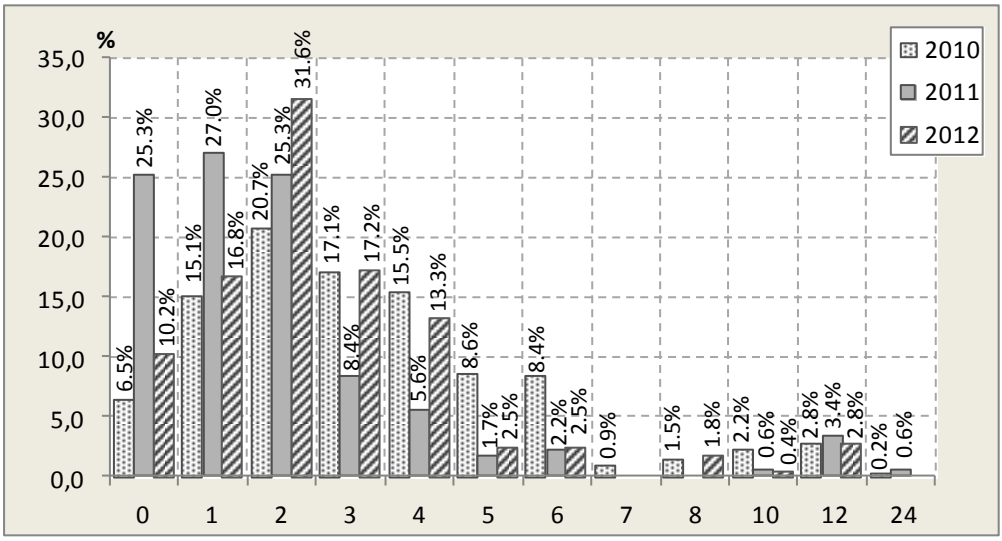

Fig. 8. Rural area – Number of toothbrush replacements per year 2010 - 2012

With regard to the number of dental visits, starting with 2009 there was a steady increase in the number of "when in need" visits", a worrying trend of possible local and loco-regional complications.

CONCLUSIONS

As a result of attending the activities of the caravan, more and more people gained better access to health education and care, oral hygiene products, learned correct tooth brushing techniques, and understood that neglect of health can have long-term effects on health and well-being.

Continuity of the prophylaxis of general and oral conditions in the Iasi county, both in the rural and the urban areas is a must, health education playing an essential role in health promotion and improvement process.

DIABETES IN THE COMPETITIVE ATHLETE

Athletes with diabetes range from the athlete participating in various youth sports to competitive olympic athlete and present a significant challenge to themselves and the medical staff who care for them on a daily basis. Each sport and the type of exercise have their own effects on diabetes management with numerous factors that significantly affect glucose levels, including stress, level of hydration, the rate of glycogenolysis and gloconeogenesis and the secretion of counter-regulatory hormones. An american research team from University of Missouri – Kansas City School of Medecine provides in this article a general overview of diabetes mellitus, the effects of exercise on glucose levels and a detailed review of the potential complications encountered in the management of diabetes in the athlete (Harris GD, White RD, Diabetes in the Competitive Athlete, *J Voice*, 2012, 26, 1: 44-50)

SPECIFIC FEATURES OF THE STROMAL OVARIAN TUMORS

Ramona Mircea[1], E. Anton[2], Carmen Anton[3], Cristina Tărniceriu[1], A. H. Nedelcu[1] Florentina Zenovia Pricop[2]

3. Discipline of Medical Semiology IGH

CHARACTERISTICS OF THE STROMAL OVARIAN TUMORS (Abstract): **Aim of the study:** establishing a characteristic pattern for the stromal ovarian tumors. **Material and methods:** we realized the clinical-statistics analyze of 27 stromal tumors (lot B) from a total of 498 patients with ovarian tumors (lot A), diagnosed and treated between 1999 – 2008 in Elena Doamna Hospital of Obstetrics and Gynecology, Iasi. We used the clinical files of these patients, operatory protocols and anatomopathological results. **Results:** we analyzed a large number of parameters: age, location, first diagnoses, symptoms, anatomopathological diagnose, imunohistochemical diagnose, etc. When we compared the two lots of patients we pointed out significant differences for the following parameters: most affected group of age, first diagnose, and associated diseases, anatomopathological and imunohistochemical differences, and prognostic factors. **Conclusions:** stromal ovarian tumors are a less studied entity, with particular anatomopathological and imunohistochemical features which differentiates them from the rest of the ovarian tumors. **Keywords:** OVARIAN CARCINOMA, TUMOR, BIOMARKER

The malignity of stromal ovarian tumors is somehow between the same characteristics as in the case of the epithelial tumors. Based on histological grading it will be appreciated the tumoral invasion, short term prognostic, type of surgical procedure and its necessity, future oncologic protocol (1, 3, 4, 6, 7).

The interaction between tumor and ovarian stroma is an insufficient aspect of ovarian tumorogenesis. Tumoral aria, including stromal fibroblasts, infiltrative stromal cells, vascular and lymphatic network and extracellular matrix is an integrated part of carcinogenetic process, promoting cellular growth and metastatic disorders (1, 2, 5).

Stromal alterations which accompany the tumoral progression include breaches in basal membrane which surrounds the tumor, severe immune response and angiogenesis (new vascular network). Additional breakdowns of the mesenchymal connective tissue surrounding the tumor can also be noted (6, 7, 9, 10, 11). These changes resemble a lot with tissular response observed during the healing of wounds through fibrosis (8, 10, 11). Fibroblasts and their role in tumorogenesis are considered to be the new target in the development of

new therapies for the tumoral stroma (10, 11), tumor associated fibroblasts or their disturbed environment (8, 10).

Unfortunately today we have less information regarding the stromal ovarian fibroblastic activation because of the lack of a performant experimental research system.

Our study recognizes the implication of a double interaction between neoplasic cells and ovarian peritumoral stroma, demonstrating their relationship in sustaining and promoting the tumoral invasion. After the analyze of the two lots of patients and the correlation of data with the medical literature we realized a protocol based on the conclusions of this study.

MATERIAL AND METHODS

This personal study was realized in multiple directions (anatomical, clinical, statistical and anatomopathological) using the following components: *1.* we realized a retrospective study on 498 patients hospitalized in Clinical Hospital of Obstetrics and Gynecology **"**Elena Doamna**"** Iasi, between 1.01.1999 – 31.12.2008. The lot of 498 patients with ovarian pathology was selected from the total of 8898 general gynecological pathology; *2.* lot A represents all patients diagnosed with ovarian tumors, meaning all 498 cases; *3.* lot B represents patients with stromal ovarian pathology, selected from all cases; *4.* microscopic study was realized on paraffin included specimens selected from the lots of study (we selected patients from all groups of age with/without other associated pathology); *5.* macroscopic histopathological study followed the macroscopic aspect of all tumors, local extension, stages; *6.* microscopic histopathological study evaluated the specimens colored with HE for establishing the diagnose of organ and after that anatomopathological diagnose; *7.* imunohistochemical study used an indirect tristadial method and a panel of 5 antibodies: ER (estrogen receptor), PR (progesterone receptor), S100 (protein S100), SMA (smooth muscle actin) and Caldesmon. We realized dosage for 18 ovaries (for ovarian tumors in generally) and for 3 stromal ovarian tumors; *8.* Statistic analyze used many methods: *t-Student* test, test χ^2**,** relative risk, predictive value and tendency. Data was followed up and charged with statistic functions from *Excel* and *EpiInfo*.

RESULTS AND DISCUSSION

Lot A contains all 498 cases of ovarian pathology, representing 5.6% from all 8898 patients with gynecological pathology hospitalized between 1999-2008. Lot B contains 27 stromal and sex cords ovarian tumors: 7 granulosa tumors (one bilateral and one cystic) (26%), 11 ovarian fibromas (41%), one ovarian thecoma (4%), 5 ovarian fibrothecomas (18%), 3 ovarian mixomas (11%).

The distribution on group of age for lot A reveals: highest frequency for group 31-40 years (26.51%), closely followed by group 41-50 years (21.08%). For lot B the age average is 45.5 years, between the intervals 22-69 years. The result is congruent with the result from group A, 45.94 ± 15.68 years (t-Student=0,15; dF=496; p>0.05). The distribution on group of age for lot B reveals following aspects: highest frequency: 41-50 years (33.33%), followed by group 51-60 years (22.23%); the rest of the groups do not have frequency variations, each of the containing four cases (14.8%).

Comparing the associated co morbidities we can highlight a difference between the two lots: for lot A most associated were

cardiovascular diseases (30.8%), and for lot B genital pathology (47%).

Comparing clinical diagnose for the two lots we pointed out the following elements: patients from lot A had associated pain (100%), while lot B 98%; bleeding for lot A: 0.6% and for lot B: 28%.

For stromal ovarian tumors we followed many steps for ultrasound exam also: we wanted to correlate the ultrasound aspect with the histological subtype of the tumor; increased echogenity with posterior shadow suggested ovarian fibroma while diffuse echogenity without posterior shadow was correlated with pure thecoma; echodense tumors, without posterior shadow suggested fibrothecoma.

The analyze of CA 125: lot A revealed following aspects: malignant tumors had average values (163.63 ± 143.08 UI/ml) for stage II, borderline tumors had average values (39.59 ± 10.0 UI/ml) for stage I, benign tumors had average values (27.21 ± 18.22 UI/ml) for normal interval. Only one teratoma was evaluated (66.5 UI/ml). Stromal tumors were most of the cases in stage I (96± 106 UI/ml). For lot B we pointed out the following aspects: granulosa tumors had average values (111.6 ± 75.4 UI/ml) for stage I, for the rest of the tumor types the values were under the limit of 35 UI/ml (tab. I).

TABLE I

Correlation matrix of average values for CA 125 for different stromal ovarian tumors (test t-Student)

Tumors	granuloasa (n=7)	ovarian fibroma (n=11)	ovarian thecoma (n=1)	fibrothecom (n=5)
ovarian fibroma (n=11)	2.56 ($p<0.05$)	-		
ovarian thecoma (n=1)	2.95 ($p<0.05$)	2.54 ($p<0.05$)	-	
fibrothecom (n=5)	2.85 ($p<0.05$)	1.39 ($p>0.05$)	-	-
mixom (n=3)	3.10 ($p<0.05$)	3.57 ($p<0,01$)	0.43 ($p>0.05$)	1.36 ($p>0.05$)

We dosed CA125 for the patients with clinical and ultrasound suspicion of neoplasic tumor. We had values inside the normal interval but also very increased values, over 400 UI/ml. The evolutive stages of malignant tumors for which CA125 was positive were in most of the cases terminal stages, with distance and epiplonic dissemination.

Macroscopic anatomopathological exam offered important details regarding the aspect of the tumor, shape, consistence, colour. The lab dissection of the specimenes revealed the inside aspect, described the content (color, aspect, consistence, volume), septum and intratumoral vegetations.

Microscopic anatomopathological exam pointed out the invasion of ovarian stroma in benign and malign tumoral processes. The histological fragments were prelevated from different ovarian sites.

Imunohistochemical evaluation of ovarian tumors was used to point out the response of ovarian stromal cells to a specific marker. We followed both the ovarian tu-

mors in general and stromal ovarian tumors in particular and also the stromal reaction from the peritumoral area.

The main stromal reaction during a tumoral process is the stromal hyperplasia. Physiologically this is also increased with age. We choose to identify the stromal reaction in other types of ovarian tumors also, because we wanted to frame these changes in the global context of ovarian pathology. For *struma ovarii* ER was intense positive in stromal cell's nucleus from the peritumoral ovarian tissue and was negative in thyroid tissue (epithelial cells and stroma also). For serous cystic adenomas ER was positive in epithelial cells, weakly positive and moderate positive in nuclei from adjacent ovarian stroma. There were also cases when ER was not positive at all inside the stroma (fig. 1, 2).

For mucinous adenocarcinoma ER was negative in tumoral stroma and nuclei of epithelial tumoral cells but positive in peritumoral ovarian stroma (fig. 3, 4).

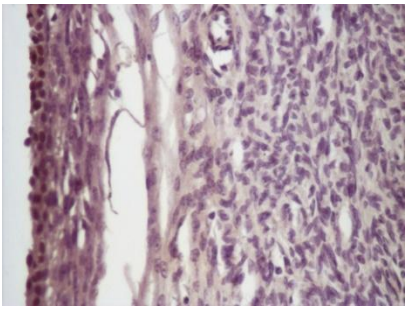

Fig. 1. ER (+) in epithelial cells, negative stroma

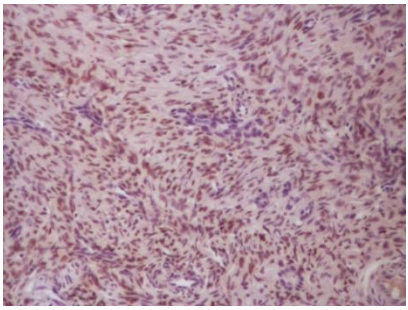

Fig. 2. Weak focal and moderate ER (+) stroma

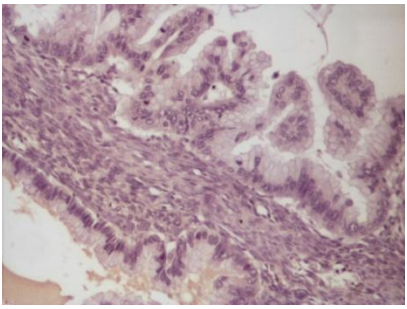

Fig. 3. ER (-) in tumoral tissue

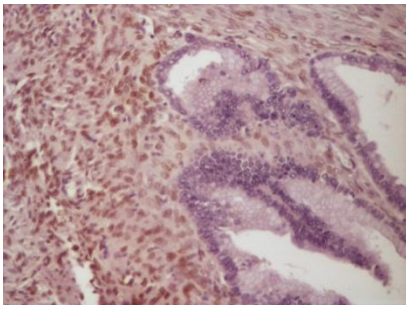

Fig. 4. ER (+) in tumoral stroma

For ovarian fibrothecoma ER was focal positive in tumoral stroma and negative in adjacent ovarian stroma (fig. 5, 6).

PR imunohistochemical detections were done especially in the nuclei. PR concentration for all groups of study was similar. It was detected inside nuclei, cystic invaginations developed from the isolation of invaginated epithelium, metaplastic epithelium and ovarian stroma. PR concentration was not dependent to menopause instalation.

For mucinous ovarian adenocarcinoma, PR was focal positive in tumoral stroma and negative in tumoral epithelial cells; and also positive in nontumoral ovarian stroma.

For cystic adenocarcinomas PR was negative in tumoral stroma and positive in nuclei of tumoral epithelial cells for one case and negative in tumor and focal weakly positive in stroma in the other case (fig. 7, 8, 9, 10).

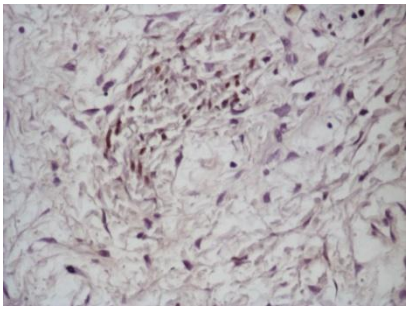

Fig. 5. ER(+) focal

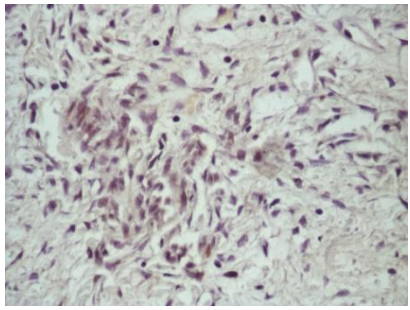

Fig. 6. ER increased (+) focal

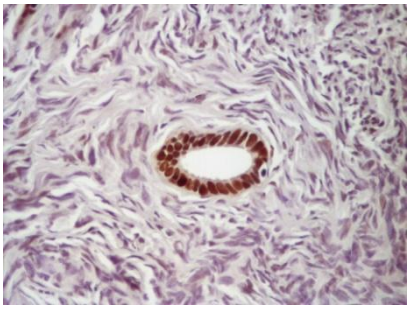

Fig. 7. Hiperplasic stroma with PR (-)

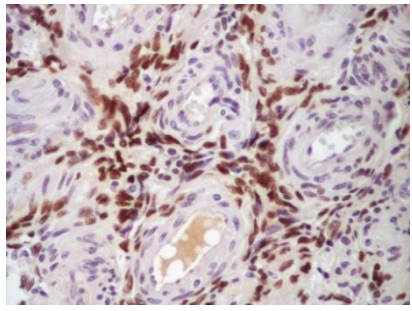

Fig. 8. Intense PR(+) medular stroma

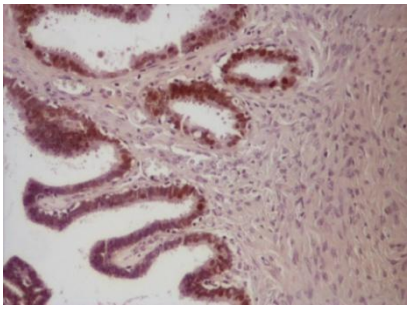

Fig. 9. PR intense (+) in the tumoral epithelium

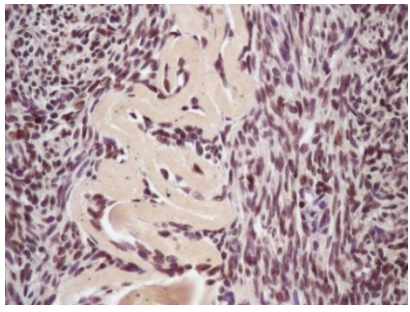

Fig. 10. Ovarian stroma weakly PR (+)

For ovarian fibrothecoma PR was positive in different degrees inside tumoral stroma and also inside adjacent stromal tissue.

For the dosage of SMA inside *struma ovarii* was negative inside epithelial tumoral cells and positive in tumoral stroma. In the extratumoral stroma SMA was also positive, same as vascular walls and other smooth muscular fibers. For the mucinous ovarian adenocarcinoma SMA was positive

in tumoral stroma and negative in epithelial tumoral cells. Inside normal stroma SMA is lightly positive, positive in vascular walls and other smooth muscular fibers. Fibrothecal tumoral cells were also intense positive for SMA (fig. 11, 12, 13, 14).

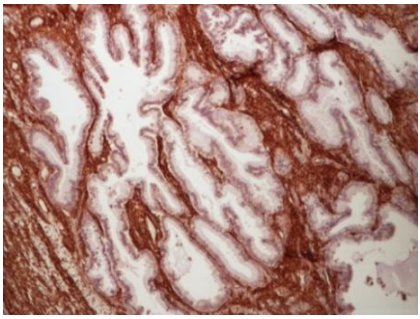

Fig. 11. SMA intense (+) inside tumoral stroma

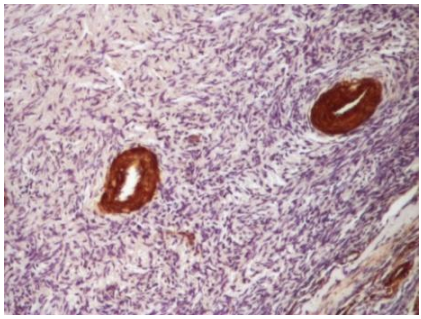

Fig. 12. SMA(-) inside ovarian stroma

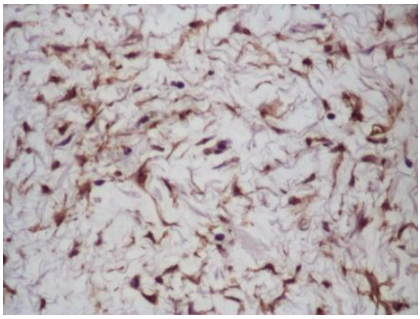

Fig. 13. SMA intense (+) tumoral cells

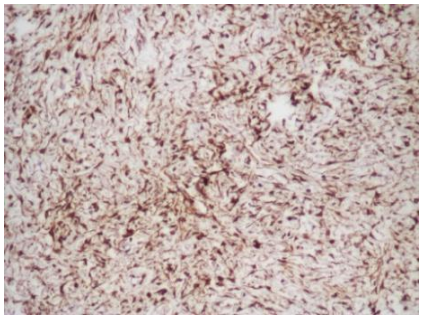

Fig. 14. SMA intense (+) tumoral cells

Nuclear expression of S100 in different stages is correlated with the aggressiveness of an ovarian cancer, autocrine and paracrine conditions playing a main role in the determination of the aggressiveness of ovarian neoplasic cells. For the studied ovarian stroma S100 was negative in the selected cases, we had only cases with positive intern marker such as small amielinic nervous fibers (fig. 15, 16).

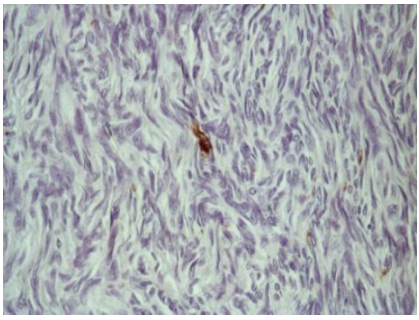

Fig. 15. S100 (-) in ovarian stroma

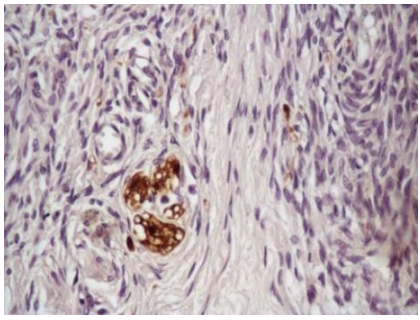

Fig. 16. S100 (-) in ovarian stroma

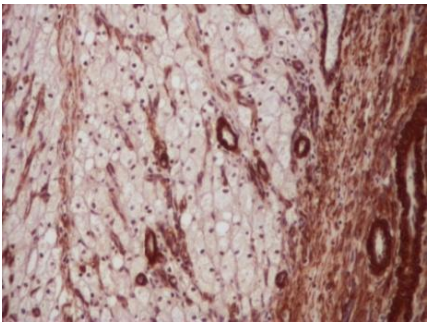

Fig. 17. Caldesmon (+) stroma

Fig. 18. Caldesmon intense (+) tumoral cells

Caldesmon dosage revealed variable results and was positive mainly inside stromal ovarian tumors but also inside tumoral stroma and adjacent peritumoral stroma from other types of tumors (fig. 17, 18).

CONCLUSIONS

The increasement of stromal network installed with age determined the reduction of vascular support. The tumoral progression also induces the multiplication of the stromal network. Our study developed on two lots of patients pointed general epidemiologic parameters, statistic differences for clinical, paraclinical and anatomopathological diagnose for both categories.

We pointed a frequent positivity for ER inside the ovarian stroma, in all types of tumors not only for those with main stromal component. The figures we presented demonstrated the behavior of ovarian stroma for ER in general, for all groups of age.

We noticed the overexpression of estrogen and progesteron receptors in ovarian stroma from the ovaries with fields of stromal thecal hyperplasia both nodular and diffuse.

For the current medical practice we can suggest the utility of SMA dosage for certitude histological diagnosis of ovarian tumors. We did not remark the necessity of usage of S100 for the differentiation of ovarian tumors for both lots. The positivity of ovarian stroma for Caldesmon is obvious especially for stromal tumors. In this case we also noted the positivity of the adjacent stroma and vascular stromal elements. We also noted the negativity of this marker for epithelial components and epithelial originated tumors. To conclude, Caldesmon can be used for the diagnosis of ovarian stromal tumors.

NEWS

ELAFIN-EXPRESSING BACTERIA, BENEFICIAL FOR INFLAMMATORY BOWEL DISEASE

In a study by Motta *et al*, the intestinal mucosal expression of Elafin, a natural protease inhibitor, was determined in patients with inflammatory bowel disease. It was found that Elafin expression is diminished in those patients. Elafin has anti-inflammatory properties proved both *in vitro* and in animal models. Lactic acid bacteria were engineered to express and deliver Elafin to the inflammation site in colon. In mouse models of acute and chronic colitis, oral administration of lactic acid bacteria secreting Elafin decreased intestinal inflammation. In cultures of human intestinal epithelial cells treated with lactic acid bacteria expressing Elafin, the epithelium was protected from increased intestinal permeability and the release of cytokines or chemokines, which suggests that oral delivery of such bacteria could be useful in treatement of inflammatory bowel disease (Motta JP, Bermudez-Humaran LG, Deraison C *et al*. Food-Grade Bacteria Expressing Elafin Protect Against Inflammation and Restore Colon Homeostasis. Science Translational Medicine 2012; 4 (158): 158ra144 DOI: 10.1126/scitranslmed.3004212).

LISFRANC MIDFOOT DISLOCATIONS: CORRELATIONS BETWEEN SURGICAL TREATMENT AND FUNCTIONAL OUTCOMES (Abstract): Lisfranc dislocations and fracture dislocations are the most common severe injuries of the foot. **Aim:** To assess the functional outcome of patients with Lisfranc dislocations of the midfoot by applying the latest methods of diagnosis and treatment. **Material and methods:** The study reviewed 31 patients with dislocations and fracture- dislocations of the Lisfranc joint over a 10 years period. The average follow-up period was 44 months (range 12 - 108). Injuries were classified according to Myerson scale. **Results:** The outcomes were evaluated using the Baltimore Painful Foot score (PFS) and American Orthopaedic Foot and Ankle Society (AOFAS) mid-foot scoring scale. 10 patients had an excellent outcome on the PFS scale, 8 were classified as good, 13 fair and poor. The average AOFAS score for the midfoot, used for results interpretation was 72 (range 52-92). **Conclusions:** Of all methods of surgical treatment used, the highest scores were obtained by internal fixation with screws. Eight patients (25.8 %) developed posttraumatic arthritis of the tarsometatarsal joints. **Key words:** TARSOMETATARSAL DISLOCATION, LISFRANC JOINT, INTERNAL FIXATION, FUNCTIONAL OUTCOME

Lisfranc injury is relatively rare, with an incidence variously reported between one per 5,500 fractures per year (1), one per 60,000 populations per year (2)_or accounting for 0.2% of all fractures (3). This term is used in present to describe a large spectrum of posttraumatic injuries of the midtarsal region of the foot (1). Diagnosis is aided by high-quality radiographs (AP, 30° oblique and lateral views). Diagnosis is often overlooked, especially in the multiply injured patient with other distracting injuries (3, 4), which can significantly reduce outcome (2) with resultant long-term disability (5, 6). A spontaneous partial or complete relocation is not unusual (4, 7) and may complicate accurate assessment. A high index of suspicion must be maintained for these injuries, and additional imaging, stress radiographs (2), weight-bearing radiographs (6), CT (8, 11) or MRI (4) performed as indicated.

Although some controversy exists about the optimal method of treatment (6, 8, 10, 12) most authors now advocate anatomic reduction with internal fixation as the

treatment method of choice (2, 13, 14). The internal fixation methods of Lisfranc midfoot injuries were exposed in The Manual of Internal Fixation (7), recommended by Association of Osteosynthesis (AO). Although pin fixation has their own supporters (3), the postoperative and functional outcomes have a relatively high failures rate (7). This study reviews the outcome of Lisfranc midfoot injuries treated by different methods. In addition, it attempts to determine whether there is a correlation between traditional physician-based outcome and patient based outcomes in order to establish a benchmark for future assessments (3, 11).

MATERIAL AND METHODS

We conducted a preliminary study on a series of 31 patients with Lisfranc tarsometatarsal fracture-dislocations, investigated and operated between January 1, 2001 and 31 of December 2010 in the Orthopedic Unit of the Suceava Emergency County Hospital, Romania. A historical retrospective study was performed and all case notes and radiographs were examined. Data was collected from patient charts under the following headings: age, gender, date of injury, side of injury, delay in diagnosis, mechanism of injury, classification of injury, associated injuries, treatment method, method of wound closure and any resultant complications. Injuries were classified on reviewing the initial radiographs according to the scale proposed by Myerson (14). The patients were evaluated in terms of postoperative course, incidence of early and late complications, functional outcome of surgery, depending on the severity of injuries and treatment methods applied. A descriptive statistical analysis and a correlation study were conducted in order to evaluate the relation between different internal fixation methods and functional outcome scores at 3 and 6 months following surgery. Outcome instruments used were the Baltimore Painful Foot score (PFS) (14) and the American Orthopaedic Foot and Ankle Society (AOFAS) mid-foot scoring scale (9).

RESULTS

The annual incidence of Lisfranc injuries kept increasing especially in the last 4 study years, culminating in 2010 with 5 cases out of 2100 admissions to our unit. Age distribution of the 31 patients available for follow-up was 18 to 67 years (mean age 39 years). There were 19 male (61.3 %) and 12 female patients (38.7 %). Left foot was involved in 18 patients and the right in 13. In one patient with multiple injures a diagnosis of |Lisfranc injury was initially missed but treated within 2 weeks of the original injury. Ten patients (24%) with multiple associated injures, but only two of them in traumatic or hemorrhagic shock, were admitted to ICU for monitoring of the general condition and hemodynamic rebalancing (6, 11). Isolated foot injuries occurred in 21 patients.

The mechanism of injury was: crush injury at workplace in 4 patients; motor vehicle accident in 12 cases, motorbike accident in 7 cases („high velocity trauma": 74.2%), and in 8 cases the injury occurred during sports activities or falling from height („low velocity trauma": 25.8%). Associated injuries in polytrauma patients were: neurological trauma in 2 patients, rib fractures in 3, long bone fractures in 5, intraabdominal injuries in 1 patient. Twenty patients had associated tarsal fractures (4 cases, 12,9%), metatarsal fractures (5 cases, 16.1%), metatarso-phalangeal dislocation (1 case), with only 11 patients having

neither (35.4%). The loco-regional complications were quite common, involving the dorsalis pedis artery (n=4), the peroneal nerve (n=2), open fracture-dislocations (n=4), crushing syndrome (n=2), compartment syndrome (n=5). Twenty-nine patients had primary wound closure, and 2 secondary closures, split skin grafting being performed in 2 cases. Average follow-up was 44 months (range 12–108).

Injuries were classified according to Myerson scale. A type A1 injury was found in 9.7% (*n*=3) of the cases, type A2 in 19.3% (n=6), B1 in 6.4% (*n*=2), B2 in 12.9% (*n*=4), C1 in 32.2% (n=10), and C2 in 19.3% (*n* =6) (fig.1).

Fig. 1. Lisfranc divergent fracture dislocation type C2 Myerson

TREATMENT PRINCIPLES

The patients with closed Lisfranc mediotarsal traumas were subjected to surgery in a variable period of time that did not exceed 24 hours since their admission (12). Generally, the surgical approach was by the two longitudinal, standard incisions, recommended by the specialty literature (6). This approach was practiced in 28 patients with dislocations or midtarsal fracture–dislocations, including those who developed a compartment syndrome (5 patients), this way both syndrome diffusion (11) and open reduction and internal fixation being obtained. In 3 patients we practiced a single medial incision due to the presence of the isolated tarsal-metatarsal lesions, strictly located at the level of the internal spine (4). By this approach we have performed the open reduction and the fixation of the first three tarsal-metatarsal joints.

The surgical technique used in all the patients was that of anatomical open reduction followed by the internal fixation under direct visual control (12) by different fixation techniques. We have chosen this technique, being the most modern and accepted technique by most of the nowadays specialists (7, 13, 15).

In twenty patients (64.4%) surgery was performed between 2001 and 2008. The technique and algorithm for introducing the pins were not generally standardized. 1, 8 and 2 mm Kirschner wires were used. Usually the lesions were approached by the two previously mentioned longitudinal incisions

Between 2008 and 2010, we have tried to standardize the internal fixation according to AO-ASIF principles in 11 patients (35,6%). Therefore, we introduced internal fixation by screws, observing the internal fixation principles and algorithm in order to minimize the error rate and to ensure a generally rigid stabilization of the mediotarsal and especially of the internal spine. This algorithm strictly follows the steps recommended by the AO school (6,7), the screws being introduced after the anatomic tarsometatarsal reduction. The initial temporary fixation was done by K-wires, after the entire exposure of the lesions and their reduction through the two parallel longitudinal incisions. Fixation of the medial column was done after having tested the intercuneiform instability neutralized by screw fixation. Fixation of the lateral column

was not always necessary after the fixation of the medial column due to post-reduction secondary stability (6, 7) (in only 5 of 11 patients treated by screwing the medial column); other 4 patients (12.9%) presented only isolated lesions to the medial column, without surgically approaching the lateral column (fig.2). The associated metatarsal fractures were fixed by K-wiring in 3 patients (9.6%) or by fixation with miniplates to the comminute fractures in 2 cases (6.4%).

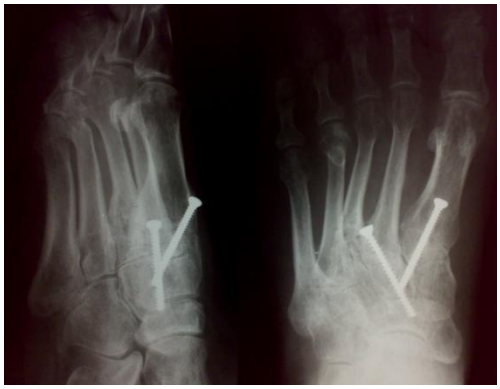

Fig. 2. Isolated injury of the medial column (type A2 Myerson) with screw fixation: radiograph images 6 month after surgery

Post-surgical care included the immobilization with well cushioned below-knee cast for a period of 6 weeks. Sutures were removed 14 to 21 days after surgery, and anticoagulation Low Molecular Weight Heparin (LMWH) treatment was extended up to 6 weeks after surgery (12).

In the patients in whom the pinning method was used, we usually chose to extend the immobilization period up to 8-10 weeks for the prevention of secondary displacements. A foot support was usually done late in the patients with pin fixation, 10-12 weeks after surgery, respectively. The osteosynthesis materials (K-wires) were usually removed 6-8 weeks (6, 14) after the immobilization period ended in 29 patients (with only pins or pins associated to screws). We have also chosen to initiate an early recovery treatment plan (at 6 weeks), with a progressive relapse of the partial foot support, followed by total foot support after 8-10 weeks (16). Algoneurodystrophic Leriche syndrome had a higher incidence (2, 4), especially in the patients with mediotarsal dislocation when the exclusive pin-fixation technique was applied. Fourteen of a total of 20 patients operated by this technique (70%) had pain, paresthesia, swelling, cyanosis of the foot, and loco-regional osteoporosis on radiographic images in the late postoperative period after plaster immobilization suppression (8 to 12 weeks) (14, 15).

The patients operated during the last three study years by stable internal fixation (screwing techniques) had a much lower incidence of Leriche syndrome as a result of lower assets (6 weeks) associated with active rehabilitation treatment (15) (2 of 11 patients developed this complication, 18.2%, respectively).

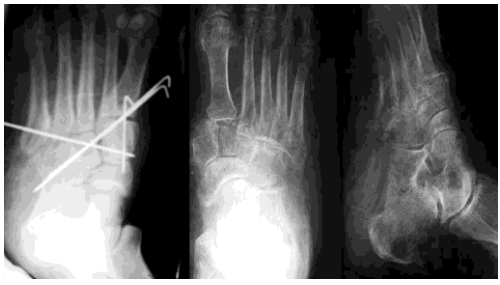

Fig. 3. Severe midfoot arthritis after Lisfranc fracture dislocation with K-wire fixing, secondary displaced (postoperative and after 6 month radiographs images).

Midtarsal osteoarthritis had a fairly high incidence (16, 17), especially in patients operated during the first study years by K-

wire fixation (fig. 3). Of these 20 patients, 6 patients developed mediotarsal osteoarthritis (30%). In the group operated with screw techniques of the medial column, only 2 of 11 patients developed midtarsal arthritis, respectively 18.2%. Overall, the incidence of posttraumatic midtarsal arthritis was 25.8% (8 patients).

DISCUSSION

The aim of the study was to review: the functional results after these injuries; which factors influence the outcomes; which surgical treatment yielded the best functional outcomes; the incidence of posttraumatic midtarsal arthritis following these injuries. Functional outcome was assessed in all patients included in the study, using the AOFAS scale for midtarsal region of the foot, developed by the American Orthopedic Foot and Ankle Society (3). This scale has three major items, pain, function and alignment, the total score being set at 100 points. Each item is scored depending on the severity of organ or functional damage). Thus, for a healthy foot, the highest score 100; the score gradually decreasing according to the functional impairment of the midtarsal region found.

We intentionally joined the group of 20 patients operated in the interval 2001-2008, who exclusively underwent internal pin fixation, with the group of 11 patients operated in 2008-2010, in which we applied stable internal fixation, according to the AO screw fixation techniques of the medial column. The functional assessment scale was administered individually to all patients. The incidence of late postoperative complications was high, especially in patients with internal pin fixation: midtarsal osteoarthritis, foot deformities, and painful neurodystrophic syndrome, as compared to the group of patients operated by means of modern internal fixation. The functional prognosis of patients with midtarsal dislocations, measured by AOFAS scale (3) is quite poor in the group of patients treated by pin fixation methods.

The end results showed an average AOFAS score of only 62 in the patients operated exclusively by pin fixation techniques, and an average AOFAS score of 90 in the group of patients operated by AO standard fixation methods. Overall, the study patients had an average AOFAS score of 72 points.

In our study, the Baltimore Painful Foot Score (12, 14), that quantifies the outcomes of the treatment measuring pain, function, gait, cosmesis and motion, the outcome was excellent (90 to 100) in 10 patients, good (75 to 90) in 8, fair (60 to75)in 8, and poor (less than 60) in 5. The average PF score was 75. There were 18 patients (58%) with good and excellent results, and 13 with fair or poor results (42%). Twenty patients with open reduction and pinning fixation performed between 2001 and 2008 had an average PF score of only 68. The reminder of 11 patients with open reduction and internal screw fixation performed between 2008 and 2010 had an average PF score of 92.

CONCLUSIONS

The treatment of these lesions should be standardized for all tarsometatarsal lesions, but with the therapeutic characteristics of open traumas, crush syndrome, or associated vasculoneural lesions (11). As a rule we applied first-intention surgical treatment with the first 24 hours, regardless of the anatomoclinical variety, comprising open anatomic reduction and screw fixation, using the screw insertion algorithm for fixing the medial column (7, 9, 11). Pin fixation of

the lateral column, of the metatarsus, or fixation with screwed-in miniplates can also be included (13). Internal fixation of the medial column using open or percutaneous pin fixation has a poor prognosis because of the high incidence of secondary displacements and posttraumatic arthritis (17), so we abandoned this technique.

Starting physical therapy immediately after the 6-8 weeks period is compulsory, progressively resuming the support function of the foot until full support at 10-12 weeks, and wearing foot ware arch cushions up to 12 months after surgery to support the arch of the foot. The goal is to lower the incidence of the complex regional pain syndrome, foot stiffness, and walking disorders (14, 15).

BEHAVIORAL INVOLVEMENT OF IMIDAZOLINE SYSTEM

M. Nechifor, Diana Ciubotariu
University of Medicine and Pharmacy "Grigore T. Popa" – Iaşi
Faculty of Dental Medicine
Pharmacology Department

BEHAVIORAL INVOLVEMENT OF IMIDAZOLINE SYSTEM (Abstract): The imidazoline system consists in imidazoline receptors I_1, I_2 and I_3 and the active as well as that there are some endogenous ligands. We consider that one of the most important functions of this system is modulation of different types of behavior. Existent data show that I_1 and I_2 receptors have different effects on some behavior components, such as suicidal behavior, stress, anxiety, food intake etc. We consider that selective I_1 and I_2 agonists could become drugs to be used in the therapy of some behavioral disorders. The fact that some agonists or antagonists of imidazoline receptors have also effect on alpha-adrenergic receptors or MAO (monoamine oxidase) enlarges the use area of the compounds in behavioral disorders. **Key words**: IMIDAZOLINE RECEPTORS I_1 AND I_2, BEHAVIOR, DEPRESSION, FOOD INGESTION

The imidazoline system consists in imidazoline receptors I_1, I_2 and I_3 and the active endogenous substances acting on them and it represents an important system for regulating the cell functions. Existing evidence show the involvement of the importance of imidazoline in modulating central nervous system (1). One of the most important natural agonists is agmatine. The imidazoline system has at least two important characteristics: some agonist and antagonists also act on the alpha-adrenergic system and agmatine is synthesized out of arginine, which is also a source of nitric oxide. One of the important endogenous systems in our body is the imidazoline system. It is known that there are two types of well-described receptors for this system (I_1 and I_2 receptors), as well as that there are some endogenous ligands. Also, there are known certain types of different effects mediated through this biological system. One of the most important fields where the imidazoline system is known to be involved in is represented by human and animal behavior. Imidazoline system is important for both normal and pathological behavior. In case of certain neurological and especially psychiatric diseases, changes in the imidazoline system balance have been detected:

a. Involvement in depression and suicidal behavior;
b. Involvement in mood disorder;
c. Involvement in stress;
d. Involvement in the locomotor activity.

DEPRESSION AND SUICIDAL BEHAVIOR

One of the fields of real scientifical interest is represented by the involvement of

imidazoline system in major depression and in suicidal behavior. Piletz et al., 2000 (2) reported a down regulation of I_2 receptors in frontal cortex of suicidal victims with major depression. In case of deceased patients with major depression the imidazoline receptor binding protein band (40 - 50kDa) from the hippocampus of the subjects with major depression was significantly lower compared to controls. An extremely interesting fact is that the amount of protein-receptors decreases not only in the brain but also in the platelets (2).

Differential analysis of the amount of receptor protein for I_1 and I_2 receptors in the brain of major depression deceased suicidal patients showed that there is also an imbalance in the expression of the two receptors subtypes in the brain and also in the platelets. In the brain, the amount of 45kDa protein corresponding to I_1 receptors increases with 51% in the brain of suicidal victims, whereas in major depression patients with no suicidal attempts it decreases with 40% (3). The I_2 receptor subtype has been especially involved in the pathogenic mechanisms of psychiatric diseases (4).

One of the extremely interesting characteristics of these binding situs (I_2) is that some of the situs are localized to a specific domain of monoamineoxidase. Thus, it could be influenced the metabolism of biogenic amines and especially of brain catecholamine. Morever, it has been raise the problem that agmatine (natural I_1 and I_2 receptor agonist) should be considered a new neurotransmitter (5). Imidazoline I_2 receptors have a role in antidepression activity and probably in preventing the apparition of depression. An I_2 receptors agonists, 2-BFI, a compound which selectively inhibits (MAO-A) has a pronounced antidepressive effect in case of experimental animal depression. 2-BFI (100-300 micromol/kg) significantly reduced the immortality time in the tail suspension test on mice. The I_2 receptors agonists, 2-BFI, as well as agmatine (agonist of both I_1 and I_2 receptors) (5-10 μmol/kg i.p.) potentates the antidepressant effect of agmatine. We consider that brain agmatine has a physiological role as an endogenous antidepressant as in mice exposed to FST the brain level of agmatine increases SSRIs (but not imipramine) determined an increase in agmatine brain level (6). Unlike I_2 receptors, which stimulatins determines antidepression effects, The I_1 receptors are increased in platlets but also on peripheral. Agmatinase, an inactivator of the putative endogenous antidepressant agmatine, is strongly upregulated in hippocampal interneurons of subjects with mood disorders (7).

The antidepressive effect of the selective serotonin re-uptake inhibirotors involves the imidazoline receptors activation. Regarding the mechanism of antidepression action of agmatine, it is considered as been produced on the following routes (which are activated upon imidazoline receptors activation):

a. agmatine reverses the imidazoline induced calcium concentration increase (8);
b. agmatine reverses the norepinephrine and dopaminic cell content;
c. agmatine inhibits the nitric oxide synthase and down regulates inducible nitric oxide synthase (4).

Also, it is possible that alpha-2 receptors are also involved in agmatine antidepressant activity, as this kind of action is reduced by agmatine (9).

ANXIETY

Anxiety is also influenced by the imid-

azoline system. Agmatine is considered as an endogenous neuromodulator (4). Intracerebroventricular, as well as intraperitoneal agmatine administration elicits anxiolitic-like effects (and also anticonvulsivant and neurotoxic action). This compound has also an anxiolitic effect at 300 μmol/kg s.c. (10). The antidepressant-like effect of tramadol in the mouse forced swimming test (FST) is partially mediated by imidazoline system stimulation in the brain (11). The imidazoline system (including I_1 and I_2 receptors) is also involved in modulating stress response (1). Both hypothalamic-pituitary-adrenal (HPA) axis and the activity of other cerebral structures are influenced (12). Agmatine is considered as an endogenous neurotransmitter, which has the ability to influence the response to stress factors on at least two ways: by stimulating I_1 and I_2 receptors and by acting on adrenergic receptors, such as α_2. In brain and also in spinal cord, has been identified agmatine decarboxylases (enzymes involved in agmatine decarboxylation and agmatine synthesis). Agmatine is packaged in presynaptic vesicles and released after neuronal depolarization (1). Intraperitoneal administration of agmatine elicit in rats anxyolitic effect on experimental acute stress. Agmatine reversed the increase of intracellular Ca^{2+} concentration in neurons after NMDA receptors activation (8). The activity of stress agents increase the activity of brain glutamatergic system and brain agmatine level and may determine a modulatory effect on these systems. Agmatine or agmatine-analogues administration may determine beneficial effects in stress or stress-related disorders (1). It has been proved that the anxiolytic-like effect of ethanol in rats is potentiated by pre-treatment with agmatine (10 – 20 mg/kg, i.p.) as well as other substances which increase brain agmatine concentration, such as l-arginine and DFMO (a ornitine-decarboxylase inhibitor) (13). Also, agmatine reduced withdrawal anxiety. In case of this effect of agmatine, stimulation of both I_1 and I_2 receptors is involved, as it is decreased by both efaroxan (1mg/kg, i.p.) and idazoxan (0.25 mg/kg, i.p.). There are some differences regarding the involvement of imidazoline system in depression and anxiety. In depressed patients a decreased I_2 receptors density in platelets and other tissues was found, whereas this is not present in patients with generalized anxiety disorder (14).

NEUROPROTECTION

Imidazolines are also involved in neuroprotection, which we consider important for protection in case of stress, including post-traumatic stress.

Agmatine reduced the glutamate induced neurotoxicity in cultured neurons by blocking the NMDA glutamate receptors activity. The other imidazoline drugs as antazoline and cirazoline fully prevented fully prevented the glutamate neurotoxicity. Besides this, agmatine attenuated the brain posttraumatic edema by decreasing the aquaporin 1 expression in various types of central ischemia (15). Another behavioral effect is the ultrasonic vocalization produced by rat pups in isolation. Neonatal ethanol exposure produced this behavior and agmatine reduced this effect (16). Moxonidin, another I_1 agonist, determined a protective effect on glutamate induced neurotoxicity (17).

STRESS

Regarding the complex involvement of imidazoline receptors in stress, it is worth

mentioning that a synthetic I_2-receptors agonist named BU224 increased the immuno-like reactivity in a lot of brain area (hypothalamic paraventricular nucleus, amygdala, locus coeruleus) in both naïve rats and restrained-stressed rats (18).

FOOD INTAKE

The central imidazoline system also seems to be involved in eating behavior. Clonidine (alpha$_2$ and I_1 agonist) injected into the median raphe nucleus in rats changed the food intake in the anxiety-like in rats (19). On the other hand, water intake doesn't seem to be influenced by imidazoline system (20).

PAIN BEHAVIOR

The I_1 receptors stimulation by moxonidine combined with some opioid agonists of μ receptors produced a spinal antinociceptive synergy and inhibits substance P-elicited behavior (21). We think that administration of moxonidine opioids association may be effective not only to manage the pain, but also to reduce pain-related anxiety.

CONCLUSIONS

Regulation of human behavior is dependent on lots neuromodulators or neurotransmitters, molecules with specific roles in central nervous system. Most of these molecules act on receptors present in neurons or nevroglia. Imidazoline system has permanent interactions with other brain neurotransmitters systems, and mainly with catecholamine system. Existent data suggest that interactions between imidazoline system and other neuromediators systems are essential in behavior regulation. Drugs acting as selective agonists and antagonists of imidazoline receptors will have clinical uses as behavior modulators in the future.

CLINICAL ANATOMY OF THE ESOPHAGOGASTRIC JUNCTION (Abstract): The esophagogastric junction is a controversial anatomical area, due to its sphincteric mechanism which does not show an obvious anatomical basis. The **aim** of this study is to investigate the anatomical components that endoscopically indicate the mucosal esophagogastric junction in hiatal hernia patients. **Material and methods**: The esophagogastric junction was investigated in 27 hiatal hernia patients undergoing surgery. Hiatal hernia is an extension of the stomach situated between the esophagogastric junction and the diaphragmatic indentation. The following types of hiatal hernia were found: sliding hiatal hernia (type I) in 4 patients (14,81%), rolling hiatal hernia (type II) in 2 (7,4%), mixed hiatal hernia (type III) in 12 (44,44%), type IV hiatal hernia in 4 (14,81%) and recurrent hiatal hernia in 5 (18,51%). Of the 27 hiatal hernia patients, 8 (29,6%) were operated using classical procedures: laparotomy – 6 (75%) and laparoscopic surgery – 2 (25%). **Results**: The angle of His cannot be used for marking the mucosal esophagogastric junction due to the severe damage of the lower esophageal sphincter in hiatal hernia patients. The squamocolumnar junction is displaced in hiatal hernia patients and was not an option for the study group. The distal end of the esophageal longitudinal palisading vessels needs medication (proton pump inhibitors that reduce the gastric acid production), in order to enhance the visibility of these vessels. The proximal end of gastric longitudinal mucosal folds proved to be the most reliable site to identify endoscopically the mucosal esophagogastric junction. **Conclusions**: The anatomical structure of the esophagogastric junction differs in hiatal hernia patients and these peculiarities are very important in surgery. **Key words**: ESOPHAGOGASTRIC JUNCTION, CLINICAL ANATOMY, HIATAL HERNIA

Joncțiunea eso-gastrică reprezintă o zonă anatomică extrem de controversată, din cauză că, deşi în regiunea aceasta care leagă esofagul de stomac nu s-a descoperit niciun sfincter muscular neted, există totuşi un mecanism funcțional care indică relaxarea şi contracția unui sfincter. Presiunea exercitată de joncțiunea eso-gastrică normală este extrem de importantă pentru digestie, prin controlul intrării alimentelor în stomac, dar şi prin blocarea revenirii acestora. Din cauza fiziologiei sale, care nu pare să aibă o bază anatomică, joncțiunea eso-gastrică rămâne o regiune a cărei microstructură nu este încă bine înțeleasă. Chiar dacă o serie de studii anatomice au demonstrat o uşoară creştere a stratului muscular circular din jurul joncțiunii eso-gastrice, anatomiştii resping totuşi utilizarea termenului „sfincter", dată fiind absența unei îngroşări a stratului muscular (1). Muşchiul diafragmatic din hiatusul esofa-

gian funcționează ca un sfincter (2). De fapt însăşi natura acestei zone de graniță între esofag şi stomac nu este clară, ea fiind considerată fie musculară, fie mucozală.

Dat fiind că joncțiunea eso-gastrică este investigată nu doar în anatomie, fiziologie, gastroenterologie şi chirurgie, ci şi în imagistică, imaginile obținute prin rezonanță magnetică nucleară au permis deja crearea unor modele computerizate tridimensionale (3) ale acestei zone care continuă să fie investigată şi în prezent.

În stările patologice, structura musculară a joncțiunii eso-gastrice, care formează sfincterul esofagian inferior, degenerează şi devine relaxată, provocând dilatarea esofagului distal şi a joncțiunii eso-gastrice. Acest proces duce ulterior la apariția herniei hiatale.

MATERIAL ŞI METODE

Studiul de față abordează anatomia joncțiunii eso-gastrice din perspectiva chirurgului practician şi cu scopul de a verifica metodele de identificare a joncțiunii eso-gastrice la pacienții cu hernie hiatală. Cercetarea s-a efectuat în perioada ianuarie 2007 – martie 2011, pe un lot de 27 de pacienți cu hernie hiatală voluminoasă operați la Secțiile Chirurgie I şi Chirurgie II ale Spitalului Universitar de Urgență Militar Central „Carol Davila", Bucureşti. Din cei 27 de pacienți cu hernii hiatale voluminoase, 8 (29,6%) au fost operați prin procedeele clasice. Dintre aceştia, în 6 cazuri (75%) s-a intervenit prin laparotomie de la început, iar în 2 cazuri (25%) s-a procedat la conversie prin chirurgie laparoscopică.

REZULTATE ŞI DISCUȚII

În lotul de pacienți luați în studiu, s-au identificat următoarele tipuri de hernii hiatale: hernie hiatală de alunecare (de tip I) la 4 pacienți (14,81%), hernii hiatale de rostogolire (de tip II), la 2 (7,4%), hernii hiatale mixte (de tip III), la 12 (44,44%), hernii hiatale de tip IV, la 4 (14,81%) şi hernii hiatale recidivate, la 5 pacienți (18,51%) (tab. I).

TABELUL I

Tipuri de hernii hiatale voluminoase incluse în lotul de studiu

Tipul de hernie hiatală	Nr. de cazuri	%*
I (de alunecare)	4	14,81
II (de rostogolire)	2	7,4
III (mixte)	12	44,44
IV	4	14,81
Recidivate	5	18,51

*Pentru valorile mai mici de 10, proporțiile sunt orientative.

Diagnosticarea pacienților a fost complicată de problema definirii joncțiunii eso-gastrice din punct de vedere endoscopic şi histologic. Manometria nu a reprezentat o opțiune pentru diagnosticarea herniilor hiatale, ci doar o metodă de evaluare a intervenției chirurgicale în varianta manometriei intraoperatorii sau postoperatorii, când presiunea sfincterului esofagian inferior (structura musculară a joncțiunii esofagiene) a fost apreciată la peste 20 mmHg.

Pentru identificarea liniei Z, numite astfel din cauza formei sale în zig-zag (4) – joncțiunea dintre mucoasa esofagiană şi cea gastrică – s-au observat principalele elemente anatomice ale zonei esofagogastrice pe lotul de 27 de pacienți cu hernie hiatală voluminoasă operați la Spitalul Universitar de Urgență Militar Central „Carol Davila", Bucureşti. Joncțiunea eso-gastrică este poziționată în stânga vertebrei T11, pe planul orizontal care trece prin vârful procesului

xifoid. Joncțiunea eso-gastrică joacă un rol extrem de important în prevenirea refluxului gastrointestinal, prin funcționarea corectă a sfincterului esofagian inferior (5).

La pacienții cu hernie hiatală s-a observat că joncțiunea scuamocolumnară este dislocată proximal, în diverse grade, față de joncțiunea eso-gastrică. Se ştie că la persoanele sănătoase, joncțiunea eso-gastrică mucosală se suprapune pe joncțiunea scuamocolumnară.

Unghiul lui His nu s-a putut folosi pentru identificarea joncțiunii eso-gastrice la pacienții cu hernie hiatală voluminoasă, deoarece în cazul lor întregul sfîncter esofagian inferior este distrus în diferite grade, iar acest reper este lezat.

Capătul proximal al pliurilor gastrice longitudinale, un reper endoscopic al joncțiunii eso-gastrice mucozale (6), este strâns legat de joncțiunea eso-gastrică musculară. La persoanele sănătoase, joncțiunea scuamocolumnară este localizată la evaluarea endoscopică la 2 cm de capătul proximal al pliurilor longitudinale ale mucoasei gastrice. Pentru pacienții cu hernii hiatale, capătul proximal al pliurilor gastrice longitudinale este considerat în cadrul endoscopiei un reper anatomic fix al joncțiunii eso-gastrice mucozale (7). Obiecțiile care se pot aduce acestui reper se referă la faptul că pliurile mucoasei gastrice pot fi aplatizate în mod artificial prin dilatarea indusă endoscopic sau modificate în timpul respirației. Observațiile obținute la pacienții noştri sugerează că acest reper poate fi totuşi folosit la pacienții cu hernie hiatală voluminoasă.

Capătul distal al vaselor esofagiene longitudinale dispuse în palisadă reprezintă o altă modalitate de identificare endoscopică a joncțiunii eso-gastrice, care a fost folosită până în prezent în Japonia (8). Astfel, în esofagul distal, există multe vene longitudinale paralele, care străbat *lamina propria* şi se termină în joncțiunea mucozală a stomacului. Aceste vene sunt vizibile în timpul endoscopiei ca vase dispuse în palisadă, vizualizarea este însă posibilă numai în timpul unei inspirații profunde. Întrucât asemenea vase nu apar şi la nivelul stomacului, ele pot fi utilizate ca reper al joncțiunii eso-gastrice. Nu am aplicat această metodă la pacienții luați în studiu, din cauză că ar fi trebuit să le administrăm pacienților inhibitori de pompă de protoni, pentru a reduce nivelul de acid gastric şi pentru a îmbunătăți astfel vizibilitatea acestor vase, mai ales la cei care prezintă esofagită indusă de hernia hiatală voluminoasă.

Joncțiunea scuamocolumnară, pe baza căreia la subiecții normali se poate identifica joncțiunea eso-gastrică, nu a putut fi luată drept reper la pacienții cu hernie hiatală voluminoasă, deoarece în cazul acestora joncțiunea scuamocolumnară este dislocată şi se poziționează deasupra joncțiunii eso-gastrice mucozale.

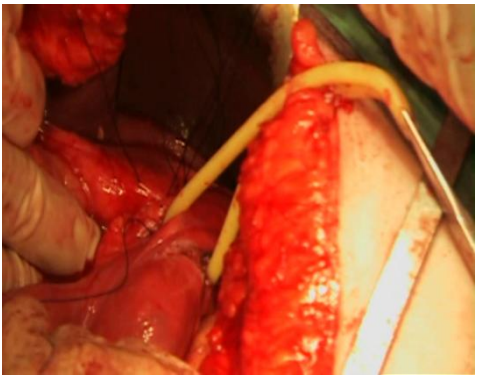

Fig. 1. Joncțiunea eso-gastrică la un pacient cu hernie hiatală voluminoasă

CONCLUZII

Anatomia joncțiunii eso-gastrice poate suferi modificări ample atât în procesele patologice maligne, cât şi în cazul patolo-

giei benigne. Dacă achalazia cardiei implică mai ales o îngroşare a peretelui esofagian inferior datorată hipertrofiei musculare circulare de la nivelul sfincterului esofagian inferior, în cazul herniilor hiatale modificările anatomice sunt diverse şi se datorează migrării joncțiunii eso-gastrice sau/şi a unei porțiuni de stomac din abdomen în mediastin. Herniile hiatale voluminoase, in care cel putin 30% din stomac, singur sau însoțit de alte organe, se află în cavitatea toracică, pot determina alterări profunde ale anatomiei locale, uneori foarte greu de restabilit. Astfel, identificarea esofagului şi a joncțiunii eso-gastrice se pot face numai după disecția minuțioasă a sacului de hernie şi abdominalizarea viscerelor.

Studiul de față a demonstrat că la pacienții cu hernie hiatală voluminoasă capătul distal al vaselor esofagiene longitudinale dispuse în palisadă s-a dovedit un element anatomic util în identificarea endoscopică a joncțiunii eso-gastrice.

ASSOCIATION OF ALBUMINURIA WITH ADIPOKINES, INFLAMMATION AND INSULIN RESISTANCE IN NON-DIABETIC SUBJECTS (Abstract): The objective of this study was to evaluate the association of traditional cardiovascular risk factors, adipokines, inflammation and insulin resistance with low-grade urinary albumin-to-creatinine ratio (ACR) in nondiabetic, healthy subjects. **Material and methods**: The study included 117 healthy subjects (64 men and 53 women), who were classified according to their body mass index (BMI) into three groups: lean (BMI<25 kg/m^2), overweight (25≤BMI<30 kg/m^2) and obese (BMI≥30 kg/m^2). **Results**: ACR was higher in obese men and women compared to overweight and lean men and women (men – 3 mg/g vs. 6.1 mg/g vs. 8.9 mg/g, p=0.018; women – 2.1 mg/g vs. 6.7 mg/g vs. 9.1 mg/g, p=0.03). In univariate analyses ACR was associated in obese men with adiponectin (r=-0.43, p=0.021) and systolic blood pressure (r=0.51, p=0.006) and in non-obese men with systolic blood pressure (r=0.39, p=0.041). In women systolic blood pressure was the only determinant both in obese (r=0.49, p=0.022) and non-obese subjects (r=0.42, p=0.04). **Conclusions:** Adiponectin is an important mediator of low-grade albuminuria in obese, non-diabetic men. **Key words**: LOW-GRADE ALBUMINURIA, ADIPONECTIN, OBESE, INFLAMMATION

Microalbuminuria este definită ca prezenţa unei eliminări urinare cuprinsă între 30-300 mg în urina colectată în 24 ore, sau ca raportul urinar albumină/creatinină, dintr-o emisie spontană de urină, cuprins între 30-300 microg/mg (1).

Datele epidemiologice arată că prevalenţa microalbuminuriei la persoanele adulte este de 30% la subiecţii cu diabet zaharat şi de 10-15% la subiecţii nediabetici (2). Eliminarea urinară de albumină, rezultat al creşterii permeabilităţii la nivelul endoteliului renal, este un marker al disfuncţiei endoteliale sistemice (2). Cossonert al (3) au demonstrat la un număr de 87 pacienţi cu diabet zaharat tip 2, faptul că subiecţii cu microalbuminurie, comparativ cu cei normoalbuminurici, asociau o afectare severă a răspunsului vasodilatator endoteliu-dependent la nivel coronarian. Creşterea eliminării urinare de albumină se asociază cu majoritatea factorilor de risc cardiovasculari: hiperglicemie, hipertensiune arterială, disfuncţie renală, dislipidemie, hiperhomocisteinemie, creşterea aportului proteic, fumat, prezenţa markerilor de fază acută. Dintre aceştia, diabetul zaharat şi hipertensiunea arterială sunt principalii factori

de risc pentru apariția microalbuminuriei (1). Microalbuminuria se asociază cu creşterea riscului cardiovascular atât la subiecții cu diabet zaharat, cât şi la subiecții nediabetici (4,5,6,7,8).

Studiile efectuate la subiecții nediabetici au arătat faptul că există o corelație pozitivă între eliminarea urinară de albumină, la valori mai mici decât valoarea prag pentru stabilirea diagnosticului de microalbuminurie şi riscul de apariție al afecțiunilor cardiovasculare (9,10,11,12).

O lungă perioadă de timp, s-a considerat că țesutul adipos are un rol pasiv, de depozitare, sub formă de trigliceride, a excesului de energie. Odată cu identificarea produşilor de secreție ai adipocitului, denumiți adipokine, cu acțiuni atât locale, cât şi la distanță, a devenit clară legătura dintre țesutul adipos visceral şi factorii de risc metabolici. Adipokinele (13,14) sunt principalii mediatori ai legăturii dintre obezitate şi modificările metabolice. Aceşti produşi de sinteză ai țesutului adipos au atât efecte directe cât şi indirecte în reglarea apetitului, a metabolismelor glucidic, lipidic şi proteic şi a procesului inflamator. La subiecții obezi, majoritatea adipokinelor sunt sintetizate în exces, conducând la accentuarea disfuncției metabolice. Adiponectina este un hormon unic al țesutului adipos cu efect antidiabetic, antiinflamator şi antiaterogen (15,16). Concentrația plasmatică a adiponectinei este scăzută atât la subiecții obezi (17), cât şi la subiecții cu diabet zaharat tip 2 (18). Rolul antiaterogen al adiponectinei se manifestă la nivelul tuturor etapelor procesului aterosclerotic: disfuncție endotelială, formarea şi progresia plăcii de aterom, ruperea plăcii de aterom şi formarea trombusului (19,20). Date recente arată că adiponectina are un rol cheie în medierea relației dintre țesutul adipos şi microalbuminurie, asociere ce poate avea un rol important în creşterea riscului cardiovascular la subiecții obezi (21, 22, 23, 24).

În acest studiu am evaluat corelațiile dintre adipokine (adiponectină şi leptină), markeri inflamatori (PCR-reactivă cu sensibilitate crescută), markeri ai sensibilității la insulină (insulină şi HOMA-IR) şi eliminarea urinară de albumină la subiecți nediabetici, în funcție de indicele de masă corporală.

MATERIAL ŞI METODĂ

Subiecți

În studiu am incluşi un număr de 117 subiecți (64 bărbați şi 53 femei), nediabetici, fără afecțiuni cardiovasculare, selectați pe o perioada de 1 an (01.02.2009-30.01.2010) atât din rândul pacienților aflați în evidența Ambulatoriului Spitalului Clinic Colentina – Cabinetul de Diabet, Nutriție, Boli Metabolice, cât şi din rândul pacienților internați în Secția de Diabet, Nutriție, Boli Metabolice a Spitalului Clinic Colentina. Înainte de includerea în studiu, toți subiecții au semnat consimțământul informat. Participanții la studiu au fost împărțiți în funcție de indicele de masă corporală în următoarele trei grupe: obezi (IMC≥30 kg/m2) – 56 subiecți (31 bărbați şi 25 femei), supraponderali (25≤IMC<30 kg/m2) - 43 subiecți (24 bărbați şi 19 femei) şi normoponderali (IMC>25 kg/m^2) - 18 subiecți (9 bărbați şi 9 femei). Au fost excluşi subiecții fumători, aflați în tratament hipotensor, hipolipemiant, cu neoplasm, afecțiuni endocrinologice (acromegalie, hipotiroidie, hipertiroidie, sindrom Cushing), pancreatită acută, pancreatită cronică, hemocromatoză, pancreatectomie, hepatită cu virus B, hepatită cu virus C, boli cronice inflamatorii sistemice, cu va-

lori ale tensiunii arteriale ≥ 170/100 mmHg, trigliceridelor ≥ 400 mg/dL, colesterolului total ≥ 300 mg/dL şi creatininei serice ≥ 1,5 mg/dL.

Determinări de laborator

Probele de sânge au fost prelevate în cursul dimineții, între orele 8.00-10.00 (după repaus alimentar de minim 8 ore), pentru determinarea: hemoleucogramei, glicemiei, colesterolului total, HDL-colesterol, trigliceride, hemoglobina glicozilată (HbA1c), acid uric, fibrinogen, TGO, TGP, GGT. LDL-colesterol a fost calculat folosind formula Friedewald (LDL-colesterol = colesterol total – (HDL-colesterol + triglicerid/5). Adiponectina, leptina, proteina C-reactivă înalt sensibilă (hs-CRP) şi insulina au fost determinate folosind kituri produse de către DRG International, Inc., prin tehnica ELISA, utilizând un autoanalizator Dynex. Analizele au fost efectuate în cadrul Laboratorului Gral Medical Colentina. Sensibilitatea la insulină am evaluat-o folosind HOMA-IR (homeostasis model of insulin resistance) după următoarea formulă: glicemia „à jeun" (mg/dL) x insulinemia „à jeun" (µU/mL)/ 405. Folosind această formulă, subiecții cu valori scăzute ale HOMA-IR prezintă un grad mai mare de insulinosensibiliate. Masa de țesut adipos am calcalat-o prin metoda bioimpedanței, folosind un analizor Omron BF500.

Prelucrarea statistică

Analiza statistică am realizat-o cu ajutorul aplicațiilor GraphPad Instant 3, NCSS 2004, PASS 2002 şi Microsoft Excel 2003. Variabilele continui cu distribuție normală, le-am prezentat sub formă medie şi deviație standard (DS), datele cu distribuție non-normală (adiponectina, leptina, hs-PCR, insulina, HOMA-R, raportul albumină/creatinină urinară) le-am prezentat sub formă mediană şi diferența între quartila a treia şi prima quartilă. Variabilele continui au fost testate pentru distribuția normală cu testul Kolmogorov-Smirnov. Compararea mediilor între două grupuri, am realizat-o folosind testul *t-Student*, pentru variabilele continui cu distribuție normală şi folosind testul Mann Whytney U pentru variabilele continui cu distribuție non-normală. Pentru compararea mediilor între trei sau mai multe grupuri, am folosit testul de analiză a variației (ANOVA), pentru variabilele continue cu distribuție normală şi pentru variabilele cu distribuție non-normală testul Kruskal-Wallis, cu testul Dunn pentru comparațiile multiple dintre variabile. Analiza de corelație între variabilele continui, am efectuat-o prin determinarea coeficienților de corelație Pearson, variabilele continui cu distribuție non-normală fiind transformate logaritmic (log_{10}). Pentru toate testele, pragul de semnificație statistică a fost de p=0,05.

REZULTATE

Caracteristicile subiecților incluşi în studiu

Caracteristicile subiecților incluşi în studiu sunt prezentate în tabelul 1. Nu au existat diferențe între grupele analizate în ceea ce priveşte vârsta. Valorile medii ale următorilor parametri cresc semnificativ statistic odată cu indicele de masă corporală: circumferința abdominală, procentul de țesut adipos, glicemia bazală, tensiunea arterială sistolică, tensiunea arterială diastolică (diferența a fost semnificativă doar în cazul bărbaților), trigliceridele, TGO, TGP, GGT, acid uric. Procentul de masă adipoasă a fost semnificativ mai mare la femei comparativ cu bărbații la toate cele trei grupe analizate. Valoarea medie a HDL-colesterol a scăzut odată cu creşterea IMC. În ceea ce priveşte concentrația markerilor inflamatori, rezultatele obținute

arată, la ambele sexe, creşterea medianei hs-CRP şi a valorilor medii ale numărului de leucocite, odată cu creşterea indicelui de masă corporală. În cazul adipokinelor, la ambele sexe mediana adiponectinei scade odată cu creşterea indicelui de masă corporală, în timp ce mediana leptinei creşte odată cu creşterea indicelui de masă corporală. În ceea ce priveşte evaluarea insulinosecreției şi a sensibilității la insulină, atât mediana insulinemiei bazale, cât şi a HOMA-IR cresc odată cu creşterea IMC.

TABELUL I

Caracteristicile subiecților incluşi în studiu

	Normoponderali	**Supraponderali**	**Obezi**	**p**
Vârsta (ani)	54,6±7,1	54,5±9,4	52,9±8,7	0,67
